The refining of lead bullion as performed by the International Lead Refining Co. is illustrated by a flow-sheet and samples of the intermediate and end products, together with analyses of the same. Large photographs serve still further to illustrate various stages of the process.

The copper produced by the Anaconda company is largely refined at the Raritan Copper Works at Perth Amboy, New Jersey. A portion of the output is refined at the Boston & Montana Reduction Works of the Anaconda company at Great Falls, Montana. The process of copper refining is shown by means of samples of the various intermediate products, with a complete collection of the common shapes of finished copper from each of the above refineries. The refining of silver slime and various by-products, such as nickel salts, selenium, and tellurium, resulting therefrom, is also shown, as well as manufactured copper and brass articles, the latter being contributed by the American Brass Co. and the Bridgeport Brass Company.

The 'safety-first' work of the company also has a place. Copies of *The Anode*, the safety-first publication of the Anaconda company, and of *The Ingot*, which fulfills a similar function at the Raritan Copper Works, are on hand for distribution.

OPERATIONS of the Amalgamated Zinc (De Bavay's) flotation plant on Broken Hill tailing during the 28 days ended January 30, were as follows: tailing treated, 18,608 tons; zinc concentrate produced, 4763 tons, assaying 49.3% zinc, 8.7 oz. silver, and 5.6% lead; and 36 tons lead concentrate, assaying 54.5% lead, 56.9 oz. silver, and 14.5% zinc. The estimated income was $67,000, and net profit $9500.

Leaching of Copper Ores by the Hoffman Process

By FREDERICK J. POPE

*In our first study of leaching work, we had to decide: The solvent we would use; how we would precipitate the copper from the solution, and what we would do with the iron in the electrolyte. Without going into the details of the reasons, we decided that sulphuric acid would be the most satisfactory solvent, and that we would recover the copper from the solutions by electro-deposition. As to how we would take care of the iron in the electrolyte, we had to choose between controlling the iron (keeping it in the ferrous state) in the solution, and eliminating it from the solution. The removal of the iron appeared to offer the more attractive field.

Briefly, the method involved leaching with sulphuric acid, removing a portion of the iron from the solution, and precipitating the copper electrolytically.

Regarding the leaching itself, I do not think I could say anything that would be of any particular interest. There are certain factors which govern the extraction of copper from an ore, and when these factors are given due consideration, I think we can get about the same extraction with one process as with another.

In considering how to remove iron from the electrolyte, we were reminded of the work which had been done by Hoffman at Argentine, where he precipitated iron from bluestone solution. Hoffman accomplished this by heating the solution in a suitable tank, agitating with air, and adding copper in an oxidized form. I think he used a roasted lead-copper matte. This work of Hoffman's gave us our idea for the removal of iron from the solution.

For the copper oxide necessary in this work we have used high-grade copper carbonate ore, oxide formed by the roasting of cement copper, roasted high-grade sulphide ore, also roasted copper sulphide concentrates. In our demonstration plant (10 tons daily capacity of carbonate ores) we used roasted concentrate. The concentrate was roasted in a small Wedge furnace, the results obtained being far better than those attained in our preliminary work when we roasted the same class of concentrate in a laboratory muffle-furnace.

In order to obtain a satisfactory reaction between the copper oxide and the iron, etc., in the solution, it is imperative to have the oxide material very finely divided. The roasted concentrate we used was ground in a small Abbé mill. We found that with a 5 or 6-hours grinding we obtained a product 93% of which would go through a 200-mesh screen. Probably if we had had time to investigate this grinding operation, we might have found that it was not necessary to grind for 5 hours, but owing to the shortness of the period at our disposal for securing results, we did not have the opportunity to bring this operation down to the shortest time-limit.

From the Ajo carbonate ore we removed a little more than 2 lb. of iron per ton of ore treated. In order to keep the iron in the solution below the percentage deleterious to electrical efficiency, it was necessary to treat approximately one-quarter of the solution. We found that by manipulating the solution going on and off the ore in a certain way we could concentrate a large proportion of the iron in a certain part of the solution. This was accomplished as follows: The first solution going on the ore carried about 2.5% free acid and was kept on the ore by circulating until it was approximately neutral. This neutralizing precipitated from the solution on the ore a considerable proportion of the iron, alumina, etc. This neutral solution was drawn from the ore, and after acidification by electrolyte coming off the electrolytic vats was sent to electrolytic vats for precipitation of the copper. As the first solution was withdrawn from the leach it was replaced by fresh solution. This fresh acid solution not only removed some more of the iron from the ore, but also picked up the iron which had been precipitated from the first solution used. This second solution now high in iron was circulated until it was nearly neutral, when it was replaced by fresh solution carrying 4 to 4.5% free acid, which completed the leach. The total leaching period averaged about 80 hours. The solution high in iron, etc., was sent to that part of the plant where removal of iron and other impurities was accomplished.

In purifying the solution it was first heated to 195°-200°F. When this temperature was attained, agitation with air was begun and the finely ground oxide material was gradually added. Maintenance of a temperature of about 195°F. and agitation with air was continued for 3.5 hours. During the first hour all the ferric iron was precipitated. The removal of the ferrous iron was slower and we found that it was not advisable to endeavor to precipitate it all. In 3.5 hours we easily precipitated 90% of the total iron and at the same time removed 65 to 75% of the alumina, 50% of the manganese, and any arsenic, antimony, and bismuth.

After the above operation the pulp was passed through a Schreiber wooden filter-press. The solution came out beautifully clear and was sent to the high-acid electrolytic circulation-system. We anticipated that with the precipitate produced we might have trouble with the filter-cake; that it would be slimy and difficult to handle. We did not find it so. The cakes were two inches thick, firm, washed well, and the amount of copper in the form of unused oxide was well

*This record of investigations made by Messrs. Frederick J. Pope and A. W. Hahn was submitted by the former at the January meeting of the New York section of the American Institute of Mining Engineers.

within commercial limits of metallurgical work.

As chemists are well aware, when iron sulphate, aluminum sulphate, etc., react in the agitation-vat with the copper oxide, they give up their acid radicals to the copper, forming copper sulphate, which in the electrolytic vats yields sulphuric acid, so that the only loss of acid is that due to combination with the alkalies and that due to loss by entrainment in the tailing. This acid loss we found we could easily replace by a proper control of the roasting of the concentrate in the Wedge furnace; that is, we could so control the roast as to maintain in the calcine sufficient copper sulphate either as water-soluble sulphate or as basic sulphate to compensate for the acid-losses to which I have referred.

Regarding the electrolytic part of the work, we simply followed standard vat-house liberator-vat practice. Our anodes were antimonial lead, 4% antimony. We tried both grids and sheets. With the grids our voltage was 0.3 volt higher than with the sheet anode, and we discarded the grids in favor of the sheets.

With reference to the use of a lead anode, I might say we commenced our work with some apprehension, fearing that there might be a serious loss of lead. We made a number of protracted tests and as a result we calculate that the cost for lead anodes at Ajo with lead at 8c. per pound would be less than 0.2c. per ton of ore treated.

In the process I have outlined there is really nothing new or novel. It simply consists of an idea picked up here and another there, and the putting of these various ideas together.

If we were to criticize the process, the pros and cons might be summed up about as follows:

Advantages:

a. Simplicity.
b. Every step in the process has been in use in commercial plants for years.
c. Saturated solutions avoided.
d. Wash water not excessive, and if it should become so, it can be regulated.
e. Impurities that would injure the quality of the electrolytic copper are eliminated from the electrolyte.
f. Acid control very simple.
g. No step in the process is dependent upon fine adjustments.

Disadvantages:

a. High and low acids used. This necessitates more solution-storage vats, more solution lines, and more pumps than if a single solution were used.
b. There is an extra operation: namely, purification of electrolyte, which involves the installation of a roasting-furnace, boilers, compressor, and filter-press.
c. The lead anodes will probably have to be changed at the end of four or five months, since the lead peroxide scale will increase the voltage.

J. Parke Channing, commenting on the foregoing, said: The problem presented in the Miami district is a little different from that in the districts mentioned in this discussion, inasmuch as the ore to be treated there is one which is a mixed chalcocite and carbonate. The gangue is particularly free from any impurities that go into solution, but the fact that both chalcocite and carbonate are present makes it a difficult problem. The particular ore deposit upon which we worked was that of the New Keystone, but the same class of ore existed in the Miami and also in the Inspiration. The problem therefore presented to us was either a straight leaching one, which would have to be preceded by dead roasting, or else it would be a mixed process, water-concentration followed by leaching, or possibly leaching followed by water-concentration; and then finally, if flotation came in, we might have to make three bites of the cherry, that is, use water-concentration, flotation, and leaching. You can readily see there would be a great many combinations; whether it would be desirable to leach first, then concentrate by water, and then float, or whether it might be desirable to make the sequence different, we do not know. This Keystone ore averages about 2¼% copper, of which anywhere from 30 to 40% is oxidized. After making a number of concentration tests we decided upon attempting a dead roast; in other words, converting all the copper into a soluble form and leaching it.

R. C. Canby said: The only thing I can think of which has not been mentioned is the circulation of the electrolyte. In our electrolytic work I designed the cells so that the solution, instead of flowing lengthwise against the flat surfaces of the anodes and cathodes, flowed crosswise. In that way, in the use of sulphurous acid gas, I had hoped, by having a rapid circulation, to use a much smaller quantity of both copper and the depolarizing element in the electrolyte, with a correspondingly stronger current, and also to be able to precipitate the copper without heating the electrolyte. I was able to use a current density as high as 10 or 12 amperes per square foot with the temperature of the electrolyte about 18° to 20°C., and get a satisfactory coherent deposit. I think that was the only novelty in the electrolytic work.

As regards roasting in an oil furnace, the problem was to use our 14°B. fuel-oil, to be burned at a temperature of 2000°, and yet keep our ore-bed at not to exceed 800° to 1000°C. I accomplished this by using a furnace similar to that used for the Huntington & Heberlein process at El Paso, and at three other American smelting plants, the hearth revolving past the flame, so that I was able to roast the ore without at any time bringing the temperature of the roasting ore above the desired 1000°C., whereas the fuel was being burned at about 2000° or a little over. The furnace was entirely of reinforced-concrete construction and stood well.

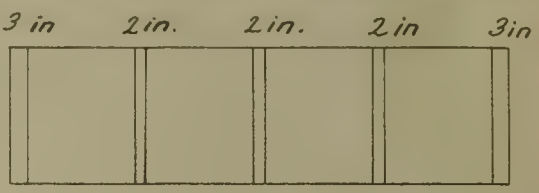
It would be much better if all of the oxides could be treated in the present plant, and we are now working to that end, so as not to have a separate installation for the semi-oxidized ores.

A Temporary Zinc-Box

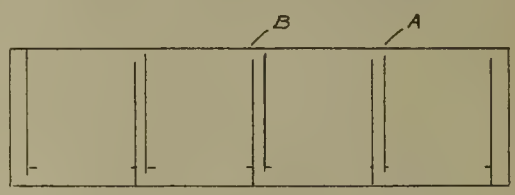
By A. W. ALLEN

The following description of a simple type of zinc-box refers to an instance when the operation of a newly erected plant in an outlying district in South America was delayed on account of the non-arrival of the necessary equipment. The only material available for the purpose was 18-gauge flat galvanized iron in 3 by 7-ft. sheets, and the boxes were made at the rate of two a week by two (native) tinsmiths, two helpers, and a 'handyman.' When completed and in position they were neat in appearance, and conveniently proportioned with regard to dressing and cleaning up, and had a capacity of 18 cu. ft. per box.

The two pieces forming the bottom and sides are first riveted together, allowing an inch overlap. A centre line is then drawn lengthwise of the sheets and parallel lines made on each side at distances of 11½ in. from the centre line. The sides are then bent up at right angles, keeping exactly to the marks. The two ends are next cut and bent (Fig. 1); one of them having a hole for a discharge pipe cut in it about 8 in. from the top. The discharge arrangement is best and easiest made by taking a short 2-in. nipple and using backnuts on each side with rubber washers. The nipple should screw into the discharge hole. The ends are next riveted on. A slip-ring of ⅜-in. round iron is next made the exact outside measurement of the box, the loose ends being welded together. This is then slipped over the top of the box, and the inch at sides and ends allowed for the purpose is then hammered around the iron and finally soldered. All points on the outside of the box are then soldered. The inside box is now carefully marked for the division plates. The sides and bottom of the division plates must be all bent one way, and the rivets necessarily come inside the compartments and not in the divisions between the latter. Angle iron 1 by 1 by 20 in., made from the same galvanized iron, is used to support the screens, and is fixed to the division plates before the latter are put in position. Their position on the plates is shown in the section. Holes for ½-in. bolts are next cut 1½ in. from each end on both sides of the box, about four inches from the top and four inches from the bottom of the box. A pair of holes are also cut in each side of the box at the centre, and also four inches from the top and bottom. These holes are for the legs (see drawing in perspective). The holes are filed down evenly, and any projecting edges are hammered flat. The legs are made from 2 by 3-in. Oregon pine, the outer pieces being 38 in. long, cut down ½ in. deep on the broad side for a distance of 22 in. Below this point a cross-piece 22 in. long (also 2 by 3 in.) is simply nailed on with 5-in wire nails. The legs are then placed in position and marked for the bolt-holes, care being taken that the box sets well on the stringer. The legs are then bored and replaced. Twelve bolts ½ by 2½ in. are needed for each box, each with two iron and one ⅜-in. rubber insertion washer. The washers should fit tight on the



PLAN.



SECTION.

FIG. 1.

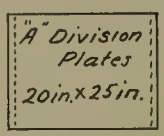


FIG. 2.

FIG. 3.

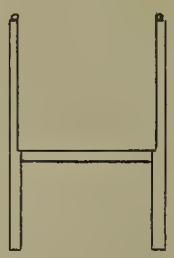

FIG. 4.

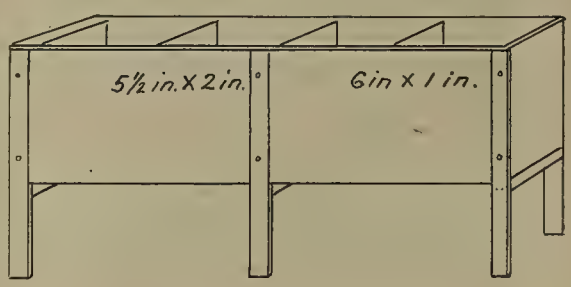


PERSPECTIVE DRAWING.

bolt, and are placed next the box on the inside, an iron washer coming inside them and then the head of the bolt. The extra iron washer is used outside, and a tight joint results if ordinary care be taken. The *B* division plates are then put in and riveted, and the joints soldered. Finally, the *A* division plates are put in and the joints soldered.

For the discharge arrangements a number of plates, one for each compartment, of $\frac{3}{16}$-in. iron were taken, $2\frac{1}{2}$ in. square. In the centre of each of these a hole was punched and tapped for 1-in. pipe. At the corners of each plate a small hole was punched to take a galvanized-iron roofing-bolt. Iron plug-cocks, 1-in., were used with a short nipple in each. This was screwed tight into the plate and the pipe projecting was sawed off and filed down smooth. One-inch discharge-holes were made in the bottom of each compartment, preferably near one side of the box. The plates are bolted on from the outside, the semicircular screw-heads of the bolts being inside the compartment. The plates should be perfectly clean and free from grease, and be soldered in together with the head of the bolts.

To arrange the box on a sloping floor, possibly sloping in more than one direction, cut a number of wedges of varying thickness, about $1\frac{1}{2}$ by 2 in. Place these under the legs of the boxes when the latter are where they will be eventually required, so that the plates are level and the boxes have a slight fall from head to discharge in the length. Take a block of wood slightly more than the amount the highest leg is off the ground and then mark all the legs, keeping the block on the ground and against the leg. The legs are then cut at the marks and the box replaced.

Sociological Work by the Phelps-Dodge Companies

The annual reports of Phelps, Dodge & Co.'s subsidiary companies contain the following notes on the interest taken in employees' welfare:

Copper Queen, Arizona. Accidents causing loss of time during 1914 were as follows:

	Bisbee.	Douglas.
Fatal	7	none
Serious	121	19
Minor	1320	175

The first-aid and safety department, under the management of Wallace McKeehan, safety inspector, did conscientious and efficient work.

The annual report of the state mine inspector for the year 1914 shows a smaller percentage of injuries of all kinds among employees of the Copper Queen than among the men of any other of the large mines of the state.

As applicants for underground work are now required to pass a physical examination, the higher physical condition of the men, combined with the rules of prudence and scrutiny which the safety-first practice imposes, not only on the men but on the companies, will certainly in time reduce the death rate and accident list below its present appalling figure.

The Employees' Benefit Association had an income of $43,172, of which members contributed $35,296 and the Copper Queen company $7500. Deaths absorbed $17,640; accidents, $13,290; sickness, $20,945; and general expenses, $3099. The year started with a balance of $17,503, and ended with $5700. The Company will increase its payment to $12,500 per year.

Nineteen employees have taken advantage of the pension system offered by the Company. During the eight months of its operation, $6182 has been paid to old employees.

Dr. F. E. Shine, superintendent and chief surgeon of the hospital department, submits the following report of work during the year: Income from fees, $88,783, and expense of maintenance, $89,380, leaving a deficit of $596. The work at Bisbee consisted of the following: patients admitted, 618; patients cared for, 980; births, 58; deaths, 43; total meals and diets, 53,358; hospital operations, 246; dispensary operations, 320; house calls, 12,451; dispensary calls, 39,488; examinations for Employees' Benefit Association, 2055; and X-ray pictures taken, 472; and at Douglas: house calls, 9615; dispensary calls, 20,023; operations, 61; births, 60; and deaths, 23. The staff consists of 10 physicians and surgeons, seven being stationed at Bisbee and three at Douglas. Outside of the regular practice of the department, the staff continues to make examinations for the benefit association and reports under the compensation law. During the year physical examinations of all applicants for work in the mine department has been made and recorded. A new dispensary building was completed and turned over to the hospital department by the Company on October 1.

At the Copper Queen smelter, safety work has been of great interest to everyone on the plant, and a great many devices have been installed, most of them suggested by the men themselves.

Detroit, Arizona. The general health of the camp was good. There was an epidemic of scarlet fever in the spring, but no fatalities. Only two cases of typhoid originated in Morenci during the year, and both of these were mild. The improved sanitary condition is due to the extension throughout the property of a sewer system.

The first-aid class for 1914 was started in January with an attendance of over 50, but it is difficult to sustain the interest of the men at large in its movements.

The average number of employees in the various departments for the year was 1438.

Stag Cañon Coal Mine, New Mexico. Lessons and practice in first-aid work are made compulsory with certain employees in each mine. The men, of course, are paid for the time they are employed in practice. A monthly dinner is well attended by the heads of the various departments, mine bosses, inspectors, and others, as a preliminary to the reading of papers and a general discussion on local and general technical subjects.

CONCENTRATES

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Babbitt metal contains 67% tin, 22% antimony, and 11% copper.

Zinc-shaving consumption in Western Australian cyanide plants amounts to about 75 tons per month.

Gasoline being short in Germany, sugar-beet alcohol is being produced for use in automobiles and aeroplanes.

Contractors in the Broken Hill South mine last year earned $4.36 as miners, and $3.48 per eight-hour shift as trammers.

Normal faults are those in which the rock forming the hanging wall of the fault has moved downward along the foot-wall of the fault.

Sectionalized rolls are made up to 12 by 24-in. size. The spare shells for this size would weigh about 350 lb. each, which is almost a limit for mule transportation.

Blood poisoning may easily be caused by having some skin knocked off any part of the body, and then rubbing the wound with dirty hands that may be infected.

Cost of filling stopes at the Broken Hill South mine in 1914 was 90c. per cubic yard of filling, and 20c. per ton of crude ore extracted. This included all charges on handling 25,698 tons of residue and ash.

Oil shales in Scotland yield from 20 to 30 gallons of crude oil per ton, and those of New South Wales yield from 60 to 120 gallons. The distilling-retorts used in Scotland are not suitable for the richer Australian shale.

Corrosion of brass is due to dezincification, the chemical and mechanical action being subsequent. Such deterioration proceeds faster in unannealed than in the annealed alloys. Iron and lead in small quantities stimulate corrosion.

Many unusual mining methods are practised in the Joplin zinc-lead district of Missouri. One of the latest is the idea of L. C. Morgan, at Duenweg, who owned a drill-rig, and during sinking placed it against the shaft and used it as a hoist.

Gold production of the North Star mines, Grass Valley, California, from May 1884 to the end of 1914 amounted to $16,360,776 from 1,248,534 tons of ore, an average of $13.104 per ton. Of this total, $6,219,236 was profit, and $4,537,040 was distributed in dividends to the shareholders.

Of the total recovery of gold at the North Star mill, Grass Valley, California, in 1914, 79.04% was by amalgamation, and 20.96% by cyanidation. The tailing from the cyanide plants assayed 30.5c. per ton, making a total loss of $30,500, or about 3% of the total gold content of the ore.

Locators of coal-lands in Alaska under the laws prior to the passage of the Leasing Act approved October 20, 1914, are permitted to carry their claims to a final determination in the proceedings now pending before the Department of the Interior. The act provides that no lease shall be made of a pending claim until after it is finally disposed of by the Department adversely to the claimant.

Lead poisoning sometimes occurs in manufacturing storage batteries. An ordinary storage battery consists of plates of lead, or of lead grids, covered with a lead oxide paste. In making the plates or grids the worker is exposed to the dust of the metallic lead and to its fume when melted. By using hoods and exhausts over kettles and by keeping the work-places strictly clean, these dangers can be much reduced. Making and applying the paste involve handling lead oxides, which are much more dangerous than handling metallic lead. The oxides must first be mixed, which is a dusty job, and then made into paste. Both these operations can be done by machinery under cover, thereby greatly reducing the danger to the worker. In most of the plants recently investigated in the United States, according to the Department of Labor, however, either such protection was not furnished or it was used so carelessly that it was of comparatively little effect. In the United States there are five large factories making storage batteries, one in Ohio, two in New York, and two in Pennsylvania. A great many smaller plants, employing from 5 to 15 men each, are scattered about the country. The investigation dealt principally with the five large plants. The cases of lead poisoning found in storage-battery work are usually acute, with colic and, in severe cases, encephalopathy, but not paralysis. The severer forms of plumbism are not common. In comparison with Germany and Great Britain the storage-battery industry in this country makes a bad showing. In the largest German factory the rate of lead poisoning is less than 1 per 100 employees, and in Great Britain it is about 3 per 100. In the five largest factories here the rate, based on reports known to be incomplete, is almost 18 per 100. The difference is due to the neglect in the United States of factory sanitation and of personal care of the men employed.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

KALGOORLIE, WESTERN AUSTRALIA

Relief Fund for Miners.—Rain and Prospecting.—Edna May Mine.—Great Boulder Reserves.—Future of the Associated.—Ivanhoe and Horse-Shoe.

The Mine Workers' Relief Fund has now been placed on a working basis with a board of control of five members, consisting of two representing employers and employees, respectively, and one representing the Government. The annual contributions are expected to reach $72,000. The subscription for the first half of February amounted to $2880, so that it looks as if the estimate of revenue is on the conservative side, as, when a canvasser starts work, new members are likely to be enrolled. There is no doubt that the scheme is a good one, and will ensure provision for every worker without any semblance of charity.

Owing to the unprecedented rains of the last four months there is water everywhere, even the so-called salt lakes being real lakes, many of them for the first time since the discovery of Coolgardie (1892). As a consequence there is a good deal of activity in prospecting. The Government and Chamber of Mines are co-operating in supplying camels and tools to any genuine prospectors who apply. Already 50 parties have been equipped, and there are more to follow.

Owing to the great success of the Edna May at Westonia, Melbourne speculators are as excited as during the Bullfinch boom of five years ago. Already a dozen companies have been formed to take up areas within a radius of five miles, which, so far as known, contain neither lodes nor gold. In every case the shares offered are over-subscribed, and almost immediately rise to a premium. The market valuation of the group is $1,500,000, of which the Edna May alone accounts for half. Since its formation in February 1913, this company has produced 45,000 tons of ore, yielding $981,000, of which $428,500 has been distributed in dividends. Three levels only have been opened, at 75, 150, and 225 ft. The main shaft is now down to 300 ft. There is still a good deal of controversy as to whether the lode will persist, or be cut off by granite, as happened in the case of the lode of the adjoining mine, the Greenfinch. Already two floors, or spurs, of granite have been passed through, one 18 in., and the other 8 ft. thick, and whether solid granite intervenes, as in the Greenfinch, remains to be proved. The position is interesting both from a geological and a speculative point of view.

The two eastern lodes in the Great Boulder, at Kalgoorlie, are still being tested by diamond-drilling from the Perseverance workings. Average ore has already been found by trenching on the surface at various points, covering a distance of 1200 ft., and bores have been put in at 1100, 1250, 1450, and 1800 ft. The drill is now operating at 2200 ft. The manager, Richard Hamilton, appears to be sceptical as to the persistence of the lodes, but, judging from the steady rise in the price of the shares, the market takes a different view. Until cross-cutting and driving is started the real value of the discoveries will remain in doubt, as in few cases have diamond-drill results proved trustworthy on the 'Golden Mile.' Reserves in the Great Boulder on December 31, 1914, are estimated as 627,900 short tons, worth $13.62, against 688,900 tons, worth $13.26 a year previously. Since shaft-sinking was stopped, in 1911, 641,800 tons has been milled, giving an average yield of $12.72, equivalent to an extraction of 95.87% of the estimated gold content. During this period the ore reserves have fallen from 782,400 tons, worth $13.26, to 627,900 tons, worth $13.62, or 154,500 tons. This shows that 487,300 tons has been developed in the old levels without reducing the value of the ore, or of the profits. The present reserves are sufficient to keep the mill running three years, but, if ore continues to be found, as in the last three years the life of the mine will be prolonged beyond that period, even if the eastern lodes provide no ore at all.

Since Malcolm Maclaren stated in 1913 that it was useless for the Associated company to look for ore in the bottom,

GEOLOGICAL MAP OF WESTERN AUSTRALIA. THE EDNA MAY MINE IS JUST SOUTH OF THE 'D' IN YILGARN GOLDFIELD.

or calc-schist zone, work has been devoted entirely to the upper levels, and to sinking prospecting shafts. The result, unfortunately, has proved unsatisfactory. The grade of ore now available is too low to be profitable, and the mine is not likely to last much longer. To meet a deficit every month can hardly be expected of any group of shareholders.

The Ivanhoe main shaft in the middle of January was down 3226 ft. Sinking is still in progress. In February the mill treated 18,127 tons of ore yielding $8.14 per ton. The profit was $48,000.——On March 9 the Horse-Shoe main shaft was down 2982 ft. At 2480 ft. No. 4 lode is 8 ft. wide, assaying $8.12 per ton.

The gold yield of the state in January was $2,097,000. Dividends amounted to $509,300. The totals to date are $602,686,000 and $125,771,0000 respectively.

TORONTO, ONTARIO

Changes in Dome Officials. Dividend Talk. Diamond-Drilling. Larger Mill Capacity.—Vipond Affairs.—Smaller Porcupine Properties.—Nickel Mining.

The recent strong advance in price of some of the Cobalt and Porcupine mining shares has served again to draw the attention of the public to these securities. Brokers are doing their best to stimulate this interest and to make capital out of it. The most interesting rise was in the Dome. This jumped from $6 to $14 per share in a few days. This movement immediately followed the announcement that Ambrose Monell had resigned the presidency of the company and was succeeded by J. R. De Lamar. Several other officers and directors also resigned. The new president is one of the best known mining men in the United States, and the market excitement is generally credited to his influence. Apart from this, the impression among brokers and mining men is that in the future some shares will have a more stable market at higher prices than prevailed before the recent advance. Persistent rumors are to the effect that a dividend would shortly be declared at the rate of 10% per annum; but they have been quieted by the semi-official statement that such is not contemplated at present. Recent encouraging developments on No. 4 and 6 levels have been responsible for shareholders thinking this. From the No. 6, 544-ft. level, a horizontal diamond-drill hole passed through 157 ft. of ore assaying $16.48 per ton. This is the greatest width of any such grade of ore that has been found below the 100-ft. level. While it is too early to say what the full extent of this discovery may be, it is considered as being indicative of important developments in the future. It also has stimulated the belief that the grade of the ore in future will be higher than was estimated in last year's report, in which the reserves were given as 3,000,000 tons averaging $3.80. Plans are being prepared to increase the capacity of the mill from 23,000 to 28,000 tons per month, and underground development will have to keep pace. Underground electric haulage will be installed. A large crusher is now being erected on the bottom level. At the present time the company is operating its reserve steam-plant on account of the small supply available from the hydro-electric plants on the Mattagami river, which is low.

The annual report of the Vipond company shows that it is emerging from its difficulties satisfactorily. Liquid assets amount to $41,275. A good profit is being made each month. It is expected that the bonded indebtedness of $65,000 will be paid off within six months. Ore reserves are estimated at 48,300 tons, having a gross value of $430,000. Vipond shares advanced over 30 points in three days. This, however, is supposed to be the result of squeezing the 'shorts,' and the move seems to have succeeded admirably. At 89c., which is the last quotation, the property has a market value of over $700,000, against a net profit of about $125,000 contained in the ore reserves. This is after deducting losses, working costs, and bonded indebtedness.

Several of the smaller properties in Porcupine are receiving more attention. The Apex company is to be reorganized. ——Efforts are also being made to finance the West Dome.—— The Gold Reef has been leased to a new company. It will pay a royalty of 15% of the gross output.——The Schumacher is breaking ground for a new mill. It will use rolls and ball-mills.——The Rea, with only four months' ore reserves, is diamond-drilling.——The Miracle company will increase the capacity of its mill from 40 to 150 tons per day.——The Lally mine, a few miles west of the Hollinger, will do a considerable amount of work this year. A cross-cut on the 100-ft. level has shown about 12 ft. of $5 ore.

The publication during the past few weeks of the annual reports of a number of Cobalt companies emphasizes the fact that the district has passed its best days, and is now declining rapidly. Almost all of these reports show decreased production, ore reserves, and profits. Lower prices were obtained for silver, while higher production costs ruled.

The demand for nickel is such that the Canadian Copper Co., at Copper Cliff, is making every effort to increase production. It is gratifying to note that a large part of the demand is for industrial purposes. Blast-furnace practice has progressed to the stage where it is no longer necessary to use the reverberatories to treat the 'fines.' The large demand for nickel necessitates the installation of a new blast-furnace. At the Creighton mine, a new inclined five-compartment shaft is being sunk. A complete new hoisting and rock-crushing equipment will be erected. A large number of workmen's houses will also be built. It is estimated that the cost of all these improvements will be about $750,000.

NEW YORK

On 'Change.—Alaska Juneau.—Copper.—Amalgamated Copper.—Inspiration.—Flotation Suit.—Lake Copper Costs. —Tin.

After having had the extinguisher placed on the early efforts to make trading capital out of the anticipated allotment of Alaska Juneau shares, the allotment has been finally made. The issue was several times over-subscribed. Open-market quotations have been made this week as high as $16 per share. This enabled a good many of the subscribers to reap a quick and substantial profit. It is fortunate for the mining sharemarket to have a leader of the caliber of Alaska Juneau, especially just at this juncture, when apparently all faces have been turned toward the rising sun of—to use the phrase of the Street—'a primary bull market.' It has been, literally, years since Wall Street has seen anything like the scenes of activity now being enacted. The trend of talk has changed. The old atmosphere is coming back. If those who make up the population within earshot of Trinity's chimes could dictate, there certainly would be no dampening of the current growing enthusiasm. Alaska Juneau, under the conditions outlined, may possibly develop a market behind itself for other issues, so that presently it may be possible once again for a mining property to secure some reasonable support and distribution through the market. This is a consummation much desired. A rather queer situation has developed in arbitrage in mining shares between New York and Salt Lake City. There has been a good deal of booming of the camp of Alta, Utah, of a kind not altogether above criticism; but it has created a considerable public demand. The Salt Lake City brokers are getting the money, much to the disgust of the New York contingent, with the exception of a few with wire connections.

No small part of the strength of the recent market has been in the copper stocks, reinforced by the avidity with which the metal is being absorbed. Prime Lake is quoted at 18c. per pound, at which level it shows no evidence of any curtailment of consumption. Trade gossip is to the effect that enormous sales of electrolytic are being put through at a fraction under 17c. It is hardly necessary to add that mines, smelters, and refineries are all under orders to get back to normal capacity as quick as possible. Whether or not it is a case of making 'hay while the sun shines' is hard to tell. The present insatiable demand for copper is due to requirements for ammunition. The more remote, but equally important, question is, what will be Germany's position when peace is made? Germany was our best customer for copper, and that country's position when the struggle ends will be important as to whether there is immediately to ensue a period of reconstruction or whether there will be a more or less prolonged period of prostration. Should the latter be the case, reliance will have to be placed on the producers so to handle the situation as to prevent the piling up of large stocks.

It is stated that within 30 days some definite plan to dissolve Amalgamated Copper will be announced. What a passing it will be, and what a fund of reminiscence will be uncovered! Rogers, Lawson, Heinze, and 'the days that were, the days that were.' In the meantime the shares have risen on the strength of the announcement of impending dissolution.

Inspiration is getting a great deal of publicity just now. Its career as a producing mine is soon to begin, and it is entirely natural that interest and enthusiasm should increase at this time. As an instance of how rapid this forward march has been, it was stated in a discussion concerning Inspiration recently that only 12 years ago the original owners of Inspiration were trying to sell shares at 10c. each. Now the property has a market value of $22,900,000, not including bonds of $10,500,000. It is to be the second largest single copper producer in the United States. Operating costs at the Inspiration will be interesting to follow. The Miami company has just published its costs for 1914. They were 9.29c. per pound against 10.60c. during 1913. Inspiration will handle much larger tonnages than does Miami, and as the properties are physically one Miami's results may be taken as a close guide for approximate results to be obtained at the Inspiration.

Evidently the suit being heard at Wilmington, Miami *v.* Minerals Separation, is of much greater importance than would appear simply from the record. Technically the Miami is defendant in a suit for the infringement of the Minerals Separation company's patents. As a matter of fact, the Miami is fighting a case in which nearly all of the low-grade milling copper companies are interested. For instance, Anaconda has developed a flotation process which is expected to add 50,000,000 lb. of copper to its annual output. This has hitherto been lost or impounded in the mill tailing. One of the interesting points of the fight of the Minerals Separation to uphold its patents has developed by reason of the fact that the decision of the Supreme Court in the Hyde case, which was adverse to the former, is in direct conflict with the recent decision of the Privy Council in England. This conflict is to be made the basis for a petition for a rehearing in the Supreme Court, on the ground that conflict of the decisions of the two Courts, both of last resort and of equal dignity, has created an intolerable situation, which should be recognized and in some way cured.

One of the interesting developments of the moment in the copper situation is the passing to the head of the list of low-cost producers of one of the Lake mines. The Champion, of the Copper Range group, is producing copper at 6c. per pound. Ahmeek has been the cheapest operated of the copper country, but never got its costs down to so low a figure. The Champion mine is yielding about 30,000,000 lb. of copper per annum.

Arizona Commercial, which has had a long up-hill struggle, is about to become a regular shipper to the Old Dominion smelter.

The tin market has been peculiar. American dealers found themselves unable to secure tin which should have been forthcoming. Investigation revealed the fact that Germany was getting large quantities of tin through certain channels in England. This resulted in England placing such restrictions on tin shipments as to make it difficult to replace stocks. The supply of tin now in the United States is lower than it has ever been, and an unstable and erratic condition has been created. Price of the metal has moved between 45 and 58c. per pound.

Reports of the Chino, Miami, Nevada Consolidated, Ray, and Utah Copper companies have been issued. As usual, they are excellent examples of what annual reports should be. They contain enough information to satisfy all interested. The plans and photographs show what is being done on the surface and underground. Abstracts of the reports will appear in future issues of the *Press*.

VICTOR, COLORADO

Golden Cycle Mill.—Cresson.—Ajax Mill Closed.—Drainage Adit.—Portland Mine.—Stratton's.—Vindicator Mill.

The Golden Cycle Mining & Reduction Co. has made its appearance on the market, and shares are now offered for sale. Quotations on April 17 were $1.88½ and $1.90. In the recent merger the Vindicator Gold Mining Co. acquired the Golden Cycle mine. It paid $1,500,000. This settled the Christmas lawsuit against the Golden Cycle, in which the Vindicator claimed $1,000,000 for ore unlawfully extracted. The balance of the Golden Cycle holdings, the mill at Colorado Springs, and the coal mines there, together with various properties in the Cripple Creek district known as the United Gold Mines Co., are merged into what is now known as The Golden Cycle Mining & Reduction Co. The new company is capitalized at 1,500,000 shares of a par value of $1. The directors are A. E. Carlton, E. P. Shove, H. G. McGarry, Irving T. Snyder, Richard Roelofs, Spencer Penrose, and J. F. Burns. They are all well known in Colorado, especially in the district. Dividends of 24c. per year are predicted. In the prospectus some interesting figures are given of the operation of the mill:

	Ore treated. Tons.	Bullion recovered. Value.
January	27,194	$ 571,063
February	27,056	721,799
March	29,000	1,305,000

The average value of the ore treated in 1914 was $19.16, compared with $16.28 in 1913. Ore treated from 1908 to April 1, 1915, totaled 2,440,770 tons. Bullion extracted amounted to $43,739,385.

The development made on the No. 12 level of the Cresson in December last has yielded a gross value of $1,500,000 to date. A good deal more is in sight.

The Ajax mill stopped on April 10. Apparently this was due to lack of ore. This mill started operations in November 1911. The Clancy process was used. The plant had a checkered career. It was altered and re-altered a number of times until, at the close, it was conforming to standard practice of concentrating and cyaniding. It is reported that the shaft of the Ajax mine is to be sunk.

Bids are now held by J. F. Burns for the extension of the Roosevelt drainage adit from its present heading, approximately under the Gold Dollar shaft, to the Elkton shaft. The new hoist at the El Paso main shaft, replacing the one destroyed by fire some time ago, is now at work. Air will be supplied and waste hoisted through this shaft. The adit is at present discharging about 12,000 gal. of water per minute. Water-level on Battle mountain is 8473.29 ft. above sea-level, making a total recession to date of 391.21 feet.

Construction of the Caley mill at the Jerry Johnson mine, on Ironclad hill, is rapidly nearing completion. This will be a 100-ton cyanide mill, suitable for the oxidized ore which occurs in that property.

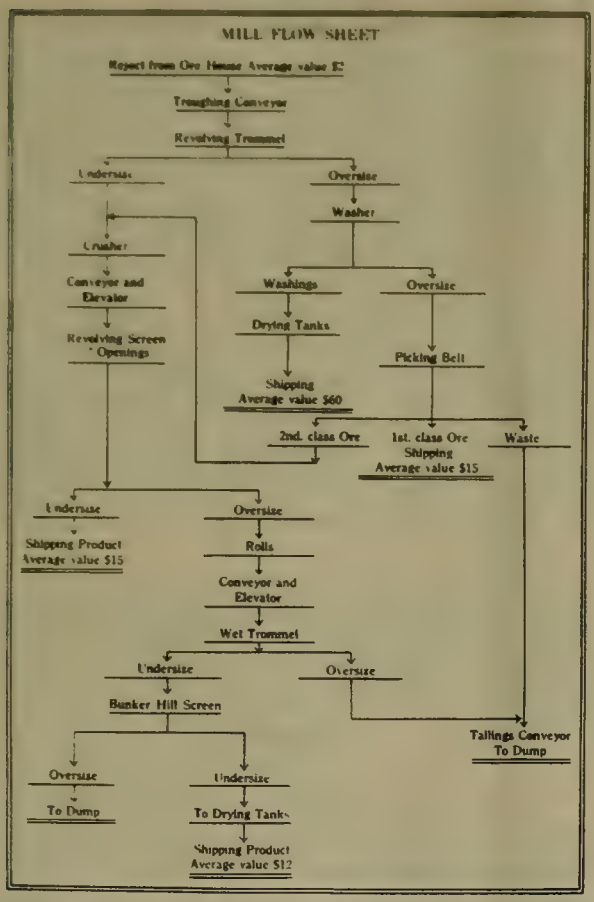
The 1750-ft. level of the Portland mine still continues to show rich ore. Development proceeds vigorously.

At Stratton's Independence the Mill vein system has produced well during the past year. It is now better than ever on the 500-ft. level, though a distance of 500 ft. into the granite. On this level, 300 ft. south of the shaft, the heading shows an eight-inch streak of manganese-colored mud assaying over $600 per ton. In the stopes, over 2-oz. ore is broken, and heavy shipments are being made. The dump at the mill is getting small. Probably not more than six months more will be required to clean it up. After that the mine will have to keep the mill in operation if it can.

The Vindicator screening and washing mill is working steadily. It deals with about 300 tons per day, and returns

a fair profit. The mine is shipping a good tonnage of $60 ore. With its additional area in the Golden Cycle, it must be regarded as the big mine of the district. No changes in the casting system have been made so far.

A 'Greater Cripple Creek' edition has been published by



MILL AT VINDICATOR MINE, CRIPPLE CREEK, SAVING $12 TO $60 PRODUCTS FROM ORE-HOUSE WASTE.

The Daily Mining and Financial Record of Denver. It consists of 20 pages with illustrations, covering all phases of the Cripple Creek district.

BOSTON

THOMPSON, TOWLE & CO.—STOCK EXCHANGE AND CURB.—THOMAS W. LAWSON.—SOUTHWESTERN MIAMI.—NEVADA-DOUGLAS.—LAKE SUPERIOR COPPER.—FORTUNA MINES.—BOSTON & MONTANA.

The most important change which has taken place in Stock Exchange circles here since the first of the year has been the long-expected dissolution of Thompson, Towle & Co. W. B. Thompson, the head of the firm, retires from the brokerage business, probably on account of his official connection in New York with the Federal Reserve Bank. George N. Towle becomes a special partner with Joseph N. Lovell, formerly a member of Thompson, Towle & Co., who has formed a new firm under the name of Lovell & Co. W. F. Pillsbury becomes a general partner. W. F. Bartholomew, for 17 years one of the chief associates of C. W. Barron on the *Boston News Bureau* and for five years a member of Thompson, Towle & Co., has entered the firm of Tucker, Hayes & Co., the new name of the company having become Tucker, Hayes & Bartholomew.

It has been more than five years since the Boston and New York stock exchanges have transacted the business they have recently. The activity, which is both professional and of a public character, is putting new life into financial circles here. The 'coppers,' 'zincs,' and 'golds' are all doing well here. The usual thing is for brokers to assemble at the ring of the gong in the morning, expecting to see an overbought market, only to witness another flood of buying orders. It is really a remarkable situation, which bids more or less defiance to war conditions in Europe, showing that the American people have at last turned themselves loose, and have determined to once more do business. It is nothing unusual for the Stock Exchange to turn over from 60,000 to 75,000 shares in a session. The curb total is from 35,000 to 40,000 shares. Several new issues have appeared on the Curb since the first of the month, among them being Alaska Juneau, Alta, Emma, and Calumet & Montana. The active Curb list is more than twice as long as it was a few months ago. The change which has taken place in the share-markets is so apparent that many people who have held aloof from trading are at last won over, conceding that undoubtedly a genuine revival of interest has taken place.

The absence of Thomas W. Lawson from market activity is freely commented on here. There has been a little doubt as to his whereabouts. Some people say he is still enjoying ranch life in Oregon, while others say he is back in seclusion at his Dreamwold estate. A recent newspaper article suggested that he was abroad. Rumor has also been busy to the effect that he is a sick man. At any rate, nothing is happening in the market which can be traced to Mr. Lawson, and his newspaper puffs and Street 'tissues' are conspicuous for their absence. About a month ago Mr. Lawson lost by death a younger brother, John L. Lawson.

The return of Miami to dividend payments, and the activity of Inspiration Consolidated, caused Southwestern Miami to re-appear in the trading column of the Boston Curb recently. It has been active there from time to time. The prospects of this property appear to lie in its profitable absorption by the Miami or Inspiration interests.

The revival of interest in Lake Superior coppers is resulting in a number of Boston brokers and financial writers visiting that region to note the changes which have taken place since the strike was settled and the mines resumed operations at full capacity. The labor situation is better than it has been for a number of years. James F. Sheldon, the financial editor of the *Journal*, is now in the copper country writing-up the situation. Eugene Cronin, of Hornblower & Weeks, is also on a trip there. Several of the officials of various Lake companies, and those close to the managements, have also recently visited the district. It is said that the mines are now producing 850,000 lb. per day, valued at $125,000.

Considerable disappointment has developed here over the reaction in the stock of the Fortuna Mines Corporation of Yuma Arizona, which was listed for trading on the Boston Curb early in February, and had for a while a sensational market run. The stock was manipulated to $3 per share, and then allowed to slump to $1.25. Since then it has failed to regain its loss. The slump was coincident with the announcement that Charles D. Taylor, at one time a mine operator in Goldfield, had bought the controlling interest in the Fortuna property, succeeding Frank B. Keever as manager. Taylor is a cousin of Todd C. Woodworth, consulting engineer of the Fortuna company, and it is believed that from now on the control of the company will be in the hands of Woodworth and Taylor, supplanting Keever. It is thought in Boston that a lot of shares of the company are held on the Pacific coast, and fear of this stock coming on the market is said to have depressed the price.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Philip S. Smith and A. G. Maddren, of the U. S. Geological Survey, examined the quicksilver deposits of the Kuskokwim basin in the summer of 1914, and a bulletin has been issued describing the deposits. The Parks and Kolmakof deposits are close to the Kuskokwim river, on which ocean-going steamers can ascend within 150 miles of the farthest west prospect. Small timber suitable for mine use is fairly plentiful in the better-drained lowland areas. The Parks claim has been opened by a cross-cut adit 200 ft. long. A good tonnage of cinnabar has been found, but development has not been extended far enough to block out any body of it. The country-rock consists of shales and sandstones, cut by dikes of granitic intrusive rock. In the oxidized parts of the deposit the cinnabar is almost unrecognizable, being coated with iron oxide. The Kolmakof ore has been known for over 25 years. A few shallow pits have been sunk. The country is similar to that at the Parks. Cinnabar is abundant in quartz stringers and lenses, the latter being 6 in. wide and 24 in. long. Cinnabar has also been found 2½ miles northwest of the Parks and near Iditarod. Proper prospecting is essential, and the deposits warrant this being done.

Juneau

New York and Seattle people, headed by Makeever Bros., of New York, on April 8 completed the purchase of the old Nelson-Lott property. This adjoins the Gastineau mine near Juneau. The new owners will spend $225,000 this year in development. A. B. Dodd, mining engineer for Makeever Bros., has gone north to start work. The new corporation, which has taken over the mining property, has a capital of $1,000,000, and will be known as the Alaska Gold-Belt Company.

Ketchikan

(Special Correspondence.)—A petition has been sent to the Territorial Legislature at Juneau asking that a memorial be sent to Congress for a milling and smelting plant of 200-ton daily capacity in the Ketchikan district, to be operated under direction of the U. S. Bureau of Mines. Some of the benefits to be derived from such a plant would be the recovery of the iron that goes to waste in smelting magnetite copper ores, large bodies of which exist in this district. It will also benefit the prospector and small mine-owner in many ways, and will give reliable data on which to base future estimates as to the advisability of installing a larger plant or plants by private capital.

The Granby company has made its first shipment of ore from the Mamie mine, consisting of 1000 tons, to its smelter at Anyox, British Columbia. The same company is repairing the dock at Karta bay, in preparation for shipping ore from the It and Dean mines.

Last month's shipment from the Rush and Brown mine was 250 tons of fair-grade ore. The amount to be shipped this month will be about 1000 tons.——The Goodroe mine has just been examined by W. L. Polson. His report is said to be favorable. The mine probably will be re-opened shortly. Platinum was detected. Concentration tests made by Polson showed that the amount saved by this method may increase the value of the output. Edward Brown, assayer at Ketchikan, has detected platinum in a number of samples taken from this district.

Ketchikan, April 12.

Nome

The annual all-Alaska sweepstakes dog-race from Nome to Candle and back, 412 miles, was finished on April 17. Five teams entered. The winner was Leonard Seppala with 16 Siberian wolf dogs. The time was 78 hours 44 minutes 37 seconds.

ARIZONA

Gila County

The Old Dominion smelter at Globe was started again last week, having been closed since March 16. The plant was stopped on account of the mine being flooded. The present quantity of ore being mined is 250 tons per day. The normal output is 800 tons.

The report of the Miami Copper Co. for 1914 shows that ore reserves are as follows: high-grade sulphide, 19,500,000 tons at 2.40%; low-grade sulphide, 75,000,000 tons at 1.21%;

FAIRBANKS DISTRICT IN APRIL.

total 36,500,000 tons at 1.85%. Not included in the above is 6,000,000 tons partly developed mixed sulphide and oxide ore containing about 2% copper. The output was 1,096,633 tons of ore yielding 33,296,010 lb. copper.

Mohave County

(Special Correspondence.)—The west drift from the winze sunk 125 ft. below the 950-ft level in the Tom Reed mine has been extended 100 ft. in ore. The vein is from 6 to 10 ft. wide, the ore broken being sent direct to the mill. Stoping is to begin in a short time. Where opened at 1075 ft., the orebody shows a marked change in formation to that obtaining on the levels above. No water is flowing in the bottom level, although above it requires continuous pumping, according to the manager, S. S. Jones.——The United Eastern company's shaft is down 135 ft. A hoist is to be erected. Then the shaft will be sunk to 400 feet.

Oatman, April 12.

ARKANSAS

The North Arkansas mining district is having a boom. More ore has been shipped this year than in any previous full year. The district practically adjoins the Missouri-Kansas-Oklahoma region. John T. Fuller, state geologist, after an examination of the zinc and lead mines in Boone, Marion, Newton, and Searcy counties, thinks that success will only be obtained by means of a number of small properties.

CALIFORNIA

Amador County

The Plymouth Consolidated company's preliminary report for March is as follows: Ore crushed, 11,000 tons; value of gold, $56,814; working expenses, $23,764; development charge, $9231; and surplus, $23,819. During 1914, August to December, the output was 44,773 tons of ore averaging $4.35 per ton. The residue assayed 57c. per ton. Recovery was 88.24%. Costs averaged $3.26 per ton. The operating profit was $33,600. This was reduced to $980 with development and other capital charges.

Butte County

Permission has been asked by L. Gardella, well known in Oroville, to be allowed to dredge certain areas within the city limits, and surrounded by improved property. This is against the regulations, but it is hoped that the request will be granted.

Calaveras County

On April 5 the Calaveras Copper Co., at Copperopolis, shipped 30 tons of 9.87% ore. Net proceeds were $545. On the same day lessees received $1417 from a car of ore which averaged 17.6%. Some concentrate has to be settled for. Experiments show that when the mill is equipped with a flotation plant, a higher recovery will be made than originally anticipated. It is stated that monthly earnings in a few months will be about $40,000 per month.——San Andreas people are re-opening the Ford quartz mine. It has been closed for 15 years.

Inyo County

Production of the Cerro Gordo mines in 1914 was as follows: Ore, 4278 tons; gold, 312 oz.; silver, 303,086 oz.; lead, 1,195,000 lb.; and copper, 283,068 lb. Mining of zinc ore has been resumed. Reconstruction of the aerial tramway to Keeler is being done by A. Leschen & Sons, of St. Louis. When completed, the two sections will be 29,118 ft. long.

Thirty men are now employed at the Bishop Creek mine. The workings were unwatered in three days. Stopes are being opened. The mill should be producing bullion in May.

Kings County

In the Kings Quicksilver Mining Co.'s property, 18 miles southeast of Coalinga, is showing an extensive orebody on No. 1 level. A Scott furnace is treating 10 to 12 tons per 24 hours. A 6-ft. Huntington mill and concentrators are being erected. This plant will be ready about May 15. A. A. Lewis is manager for the Canadian controlling interests.

Nevada County

A new head-frame is being erected at the Polar Star mine, which adjoins the North Star on the west. At 300 ft. in the shaft there is 4 ft. of ore.——An abstract of the annual report of the North Star Mines Co. appears on another page of this issue.

Shasta County

Work is to be resumed at the Shasta Belmont copper mine in May. The property is between Copper City and Heroult. Nevada people are interested.

Tuolumne County

Los Angeles people have acquired a large area of gravel northwest of Shaw's Flat. The Buckeye mine is nearby. A large quantity of gold has been extracted from the district in the past.——The Atlas mine is being unwatered, and the 10-stamp mill is to be started soon.

COLORADO

Dolores County

(Special Correspondence.)—An important gold discovery was made in the Pro Patria adit of the Rico Consolidated Mines Co., about two weeks ago. Two lessees had been working in the adit for some time with poor results, and had asked merchants in town to extend their credit. This was refused. The miners decided to have assayed a peculiar-looking ore they had been working on for about a week. Metallics were visible on breaking the sample, and it returned $15,000 per ton in gold. The lessees had thrown nearly three narrow-gauge cars of this ore over the dump. This they shipped.

Jesse Knight and others of Salt Lake City, Utah, are making regular shipments of silver-lead and zinc ores from the Rico Wellington.

Rico, April 15.

Lake County (Leadville)

Great interest is being taken in Leadville in the arrival of the pumps for the Down Town pumping scheme. They were made by the Providence Engineering Works of Providence, Rhode Island. H. S. Arnold has arrived to supervise installation.——The new zinc oxide plant is in operation again.——Reports from the Twin Lakes and Lackawanna districts continue to be favorable.——The report of the Iron Silver Mining Co. appears on another page of this issue.

Teller County (Cripple Creek)

Increased leasing is to be done at the El Paso mine. Lower royalties will be charged so as to induce lessees to take blocks of ground. The new plant, in place of that burned, is in operation.——Since the new compressor was started at the Dexter mine on Bull hill, ore shipments have shown an increase. Lessees are doing fairly well.——In February Stratton's Independence made a net profit of $5000. There was 4788 tons of $6.76 ore mined. The mill treated 9668 tons of low-grade mine and dump ore.

IDAHO

This state has a large exhibit of minerals at the Exposition. In a future issue of the *Press* it will be described.

Lemhi County

(Special Correspondence.)—After several months' idleness the Bohannon dredge resumed work with three 8-hr. shifts last week.——The Musgrove mine and mill, west of Leesburg, was closed in January on account of the water freezing, but re-started on March 15. Good profits were made in 1914, and there is plenty of ore ready for treatment.——The Strahan mine and mill has been leased by John M. South.——Work has been resumed on the Gold Dust claim north of Leesburg.

Leesburg, April 8.

SHOSHONE COUNTY (COEUR D'ALENE)

The Hecla Mining Co., of Burke, reports that during 1914 its output was as follows: ore mined, 123,857 tons; ore and concentrate shipped, 20,151 tons; lead content, 18,957,823 lb.; silver, 509,200 oz.; operating profit, $246,551; and dividends, $220,000. Lower prices for metals affected the revenue. The shoot at 1600 ft. is producing rich ore. There are 170 men employed, in charge of James F. McCarthy, the general manager.

The Federal company's Morning mine has resumed work after several weeks' shut-down. Over 400 men are employed. ——A cross-cut from No. 4 adit of the Interstate-Callahan company's Callahan claim has passed through 10 ft. of 25 to 35% zinc ore. This shoot is 350 ft. under the original Callahan workings.——From 10 to 36 in. of rich antimony ore is being opened on Pine creek by the Antimony-Silver Mining Company.

MISSOURI

JASPER COUNTY

Forty acres of the Schifferdecker land, three miles from Joplin, was sold recently for $40,000. The ground has been prospected, ore occurring at 190 ft. A mill will be erected. ——Motor-driven pumps are draining the 770-acre tract south of Carterville, and the eastern part should be dry by the first week of May. The Zinc Corporation has this ground under lease.——A 300-ton mill has started work in the Prosperity portion of the Webb City-Carterville district. Ore is mined at from 190 to 210 feet.

Joplin men have organized the Joplin Ore & Smelting Co., with a capital of $100,000, to acquire the North smelters at Pittsburg, Kansas. Oronogo Circle people are largely interested. The plant has been idle for 18 years. It will require considerable expenditure for improvements.

MONTANA

SILVERBOW COUNTY

It is estimated that by the beginning of May the following men will be employed in the Butte district: Anaconda, 8000; Butte & Superior, 1100; North Butte, 600; East Butte, 500; Elm Orlu and Timber Butte, 500; and other mines, 800; a total of 11,500. The payroll will be about $1,150,000 per month. Employed in other work will be 3000 receiving $350,000 per month. The total number employed will be 14,500, receiving $1,500,000.

MINES AT BUTTE.

The Mountain Con. mine of the Anaconda group was reopened last week. There will be about 350 men employed, and the output over 600 tons per day.

During the shut-down of some of its mines, the Anaconda company accomplished a lot of shaft-sinking and development on the lower levels. The shaft of the High Ore mine has been sunk from the 3220 to the 3400-ft. level; Diamond, from 2960 to 3080 ft.; Stewart, from 2500 to 2800 ft.; Mountain Con., 2530 to 2750 ft.; No. 2 shaft of the Leonard, from 2069 to 2241 ft. Nearly 100 ft. has been added to the Belmont, which is down 2100 ft.; and the West Gray Rock from 1622 to 1770 ft. The depths of other shafts of the Anaconda company are: Anaconda, 2660; Neversweat, 2450; St. Lawrence, 2550; East Gray Rock, 1639; Original, 2764; Badger State, 2054; Moose, 500; West Colusa, 2039; East Colusa, 770; Leonard No. 1, 2154; Tramway, 2350; Silverbow, 1003; Parrot, 2150; Moonlight, 1725; Pennsylvania, 2237; Mountain View, 2306; Modoc, 2525; Buffalo, 1500; and Greenleaf, 1030 feet.

NEVADA

ESMERALDA COUNTY

Rich ore continues to be opened in the shale, and below the contact, at 1017 ft. in the Jumbo Extension.

HUMBOLDT COUNTY

A number of well known mining men have visited the new Willard district. Gold has been found in four groups of claims. Several leases have been let. About 75 people are living in the township.

A 100-ton mill is to be erected at Kennedy, 60 miles from Winnemucca. It will treat ores from the Virginia, Ida. and Hazel Belle claims of the Roylance Reduction Company.

LINCOLN COUNTY

Shipments of zinc ore from the Amalgamated Pioche have been curtailed, as the smelters do not require more for the present.

NYE COUNTY

Eight mines at Tonopah produced 10,760 tons of ore, worth $219,640, during the week ended April 17.——The following are March yields: Belmont, 16,375 tons, for 3169 oz. gold and 290,897 oz. silver, with a profit of $88,520 (the annual report of this company is to hand, and will appear in another issue of this journal); Jim Butler, profit of $25,167; and Tonopah Mining, 11,945 tons for 221,640 oz. bullion, and a profit of $70,560.

WHITE PINE COUNTY

(Special Correspondence.)—The Nevada Consolidated company is again operating full time, and the mill is treating between 10,000 and 11,000 tons of ore per day. It is reported that the company has an order to supply 25,000,000 lb. of copper. The Ruth mine is being prepared for underground work. This property contains many million tons of 2.1% copper ore. During the curtailment of operations since last August, the company learned many methods of economy, and it is doubtful whether as many men will be employed as formerly to mine and treat the same tonnage. There are plenty of men out of work at present.

Ely, April 5.

During March 1460 men were employed by the Nevada Consolidated company. At Copper Flat there were two disabling accidents, resulting in the loss of 11 or 12 days' time; two minor injuries at the mill, and six at the smelter, where four men lost a total of 13 days, one 23 days, and another several weeks.

The Consolidated Copper Mines Co. is preparing to resume

ore extraction at the Ora claim. This is at the entrance to the Nevada Consolidated's Liberty pit. One steam-shovel will be employed, and the latter company will mine and treat 24,000 tons per month for the controlling company. E. F. Gray is general manager.

OREGON

Baker County

A syndicate of California dredging people is examining ground near Clark's creek, below Bridgeport. F. J. Estep is in charge with eight men. Drilling is to be started as soon as possible.

TENNESSEE

Polk County

The report of the Tennessee Copper Co. for 1914 shows that ore reserves are estimated at 4,010,661 tons, exclusive of the Eureka orebody. The output of metal was 12,871,113 lb., a little less than in 1913. Acid production totaled 210,163 tons.

UTAH

On account of the metal market and the large quantities on hand, smelters are not buying any zinc ores from Utah mines at present. The exceptions to this are a few lots of carbonate ore and sulphide ore contracts.

Beaver County

The Four-Mile Springs gold district is attracting some attention just now. It is not far from Fortuna.

Juab County

Ore shipments from the Tintic district last week totaled 127 cars.——Lessees in the Yankee Consolidated are shipping up to 41% zinc ore. One car yielded $1435 net. Lead-silver ore is also being extracted.——The Knight-Christensen mill is to be rebuilt. Some of the steel buildings at the Tintic smelter will be used.——A winze is being sunk below 1700 ft. in the Eagle & Blue Bell. It is in ore all the way. An electric hoist, costing $25,000, is to replace the old steam-engine.——Four cars of silicious ore are being shipped daily from the Sioux dump at Mammoth to the A. S. & R. smelter at Garfield.

The Knight-Christensen mill at Silver City was destroyed by fire on April 4, damages amounting to about $75,000. The plant was a useful one for the Tintic district, and was treating 100 tons daily of Iron Blossom ore at the time of the fire, and the Traylor Engineering & Manufacturing Co. was installing additional machinery.

The annual report of the May Day Mining & Milling Co. for the year ended March 31, 1915, shows that receipts from lead and zinc ore amounted to $106,614. Expenses totaled $84,959. Dividends paid were $40,000, and the year ended with a cash balance of $14,778, against $21,656 at the beginning of the term. Recent development has shown some high-grade silver-lead ore, according to the general manager, J. C. Dick. Eleven sets of lessees are at work.

Salt Lake County

The Alta Consolidated Mining Co. was organized at Salt Lake City last week with a capital of 1,000,000 shares at 25c. each. Its purpose is to drive an adit along the quartzite-limestone contact in the Big Cottonwood district, to cut several veins which intersect the contact. The Wasatch mine will also be opened 1400 ft. below its present workings. A Karns tunneling machine will be tried in the adit.——A 75-stoping drill was carried by two miners from the American Flag mine at Park City to the Alta adit in the Big Cottonwood cañon. The distance is about 17 miles, and the ground was covered with deep snow.

Weber County

Molybdenite has been found in the Southern Pacific Gold & Copper Mining & Milling Co.'s mine, eight miles north of Ogden. J. W. Burnham is manager.

CANADA

British Columbia

In *Bulletin* No. 2, 1915, of 24 pages with illustrations, of the B. C. Bureau of Mines, W. M. Brewer discusses the mineral resources of the Atlin mining division. Mining operations in 1914 were confined almost entirely to the creeks that have been regular producers of placer gold since 1899. Save on O'Donnel river and Spruce creek, all work was done by hydraulic methods and by corporations. It would seem that dredges ought to be successful in certain parts of the district, especially near the head of Spruce creek, on Slate creek, and between the headwaters of that creek and the O'Donnel river, as well as bars on that river. This area is not suitable for sluicing. Considerable detail is given regarding the O'Donnel river, Fourth of July creek, Taku arm, and Rainy hollow properties.

During March the Rambler-Cariboo company at Three Forks shipped 10 cars of lead-zinc concentrate, and silver-lead ore. The net yield was $1500 per car. The new ore-shoot at 900 ft. is high in silver and lead.

Ontario

Thirteen mines shipped a total of 1348 tons of ore from Cobalt during March.

The report of the Nipissing Mines Co. for 1914 states that the output of silver was 4,689,333 oz. The average price received was 55.36c. per ounce. Cost of production was 19.8c. Dividends amounted to $1,235,000. The previous surplus was $1,259,061, while that at the end of 1914 was $1,602,776. Ore reserves are estimated to contain over 10,000,000 oz., an increase of 500,000 ounces.

The McKinley-Darragh-Savage Mines Co.'s report for 1914 shows that 45,098 tons of ore yielded 1,396,540 oz. of silver. The profit was $307,652. Dividends paid amounted to $337,154. Ore reserves are estimated to contain 2,132,120 ounces.

In 1914 the Beaver mine produced 908,000 oz. of silver. Of this, 390,000 oz. was sold.

According to the chief inspector of mines of this province, T. F. Sutherland, there were 58 fatalities in all mines, quarries, and metallurgical works in 1914. There were 445 injured. A peculiarity is that most of the fatal accidents occurred in the first half of the year.

In March the Dome mill treated 23,220 tons of ore, yielding $4.22 per ton. This is the highest average in four months.

The power situation at Cobalt is improving. The supply at present is about 80% of normal. By the end of April the Northern Ontario Light & Power Co. expects to be able to supply all demands. Warm rains will melt the snow and ice on the company's territory.

In March the Nipissing high and low-grade mills treated 93 and 5382 tons of ore respectively. This yielded $104,812 and $64,267, a total of $169,079. Bullion shipped was only worth $27,308. Mine development was satisfactory.

Yukon

A telegram from Dawson states that on April 18 the Yukon river ice was breaking up. This is the earliest in its history. The river is already open from White Horse, the head of navigation, to Lake Labarge, 16 days earlier than last year. The ice on Labarge is dangerous to cross.

KOREA

The Seoul Mining Co., operating the Suan concession in Whang Hai province, reports the following results for March: Total recovery from bullion and concentrate, $82,750; operating expenditure, $25,000; and net earnings, $57,750.

The Oriental Consolidated output in March totaled $145,365. In January, 210 stamps crushed 24,080 tons of ore, and from all processes $136,554 was recovered. The profit was $54,277, of which $21,249 was spent in development and improvements. In February there was 20,795 tons treated yielding $125,152. The Maibong tube-mill plant recovery was 72%,

and Taracol cyanide plant 76%. Transport of supplies was interrupted by an epidemic among the cattle.

MEXICO

Chihuahua

A new issue of paper money is to be made at Chihuahua to replace all previous Villa circulation. The new currency will be printed in New York.

Sonora

At its various mines the Cananea Consolidated Copper Co. is employing about 400 men. They are attending to pumping and other necessary work. The resumption of ore extraction is indefinite.

Up to April 14 the Moctezuma Copper Co. had forwarded 210 cars of concentrate from Nacozari to Douglas, Arizona. A large tonnage remains at the mill. This results from the serious interruption to traffic caused by the revolution. Freight and passengers are also being moved.

PHILIPPINE ISLANDS

The mineral resources of the Philippine Islands for the year 1913 are discussed in a recent bulletin issued by the Division of Mines of the Bureau of Science at Manila. The publication covers 71 pages, and is accompanied by a map and illustrations. A review of the year is covered by Warren D. Smith; the Paracale district, by F. T. Eddingfield; the Araroy district, Masbate, by Warren D. Smith; other mineral districts, including Baguio, by F. T. Eddingfield; the Bulacan iron-ore resources, by Wallace E. Pratt; coal mining, by Wallace E. Pratt; Philippine production of non-metals, by Wallace E. Pratt; gold dredging, by William Kane; mine exploitation and the causes of some mine failures in the Philippines, by F. T. Eddingfield; and a preliminary check list of Philippine minerals, by Warren D. Smith, F. T. Eddingfield, and Paul R. Fanning. The total mineral production was worth ₱3,944,581, of which ₱1,736,724 was from gold.

According to *The News of Baguio*, the present season shows a general awakening in the Benguet mining field. Prospectors are busy. More inquiries are being made from the outside.——At the Benguet Consolidated, C. M. Eye reports that a drainage adit is being driven 500 ft., at a depth of 100 ft. below the main workings. It is in over 200 ft., the monthly advance being nearly 70 ft. A new working adit is being driven 250 ft. A 10-stamp mill, with Dorr classifier, 6 by 10-ft. tube-mill, thickener, agitators, and the continuous counter-current decantation system is being erected. A hydro-electric plant, including Pelton-Doble and General Electric machinery, is being constructed about 2000 ft. below the mill. The 14, 16, and 18-in. pipe-line is 6000 ft. long.——After a varied career, the Headwaters mine is producing about 100 oz. gold per week. L. O. Hibberd is operating the property, in spite of previous reverses by other owners.——The Camote mine has three stamps, which produce about 60 oz. per month. ——It is probable that small mills will be erected at the Bua, Acupan, and Antamok.

THE NEW MALAGUIT DREDGE, PHILIPPINE ISLANDS.

PERSONAL

Frank G. Manley is in San Francisco.

L. D. Ricketts is at Warren, Arizona.

Arthur L. Pearse is at the Palace hotel.

Orville R. Whitaker is in northern Mexico.

Leroy Anderson is here from Jerome, Arizona.

William Truran has returned from Elko, Nevada.

John S. Eastwood will visit Alaska in the near future.

Reiji Kanda will spend three months in Burma this season.

C. M. Weld has moved his office to 60 Broadway, New York.

H. P. Henderson is also to be found at 60 Broadway, New York.

Frank H. Probert has returned to San Francisco from New York.

Louis S. Noble and Harry G. Palsgrove are in southern Arizona.

H. Foster Bain sailed from New York by the *St. Louis* on April 17.

Thomas H. Leggett left Los Angeles for New York on April 20.

James W. Abbott, of Los Angeles, was in San Francisco this week.

F. J. Siebert, of Goldfield, is retained as a geological expert in the Tonopah litigation.

J. J. Flannery, president of the American Vanadium Co., is visiting the Exposition.

H. C. Wilmot, manager for the Syndicate mine, in the Philippines, is spending a holiday in California.

F. A. Voorhees, metallurgist at the Commonwealth mine, Pearce, Arizona, is in San Francisco visiting the Exposition.

Schools and Societies

The University of Idaho has lost its president, M. A. Brannon, who resigned on account of reduction in salary.

The Association of Mine Managers of the Transvaal held its annual meeting in Johannesburg during the third week of February. Palmer Carter is president.

The Montana Society of Engineers held its annual meeting in Butte on April 9 and 10. Several papers were read and visits made to mine hoists and zinc mills.

The University of Utah affairs are to be investigated by a committee of 25 representative citizens, according to a decision of the alumni association of that institution.

The South African Institute of Electrical Engineers held its annual meeting in Johannesburg in February. *The South African Mining Journal* published a special supplement for the occasion.

The San Francisco branch of the A. I. M. E. held its monthly meeting on April 13. The paper of the evening was an abstract, prepared and read by E. A. Hersam, of the monograph on 'Electrolytic Precipitation' by the late Samuel B. Christy of the University of California.

The Colorado branch of the A. I. M. E. held a meeting in the new home of the Colorado Scientific Society on April 9. An illustrated lecture on 'Methods and Processes of Pure Iron Manufacture' was given by Howard See of the research department of the American Rolling Mill Company.

The twenty-fourth annual report of the Council of the Institution of Mining and Metallurgy contains the following information: Membership at end of 1914, 2492; increase over 1913, 120; revenue, £5090; and expenditure, £4935. The new president is Sir Thomas Kirke Rose of the Royal Mint, London.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets

Metal Prices

San Francisco, April 22

Antimony	25 —25¾
Electrolytic copper	18 —18¼
Pig lead	4.45— 5.45
Quicksilver (flask)	$80.00
Spelter	10¾—11
Tin	45 —46½
Zinc-dust, 100-kg. zinc-lined cases	16

A useful and instructive chart has been prepared by 'The Steel and Metal Digest' of New York, showing daily price fluctuations in copper, tin, lead, and spelter, from July 1, 1914, to March 31, 1915. The great rise in tin and spelter is a prominent feature

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, April 22. Copper is strong, and higher prices are probable; lead is steady; spelter is excited.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Apr. 15	50.00	Mch. 10	49.81

There is little change in the silver market. About 50,000 oz. was shipped from San Francisco to the Orient on April 17. The total sent from Cobalt during the week ended April 10 was 360,193 oz. According to the report of the Tonopah Belmont company, on February 28, 1915, it had 1,646,099 oz. stored in San Francisco. There must be other large stocks held by heavy producers in the United States and Canada, and on a rise in price the market is sure to be flooded. Up to April 1 the metal exported from London to India was about 3,500,000 oz. less than in the same period of 1914. Buying from India has been irregular, hence erratic price movements. A shortage of silver coin exists in Egypt. Natives are hoarding it.

COPPER

Prices of electrolytic in New York, in cents per pound.

Exports during the week ended April 17 were worth $909,000, equal to about 5,680,000 lb. In the week ended April 3 they amounted to 10,623,248 lb., valued at $1,568,787. Of this quantity 6,242,436 lb. went to England, 2,713,523 lb. to France, 784,796 lb. to Italy, and 331,157 lb. to Holland. Stocks in England and France on March 31 totaled 17,858 tons. On February 27 they were 21,852 tons. Lake copper has been sold up to 20c. per pound. The Calumet & Hecla company has raised wages of all employees 10%. About 8000 men are affected.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending

May	33.29	....	Nov.	33.51	....
June	30.72	....	Dec.	33.60	....

The tin market has been erratic, and on April 21 quotations varied between 40 and 50c. per pound. A good quantity of metal recently arrived at San Francisco from the Straits. Prices of tin-plate in the United States and England have risen owing to the rise in price of tin and uncertainty of supplies. On March 23 the American price was $3.35 per box of 100 lb., and in England, on March 19, $3.89 to $4.02 per box of 108 pounds.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending

At Joplin, Missouri, zinc-ore prices showed no marked advance last week, but the market has a better tone, and producers have no trouble in selling ore for $54 to $60 per ton, basis of 60% metal. The highest price was $63. A large deal was made on April 16, when W. A. Rhea, of the Mont B mine, sold 1800 tons of lead and zinc ores for approximately $95,000 to the Edgar Zinc Company.

BOOK REVIEWS

PETROLEUM INDUSTRY OF CALIFORNIA. By R. P. McLaughlin, assisted by C. A. Waring. *Bulletin* 69 of the California State Mining Bureau. P. 519. Ill., index. California State Printing Office, Sacramento, 1914. For sale by State Mining Bureau, Ferry building, San Francisco. Price, $2.

This is an important book to those who are interested in one of the greatest industries in the state of California. The folio of maps that accompanies the report was published a month earlier than the book. It was reviewed editorially in the *Press* of March 27, 1915.

Given ample authority to ascertain and present facts of the business as well as the technical side of the oil deposits, and qualified by ample experience, the authors have presented a new idea in publications of this character. Of the newer points, first come extensive graphic diagrams of well-production records, classified by oilfields. These are intended to shed empirical light, as it were, on the important question of how much oil can reasonably be expected to be won from various areas. Since this problem is governed by the influence of a number of complex factors, such as water-encroachment, value of product, production costs, etc., data thereon are welcome. The discussions accompanying the diagrams are inconclusive as to what might safely be gathered from the evidence given. Data on the personal factors in the oil-production, refining, and marketing business in California are intelligently discussed. There is also given the results of some experimental work lately done to determine the evaporation losses in oil-containers; it clearly shows that there is good scope for further research work of similar character.

The treatment of the subject as a publication on a basic industry is excellent. It is known that to cover adequately any single branch would require a volume; judicious selection of subjects as well as material was therefore necessary. Refining of oils, concerning which few are intimately conversant, is passed. The uses and applications of crude oil and gas in commerce, of greatest importance on the Pacific coast, are treated at fair length. The geology of the main producing oilfields is covered by presenting the generalized results, by competent authority, of the more extended geological investigations in recent years, while that of prospective fields is covered efficiently mainly by the original work of the assistant author. On the side of oil-production, the branch that has suffered most from the lack of proper technical guidance, excellent data are given in a rational way on both well-drilling and pumping-costs; the application and cost of the various forms of power, steam, gas, electricity, to these steps in production are described adequately. The cost of pipe-line carriage of oil, as given, directs attention to the profits made in this line of the industry, where concerned with such production and long-lived fields as obtain in California. The menace of water-flooding of the oil measures in many of the fields is forcefully discussed. The self-interest of operators has not been strong enough in this late period of low-priced oil to fight water-encroachment effectively; with poorly constructed state statutes, and with no arm to lean upon from the Federal side, it is most opportune for the State Mining Bureau to stand out strongly for measures designed to arrest further damage from this ever-pressing evil.

The discussion on the price of oil, the goblin that forever casts shadows (whether good or evil) across the slumbers of the oil-producer, seems to lead to but one conclusion, apparently somewhat reluctantly expressed. In effect, it is, that unless some restriction is placed (by statute?) on indiscriminate drilling, at least during periods of flush production, there is not much chance for the price to rise to a level commensurate with the risk, or even to a level high enough to cover cost of production to the average producer. This condition applies with special force to the present situation in California where the large sellers, few in number, and equipped with millions of capital, are in command with larger production of much newly proved acreage of great potential yield, and as yet but slightly drilled.

The book treats of important and interesting phases of the industry, the facts concerning which are not always available to the public. Interspersed with the statements of facts are opinions bluntly and pointedly expressed, which add to the interest of the reader. It might be said that the financial end has not been as fully described as it could have been, particularly the dividends. The folio accompanying the book presents both geologic and field maps brought up to September 1914. The maps are comprehensive, on a good working scale, and are excellently done. The appearance of the publication at this period, when there is considerable legislation pending, both Federal and State, that may affect not only the character of the future development of the oilfields, but the policy of handling the lands, is both timely and important; this aside from its evident value to those concerned with producing and handling the product.—J. H. G. W.

MINING DECISIONS

MINERS' LIENS IN COLORADO—EFFECT OF LEASE

Persons working a mine in Colorado under an assignee of a lessee were not entitled to a lien for their services merely because the lease contained an option to purchase, as the lien law does not apply to an owner who leases insofar as employees of the lessee are concerned. No notice of non-responsibility of the owner is required to protect his property against liens for work done under authority of such a lease.

Grimm *v.* Yates (Colorado), 145 Pacific, 696. December 7, 1914.

MINERS' LIENS—ARIZONA LAW CONSTRUED

Paragraph 3654 of the Arizona Civil Code of 1913, giving laborers on mining claims a lien for labor by virtue of a contract between them and the owner or his agent, trustee, receiver, contractor, or purchaser under option contract, cannot apply to an owner giving an option contract to sell prior to the enactment of this provision, for otherwise the provision would be both retro-active and an impairment of the obligation of a contract in violation of the Constitution.

Foltz *v.* Noon (Arizona), 146 Pacific, 510. February 20, 1915.

UNDERLYING MINERALS—SEVERANCE OF TITLE

The possession of the owner of the surface of land is not adverse to the title of the owner of the coal and minerals beneath the surface; on the contrary, it seems that such surface possession inures to the benefit of the owner of the underground minerals. A conveyance of the underlying coal with the privilege of its removal from under the land of the grantor effects a severance of the right to the surface from the right to the underlying coal, and makes them distinct corporeal hereditaments. The owner of the minerals does not lose his right by any length of non-usage. He must be dismissed to lose his right, and there can be no disseizin (an unlawful dispossession) by an act which does not actually take the minerals out of his possession.

Shrewsbury *v.* Pocahontas Coal & Coke Co. (West Virginia), 219 Federal, 142. November 5, 1914.

COMPANY REPORTS

AMERICAN TELEPHONE AND TELEGRAPH COMPANY

Telephones are used for rapid communication with mining districts, and are used about mines, therefore an abstract of the 1914 report of this great Company is not out of place in a mining journal. It is best shown in tabulated form:

	1914.	1913.
Stations	8,648,993	8,133,017
Length of wire, miles	17,475,594	16,111,011
Underground conduits, value	$194,200,000	$181,500,000
Daily average connections	27,848,000	27,237,000
Plant additions	$ 50,045,300	$ 54,871,856
Gross revenue	225,952,123	215,572,822
Net revenue	59,247,279	58,689,523
Interest	18,940,641	16,652,624
Dividends paid	30,304,186	30,301,705
Depreciation	41,496,240	37,739,991
Employees' benefit fund	8,889,750	8,919,335

NORTH STAR MINES COMPANY

This is the company operating at Grass Valley, California. The report covers the year 1914. The story of this famous enterprise appeared in our issue of October 10, 1914.

Development work in the North Star mine consisted, chiefly, in the extension of drifts and rises on or connected with the 3000 and 3400-ft. west levels, and in sinking the main shaft from 5850 to 6361 ft., and cutting stations at 5600, 6000, and 6300 ft. Work in the upper levels resulted in the discovery of some good ore on and above the 3400-ft. level, warranting the expectation of a considerable tonnage in this part of the mine, not previously counted on. The shaft disclosed, for the most part, a good-sized but barren vein. It is hoped that the levels now started at 5600, 6000, and 6300-ft. will reveal the downward extension of the profitable orebodies found on the 5000 and 5300-ft. levels. The total development amounted to 2053 ft., including shaft-sinking, 511 ft., driving, 954 ft., and rising 588 ft. In cutting the stations, a total of 5183 tons of waste rock, equivalent to about 57,000 cu. ft. of material, was removed and hoisted to the surface. Owing to the nature of the exploration work, a comparatively small amount of development ore was produced during the year, the total being 2117 tons, as compared with 6420 tons in 1913. The additional tonnage developed or indicated on and above the 3400-ft. level will offset to a large extent the tonnage mined during the year.

The output was derived chiefly from stopes above the 3400, 4000, and 4400-ft. levels, and was obtained from 113,502 tons of rock mined and delivered to the mills, of which a total of 6252 tons was sorted out as waste, leaving 107,250 tons of ore crushed, with an average yield of $10.40 per ton. The average cost was $4.92 per ton for operating, and 51c. for development, making a total of $5.43 per ton crushed, $5.14 per ton mined, and leaving a realized profit of $4.97 per ton crushed.

During the year the gross production of the North Star mine was $1,115,587, obtained at a cost for current operation of $527,875. Outlays during the year on account of property purchase and improvement amounted to $12,681, leaving a balance of $520,568. Interest and dividends on invested funds amounted to $39,547, increasing the total net earnings for the year, before deduction of allowance for depreciation, and apart from the result of operations at the Champion mines, to the sum of $560,115. Dividends amounting to $450,000, 10% on the capital stock, were paid during the year.

Development work was actively continued throughout the year on both the Champion and Merrifield veins to the extent of 4047 ft. of drifts and rises, with the further development and promise, principally on the Champion vein, of a considerable tonnage of fair ore. The workings are spread out over a wide area, and it is difficult at present to operate the property to the best advantage. The results obtained during the latter half of the year, however, seem to give promise for the future, and it has therefore been decided, with a view to the more economical opening and working of the mines, to enlarge and extend the Providence shaft, situated some distance south of the Champion shaft, through which work is at present being conducted. The Champion mine produced 15,050 tons of ore averaging $6.684 per ton, totaling $301,103. Expenses amounted to $282,733, or $6.276 per ton, leaving a profit of $18,370. Improvements and purchase of property reduced the surplus to $2433.

At the end of 1913 the company's balance sheet showed a credit of $915,480, and at the end of 1914, $1,019,083. The latter consisted of cash, $319,033; investments, $586,430; bills receivable, $73,000; and supplies, $40,620.

IRON SILVER MINING COMPANY

This company operates at Leadville, Colorado, in charge of George O. Argall. His report for the year ended December 31, 1914, contains the following information:

Development in the Moyer, Tucson, and Blind Tom mines totaled 4914 ft. The main shaft of the first named was retimbered from No. 2 level to the surface, and the old boiler-plant was re-erected in another locality. These alterations resulted from settling of abandoned stopes. The east ore-shoot continued to yield most of the Moyer output, but it is now nearly worked-out. It has been possible also to sell low-grade mixed sulphide ore, and so maintain the yield. Development is being continued, and the area around both shafts to be prospected to the middle of the blue limestone formation. The area below this is receiving systematic geologic study, but diamond-drilling does not offer encouragement. The future of the mine is uncertain. In the Tucson, development was slightly greater than in 1913, covering a wide area, which outlined the main zone of mineralization. All of the known carbonate orebodies were extracted, and prospecting did not reveal others in the oxidized area of the mine. One hundred feet below No. 4. level an important zinc-lead sulphide mass was found. On No. 8 level, 399 tons of silicious silver-bearing ore, with a net value of $66.10 per ton, was mined. This occurs in thin seams and incrustations lining small cavities surrounded by dense quartzite, resulting in small production and high cost.

The output of the property was as follows:

Class of ore.	Moyer, tons.	Tucson, tons.	Blind Tom, tons.	Lessees, tons.
Zinc-lead sulphide	6,781	12,416	...	3,684
Low-grade zinc-lead sulphide	7,134	.....	...	.....
Lead sulphide	9,658	.....	...	422
Iron sulphide	61	209	...	766
Lead carbonate	17	558	...	2,992
Zinc sulphide	....	312	...	281
Silicious sulphide	....	399	...	.....
Copper sulphide	....	38	...	.....
Iron oxide	....	.....	317	437
Zinc carbonate	....	.....	78	5,930
Total	23,651	13,932	395	14,512

Metals contained in these varied ores amounted to 923 oz. gold, 328,027 oz. silver, 10,608,734 lb. lead, 17,396,362 lb. zinc, 12,751 lb. copper, and 5,247,433 lb. iron.

Revenue from sales of ore, royalties, and miscellaneous totaled $421,661. The profit was $174,629, of which $100,000 was paid in dividends. The surplus on December 31, 1913, was $353,539, and at the end of 1914, $428,168.

New Machines and Devices

Information based on letters and catalogues from manufacturers, and staff observations.

Conveying, Elevating, Screening, and Mechanical Power Transmitting Machinery at the Exposition

On account of its position in the Pacific Coast machinery trade, and also by reason of the active work done by its president, Constant Meese, for the Exposition, it was but fitting that the Meese & Gottfried Co. should exert itself to make a noteworthy exhibit in the Palace of Machinery.

Surrounding the exhibit space, 63 ft. 6 in. by 89 ft., is a counter about 36 in. high and 26 in. wide, the top of which is covered with over 200 ft. of plate-glass, under which is placed about 100 photographic enlargements of some important machinery installations made by this firm. The massive rail is of a simple yet beautiful design. The entrances are of black marble mosaic, inlaid with the firm's initials in three-foot Old English letters of deep yellow brass. Within the space, arranged on pedestals of uniform design, are all the standard items which comprise the firm's line of machinery, both manufactured and agency goods, altogether about 100 different units. Here are shown all the various types of shaft bearings, hangers, friction-clutches, collars, couplings, sprockets, friction-drives, gears, and other apparatus.

Material-handling elevators and conveyors are shown in many different designs, such as: overlapping and spaced bucket-elevators, non-spill bucket-elevators, barrel-elevators, slat-conveyors, apron-conveyors, pan-conveyors, scraper-conveyors, and belt-conveyors. One of the last named, 24 in. wide, runs across the entire exhibit. Above it, working both ways, is a large automatic belt-tripper for discharging the load and distributing it evenly along both sides into bins below. This conveyor is driven by means of a motor connected by a Link-Belt silent chain-drive direct to one shaft of a Reeves variable-speed transmission. This latter device enables a variety of speeds to be imparted to the conveyor through the other shaft. Another interesting exhibit is the Link-Belt silent chain-drive set, comprising a nest of silent chains operating at high speeds. Also a slotted viewing-disc, which, by the periodicity relation between chain pitch, speeds and apertures in the opaque disc, allows of a study of the tooth action, and apparently slow meshing and unmeshing of chain and gear teeth, which are actually traveling at a speed of about 1800 linear feet per minute.

Still another attraction is a large M. & G. steel-rim pulley, 108-in. diameter by 24-in. face. The caps of both bearings are removed to show the revolving oil-rings, and though this pulley is revolving at a considerable speed, there is, as far as the observer can detect, nothing to make it go.

Other exhibits of special interest to rock and gravel producers are a large revolving screen 48 in. diameter by 18 ft. length; an installation of conical screens showing arrangement of bearings, drives, chutes, sand-settling apparatus, etc.; rock-bin gates; automatic or reciprocating feeders, and other machines.

Some of the firm's agency goods deserve more than passing notice. One is a Gilbert wood pulley in process of construction. An American all-steel pulley, 24 by 72 in., is shown; also Cumberland ground-steel shafting, from $\frac{1}{2}$ to 6 in. American pioneer pressed-steel hangers and other shapes are shown.

Meese & Gottfried's manufacturing plant and main offices are in San Francisco. It also maintains branch houses with resident engineers at Los Angeles, Seattle, Portland, and Vancouver, British Columbia.

Commercial Paragraphs

The Hecla Mining Co., Idaho, has purchased a 5 by 6-ft. adjustable quick-discharge tube-mill of CHALMERS & WILLIAMS manufacture.

The first of the 10-ft. mills for the Anaconda company was shipped from the HARDINGE CONICAL MILL CO.'S Pittsburgh works two weeks ago.

The TERRY STEAM TURBINE CO. announces that the United States court at Boston, on March 13, sustained the validity of patent No. 741,385, owned by the company.

A 30-page booklet, containing 46 pertinent paragraphs dealing with its telescopes and accessories, has been published by the BUFF & BUFF MANUFACTURING CO., of Jamaica Plains, Boston, Massachusetts.

The Denver office of the SULLIVAN MACHINERY CO. announces that after May 1 it will be at 837 Equitable building, and that it will continue to carry the same stock as heretofore. George W. Blackington is manager.

In *Bulletin* No. 34-M, the CHICAGO PNEUMATIC TOOL CO. describes its class 'O' 'Chicago pneumatic' steam and power-driven compressors. Details are given on frame, bearings, cylinders, valves, regulator and unloading mechanism, and indicator cards from full load to the fourth step in operation.

The LUNKENHEIMER COMPANY, Departmento de Exportacion, Nueva York, E. U. A. Catalogo ilustrado y lista de precios en Español. Ese catalogo comprendiendo valvulas de bronce y de fierro, silbatos, llaves, manometros, inyectores, lubricadores, bombas de aceite, copas para aceite y grasas, y multos otros cosas. El compañía Lunkenheimer han sido estableciendo por muchos anos en ese pais y otros y el catalogo contiene mucho de interes para todos ingenieros y mecanicos que quieren informes sobre mercancias de ese clase.

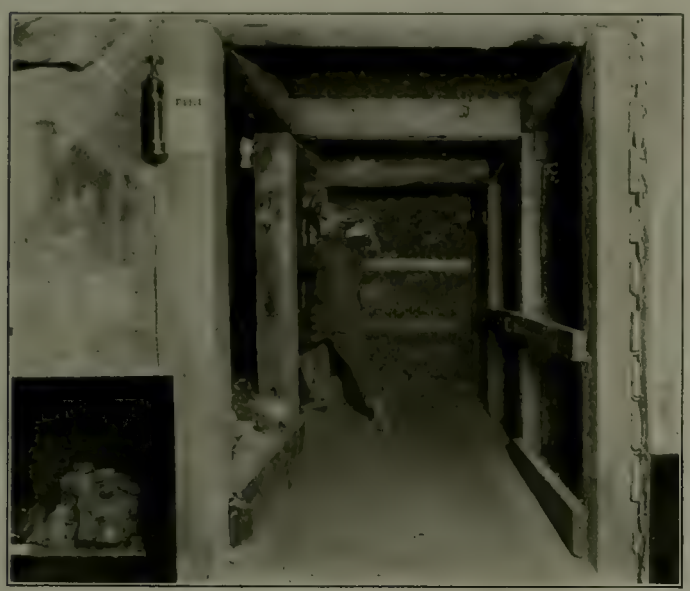
The DEISTER CONCENTRATOR CO., of Fort Wayne, Indiana, recently placed on trial one of its No. 3 tables in the Colburn-Ajax mill, Cripple Creek, and after a short time received an order for seven more slime-tables; and further, four more slime and one sand-table. The Company has just issued a catalogue covering the latest improved No. 3 slimer, which it claims does good work on feeds of 80-mesh and finer; the No. 3 double-deck slimer; the No. 5 Deister ore concentrator for fine and coarse sand feeds; the No. 5 double-deck ore-concentrator for fine and coarse sand feeds; and No. 4 ore-concentrator for fine and coarse sand feeds. Seven pages, with a plate, are devoted to a description of the driving-mechanism used on all Deister reciprocating-tables. The Overstrom single and double-deck tables are discussed, with parts. Also the Deister ore-concentrator multiple-deck slimer, for very fine slime and overflows. An extra list is given of incorporating improved parts, many of which are interchangeable in the older type machines

Thirty additional pages have been published since the above was written. These are to be inserted in the catalogue. Machines discussed are the latest improved No. 3 double-deck slime table, the double-deck No. 5 ore concentrator, and the single and double-deck Overstrom tables. During January a No. 3 Deister machine was installed in the Colburn-Ajax mill, Victor, Colorado. Further orders for the same plant consisted of seven slime tables, and four slime and one sand table respectively.

Mining and Scientific Press

Edited by T. A. RICKARD

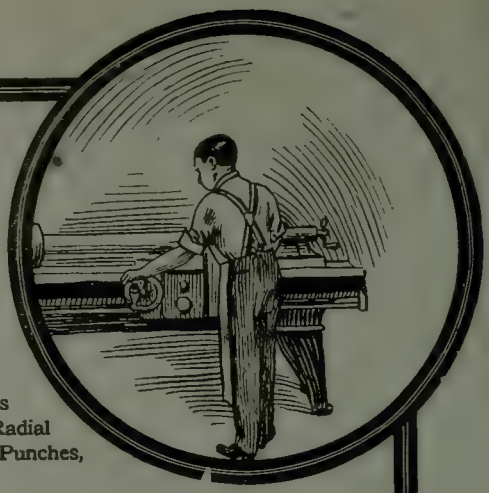
Volume 110 SAN FRANCISCO, MAY 1, 1915 Number 18



Yes; it does look like the real thing. It is part of the model mine at the Panama-Pacific Exposition.

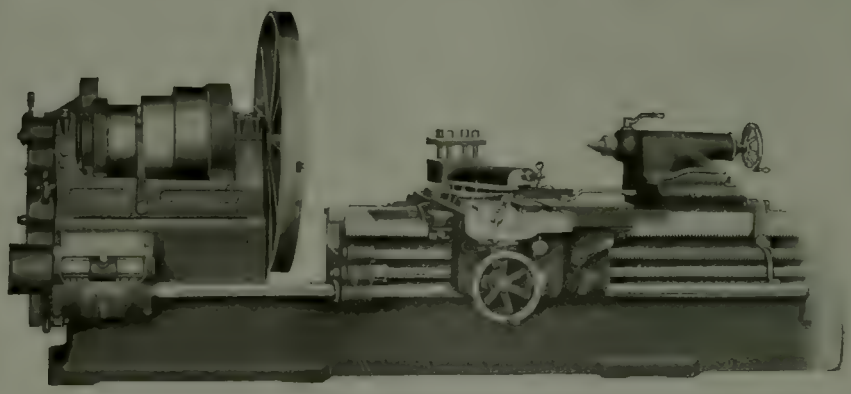
In the model foreman's office you find the PRESS, of course. A description of The Mine appears in this issue.

Machine Tools



WE CARRY ONLY THE BEST
LINES of REAL MACHINE TOOLS

Our Denver Stock includes various sizes and styles of Lathes, Planers, Shapers, Millers, Drill Presses, Radial Drills, Grinders, Bolt Machines, Pipe Machines, Punches, Shears, Power Hammers, Etc.



Every tool in stock is designed to meet the requirements of some particular line of work. For instance, the lathe shown is designed for a universal lathe of large range, to be used in repair and jobbing shops. In other words, for just such work as YOU have for repairing MINE AND MILL MACHINERY

Send for
Our Special Catalogue
"MACHINE TOOLS" No. 30

Special Tools for Special Purposes

We will gladly furnish prices, special literature, etc., for your estimates

NOTES 673

THE ZINC MARKET 674
Existing conditions are abnormal and therefore an unsafe guide to future development.

OILS AND FLOTATION 675
Oils are substances of great complexity; their use in flotation is an inviting field for research.

THE PLACE FOR ORE 676
Indications as to likely places to search for ore are invaluable guides to the prospector and miner; instances are given.

DISCUSSION

DEMOCRACY AT LAKE SUPERIOR.
By P. B. McDonald 677
An engineer of experience in the Lake Superior region is inclined to agree that the region is less democratic than others in the United States.

THE MECHANICAL WORK OF CRUSHING.
By Algernon Del Mar 677
A contribution to the discussion of Rittinger's law initiated by H. C. Kenney.

WAYS THAT ARE DARK.
By Alfred H. Hale 678
A suggestion as to the material used in salting samples, and further instances of the practice.

ARTICLES

CONSTRUCTION OF UNDERCURRENTS.
By C. S. Haley 679
These devices, so efficient in saving fine gold in hydraulic operations, are easily made. Detailed instructions for the construction of various types are given.

THE FLOTATION OF COPPER ORES.
By An Occasional Contributor 680
Inorganic oils give better results with copper ores; organic oils are more effective with lead and zinc ores. The applicability of various oils to copper ores is discussed, and the methods to be applied in practice are reviewed.

MINERAL INDUSTRIES OF BRAZIL 682
Diamonds and semi-precious stones are the chief mineral products. Some iron ore is smelted, 200,000 tons per year of manganese ore is exported. There is only one small coal mine; the copper industry is at a standstill.

THE MOUNT ELLIOTT MINE, CLONCURRY, QUEENSLAND.
By W. H. Corbould 682
The district is 200 miles long and 40 miles wide, with several scattered mines, of which the Mount Elliott is the most important. This has produced 45,000,000 lb. copper, 36,000 oz. gold, and 28,000 oz. silver. Working costs are given.

KNOWLEDGE AND RESEARCH. Page.
By R. W. Raymond 683
The difference between knowledge and research is the difference between the expert who knows what has been done and the discoverer who has a vision of what may be accomplished. Research must be based on knowledge, otherwise the fancied pioneer may find himself digging in ground exhausted and abandoned by others. And to make his work really useful the discoverer must also describe and define his achievement, otherwise his labor is in vain.

THE MINE—AN EDUCATIONAL EXHIBIT.
By The Editor 686
At the suggestion of the Bureau of Mines and with the co-operation of various mining companies and machinery manufacturers, a realistic exhibit of mining conditions has been made beneath the floor of the Palace of Mining and Metallurgy. The editor records his impressions.

AIR-BLASTS 690
Deep mining in the Lake Superior copper region is complicated by the rock pressure, which leads to crushing of the ground and collapse of the excavations, producing air-blasts of dangerous violence. The means taken to prevent their occurrence are described.

THE KENNEDY DAM.
By John S. Eastwood 691
The feasibility of mining operations, in some regions, hinges on the cost of storage of the tailing produced. Multiple-arch concrete dams are quickly and cheaply built. Full details as to such a dam recently constructed by the Kennedy Mining & Milling Co. are given.

AUSTRALIAN ORES AND METALS AT THE EXPOSITION 694
Australian mineral products are not displayed in the Palace of Mining and Metallurgy, but are housed in the Australian building. Gold, silver, lead and zinc, copper, tin, coal, and gem mining is well portrayed.

"Ingersoll-Rogler" Class "PRE" installed by Maryland Steel Company, Sparrows Point, Md.

"Ingersoll-Rogler" Air Compressors

CLASS "PRE"

The mine or industrial plant contemplating the installation of an air compressor will do well to investigate the direct connected, electrically driven, "Ingersoll-Rogler" Class "PRE".

This type represents the maximum value—not only in initial investment, but also in operating efficiency, low maintenance cost and absence of shutdowns for repairs. It is a compact unit, automatic in operation and requires a minimum of attendance. A few of the features which have earned for the "Ingersoll-Rogler" Class "PRE" an enviable reputation are:

- Ingersoll-Rogler Inlet and Discharge Valves.
- Automatic Splash Lubrication.
- Automatic Clearance Controller.
- Simple in construction, durable and noiseless in operation.
- Highly Efficient Cooling System.
- Cleanly, economical and proportioned to speed.
- Giving close regulation through five stages.
- Complete cylinder jacketing improved intercooler.

Bulletins 3008 and 3034, which fully describe these machines, will be sent upon request.

EDITORIAL

T. A. RICKARD - - - - Editor THOMAS T. READ - Associate Editor

WE are glad to state that our correspondent in Mexico, Mr. Leonard Worcester, arrested at Chihuahua on February 13, on orders from Francisco Villa, has been released, and is now out on bail. Thanks are due to the Secretary of State, Mr. Bryan, whose department made every effort to correct a grave injustice.

IN this issue we publish a description of the mine at the Exposition. For the excellence of this exhibit the credit belongs to a committee consisting of Messrs. H. M. Wilson, of the Bureau of Mines, Charles E. Van Barneveld, chief of the Department of Mines and Metallurgy, W. C. Coffin, Frank Harrison, and H. M. Wolflin.

PROHIBITION is invading every corner of the community. Among other manifestations of the effort to promote abstinence, we may mention that a general meeting of the Mining & Metallurgical Club of London was called recently by its president, Mr. Edgar Rickard, with a view to taking a vote on the proposal to discontinue "the sale or consumption of wines, spirits, beers, or other alcoholic beverages in the Club premises during the continuance of the War." We learn that a lively debate ensued, that many amendments were proposed, and that, in default of the possibility of carrying any resolution unanimously, the project had to be abandoned.

FREDERICK W. SEWARD, who died on April 25, was Assistant Secretary of State in the cabinet of Abraham Lincoln. He was the son of William H. Seward, who, when Secretary of State, in 1867, arranged the purchase of Alaska from Russia for the sum of $7,200,000, of which $200,000 was paid for the property of the Russian company at Sitka. To Seward also the new territory owes its name. At the time of the purchase he was severely criticized, but he had been in the North and knew what he was doing. "What, Mr. Seward," asked a friend, "do you consider the most important measure of your political career?" "The purchase of Alaska," he replied, "but it will take the people a generation to find it out." He was justified long before another generation had come and gone. It was an act of far-seeing statesmanship.

FLOTATION just now is a litigious subject, but the article we publish on another page does not trespass on the respect due to the courts of law. Our 'Occasional Correspondent', who is peculiarly fitted to write on this highly technical subject, describes the various kinds of oil employed. The use of the word 'acid' in connection with oily liquids has puzzled the judiciary of more than one continent. To the average man, 'oil' and 'acid' sound antithetic, the one being synonymous with smoothness and the other with acerbity. In this branch of ore-dressing, however, it is the physical rather than the chemical characteristic that counts. Some of the organic acids—such as crude carbolic acid—have oily properties that render them particularly suitable for the treatment of some ores. No one oil can be used effectively on all ores; indeed, this process illustrates one of the kindergarten principles of metallurgy, namely, the adaptation of the process to the ore. As regards flotation, the ordinary chemical analysis of an ore does not suffice to indicate whether it is amenable; physical conditions, of a character not yet satisfactorily defined, are decisive. Referring to treatment of copper ores enriched by chalcocite, our correspondent expresses confidence that flotation is practicable, as against a statement made by the author of the only textbook on the subject. We are glad to lay emphasis on the fact that this difference of opinion now has only an academic interest, because large tonnages of chalcocite ores are being treated successfully, notably at the Inspiration, Chino, Utah Copper, and Nevada Consolidated mines. On this and other points we invite contributory comment.

HABITUAL inaccuracy of statement is so confirmed a characteristic of the daily press, especially in technical matters, that criticism of them is hardly worth while. However, in a recent issue of an evening paper in this city there appeared a big-type heavily-leaded editorial the text of which was marked by an ignorance

not to be surpassed even by the worst forms of gutter journalism. Under the satirical title 'Generosity of a Copper Company', an attack was made on the Calumet & Hecla Mining Company. An attempt was made to show that this particular company was posing as a benefactor to its employees while in truth it was cynically mean to them. It was stated that the company has 12,000 employees, receiving $600,000 per month, or $50 per man; that the wages had been increased recently 10%, that is, to $55 per month; that this was "no raise at all" but a restoration of wages "to the scale paid before the strike of 1913"; that the company had "taken $14,000,000 from its men's wages during the past two years." This is a tissue of errors. The company normally has 10,000 men on its payroll; the average wage is nearer $100 than $50, miners receiving from $3.10 to $3.50 per shift; in May 1912 wages were increased 10%; the strike of 1913-1914 affected hours of labor, not wages; on September 1, 1914, a 10% decrease in the men's wages was made in consequence of the collapse of the metal market; the salaries of the staff were decreased concurrently 15%; at that time the price of copper was 12 cents per pound, as against a price of 14c. during the first half of 1914. Obviously the $50 per month and the $14,000,000 robbery are fictitious. The whole tone of the comment is grossly misleading and unfair.

The Zinc Market

The arrival of 6000 tons of zinc concentrate by the steamship *Sydic* at Galveston, from Australia, is a significant event. We understand that 85,000 tons of similar material has been consigned to this country from Broken Hill, New South Wales. What does it portend?

The three facts dominating the price of zinc at this time are the curtailment of European and Australian production, the innocuous desuetude of the cartel in Europe, and the demand for zinc in the making of brass to be used in the manufacture of munitions. All three are consequences of the War. The zinc from Broken Hill is exported as a 46% concentrate, most of which, before the War, was treated in Belgium and Germany, only a minor part of the output going to the Seaton Carew smelter, of the Sulphide Corporation, in England. The cartel is a syndicate of metal-merchants organized to control the market for zinc. In this syndicate were Aron Hirsch & Sohn, Beer, Sondheimer & Co., the Metallurgische Gesellschaft of Frankfurt, and the Vieille Montagne. Thus constituted the cartel exercised an unhealthy dominance, of which we may have more to say at another time. Just now its activities are extinguished. Control has passed, for the moment, to this side of the Atlantic. At the present time the production of zinc in the United States is at the rate of 600,000 tons per annum, while the smelter capacity is only 450,000 tons. If the Australian supply is to be diverted hither, it is obvious that the erection of further plant is imperative. But is this diversion temporary or permanent? That doubt has paralyzed many schemes on both sides of the Atlantic. Soon after hostilities began in Europe, an effort was made by the Hoover brothers, Mr. F. A. Govett, and others associated with the Zinc Corporation, to raise funds for the erection of a large up-to-date zinc-smelting plant in England. A representative of the Guggenheims also visited London last November with a view either to joining this enterprise or of erecting a separate zinc smelter in Europe: in Wales or Spain. Money and talent were available, but several obstacles were uncovered. Labor conditions in England are not favorable to smelting enterprise; nor is the fume nuisance a negligible point; but the decisive factor is the existence of contracts between the Broken Hill companies and the smelters in Germany and Belgium. These contracts are suspended, not abrogated, by the War. That is the view taken by the English courts. Wise men do not buy into litigation. There has been talk that the Federal Government of Australia might declare these contracts with enemy-aliens to be contrary to national interest, and outlaw them, leaving the question of compensation for final settlement between Great Britain and Germany when terms of peace are arranged. But nothing of the sort has been done. Obviously it is inadvisable to tamper with international law, which, in this case, is clearly against a hasty denouncement of the contracts rendered inoperative by the incidence of war. Of course, not all of these contracts are for long terms; some of them must expire shortly. But that is not the only trouble, at least as regards the American market. Should the zinc concentrate be shipped to the United States, there is a chance of an embargo being levied, like the export duty that killed the shipment of tin concentrate from the Malay States just as the tin smelter at Bayonne, New Jersey, was finished in 1903. That lifts a warning finger to those thinking of erecting smelters to treat Australian concentrate. The Australian Government might be influenced or coerced by labor leaders raising the cry for the smelting of Australian ore in Australia, which, after all, is the economic ideal, if only the cost and amenability of labor had not rendered it impracticable in the past. Furthermore, there is the duty on imports of zinc ore into the United States. Now the duty is small, it is only 10% on the gross value of the zinc in the ore, but should the market for the domestic output suffer unduly from foreign imports it is more than likely that a prohibitive tariff would be demanded, successfully. Those controlling the bigger mines in Australia might join with the larger producers in the United States with a view to regulating the market; this can be done, for the joint output represents fully 52% of the world's entire production; but the many owners of small mines in Missouri, Wisconsin, and Oklahoma might resent the importation of Australian concentrate and make an unpleasant noise at Washington. In 1914 the United States produced 364,000 tons of zinc and consumed 314,000 tons. Now the production is 600,000 tons, all of which is being consumed, for the output is sold up to September at 9½ cents per pound, as against a price of 4.8 cents in July last. The average cost, including interest on capital expenditure, is estimated at 5.4 cents

per pound. In short, existing conditions, owing to the War, are abnormal, and therefore afford no safe guide for estimating business in the near future. On the whole, the best solution of the question how to dispose of the Australian production is the restoration of the Belgian smelting industry, on the conclusion of peace, by aid of British capital. Meanwhile American mines can produce all the zinc that is required either for peaceful or warlike purposes, for the increase during the past year is more than equal to the whole Australian output.

Oils and Flotation

Oils have been used for centuries for a variety of purposes. The development of flotation as a metallurgical process has led to the study of these interesting substances from a new viewpoint, as their application to this process hinges on properties not previously utilized. Flotation, though complex in its application, is in principle a simple process. It depends chiefly on the fortunate fact that metals and their compounds in their natural state are less easily wetted by water than compounds of the other elements. This is equivalent to saying that the minerals of economic value are less easily wetted than valueless gangue-minerals, whence the process derives its usefulness in metallurgy. Minerals are heavier than water, but particles of them will float on a water surface because of the fact that each one has adhering to its surface a film of air. Similarly, a mineral particle wetted and submerged has a film of water adhering to its surface that bears to it a different relation from the remainder of the liquid, the molecules of water adherent to the surface being in a state of strain, which causes the development of molecular forces of surprising magnitude. The wetting of a dry particle of ore involves the displacing of an adhering film of air by a film of water, and, as we have already remarked, this does not easily take place with certain particles of minerals, to which the air clings with great tenacity. It is probable that such mineral particles, when submerged in water, are not actually in contact with the water but are covered with a film of air, like a diver in his water-proof dress. As the air is much lighter than the water, such a mineral particle has a much less specific gravity than it otherwise would. Presumably the thickness of the film of air is independent of the mass of the particle, hence the smaller the particle the less its actual specific gravity. We are not aware that research has demonstrated this to be a fact, but, if true, it would go far toward explaining the difficulty experienced in ore-dressing in separating minerals of differing specific gravity when the particles are very small.

In common parlance, oil and water will not mix; in other words, a water surface adheres not at all to an oil surface. But oils do adhere to mineral surfaces with considerable tenacity, showing the same preference as air for the economic minerals. Most oils are also much lighter than water, and these two properties have been utilized in flotation in two quite different ways: If crushed ore is mixed with a considerable quantity of oil it adheres to the valuable mineral particles in considerable amount, forming an oil-mineral agglomerate that is lighter than water, and consequently floats, the oil buoying the heavy mineral just as a life-preserver buoys a swimmer. For various practical reasons this property is not of much use in ore-dressing in its simplest form; but if a small quantity of oil is brought into contact with the mineral, it seems to spread itself in an infinitesimally thin film over the mineral surface; at any rate, a minute quantity of oil will greatly increase the tendency of a large quantity of mineral not to be wetted by the water. Nearly everyone is familiar with the parlor trick in which the operator rubs his fingers on his hair and then draws a common sewing needle between his fingers in order to transfer a minute quantity of oil to its surface. The needle can then, by skilful handling, be floated on the surface of a glass of water, to the astonishment of the spectators. The forces involved in causing the water surface to support the needle, which has a specific gravity eight times that of water, are identical with those utilized in the flotation of ore. Agitation, with the resulting production of a froth, is employed because the amount of mineral that an air-water surface will support is comparatively small, while the aggregate surface of a collection of bubbles is great. Furthermore, the curved surfaces of bubbles seem more efficient than the normal flat surface of a liquid.

Oily substances are commonly classified into oils, fats, and waxes, roughly liquid, semi-solid, and solid substances. More exactly, oils are liquid, and fats are semi-liquid or solid glycerides, while waxes are combinations of fatty acids with monatomic alcohols. Waxes are usually solid, but the substance commonly known as sperm-oil is a liquid wax. Even this definition does not cover the case, for crude petroleum and the variety of substances that may be separated from it are not included. These are hydrocarbons belonging to the paraffin series, C_nH_{2n+2}; the olefin series, C_nH_{2n}; the acetylene series, C_nH_{2n-2}; the terpene series, C_nH_{2n-4}; the benzene series, C_nH_{2n-6}; and so on almost *ad infinitum*. Such hydrocarbons are known as the inorganic oils: the organic oils being divided into animal and vegetal oils, according to their origin. Animal oils are produced from the fatty substances found in the bodies of animals. These substances have no direct function in the animal metabolism, and it is generally believed that they represent a sort of savings bank of the excess of food eaten by the animal beyond its daily requirements, which is thus stored away as a safeguard against periods when food is scarce. But the oils formed in plants clearly have no such function, and it has not been explained satisfactorily why the plants produce them. The origin of inorganic oils is shrouded in mystery, the older theory being that they have been produced from the inorganic remains of fossils. The difficulty with this explanation is that inorganic oils are entirely different in chemical composition from organic oils, and the production of them from organic substances would

involve the action of reducing processes under conditions in which it would be more natural to expect oxidation. The advocates of the theory of inorganic origin have recently made a good deal of progress toward establishing their hypothesis.

It is thus seen that the general subject of oils is a decidedly complicated one. The flotation investigators have detected a new complication, since, as pointed out in the valuable article on flotation appearing on another page in this issue, oils of inorganic origin give better results on copper ores, while vegetal oils give the best recovery on zinc and lead ores. Furthermore, different samples of the same oil give widely differing results. This may possibly be due to the fact that all commercial oils are mixtures of several substances of diverse composition. It is not impossible that investigation may prove eventually that it is not the oil which does the work, but some other substance which is present in minute and varying amounts in the oil. On the other hand, there may be some substance present that interferes with good work. This is only one of the many problems connected with the practical application of flotation that are as yet imperfectly understood. The whole field invites research.

The Place for Ore

The miner's search for mineral riches is guided by many considerations, most of which he is rarely able to explain in so many words. Theories, of course, he has. But his best guide is an instinct developed by actual experience. One of them is the feeling that certain kinds of rock are favorable to the existence of the particular ore for which he is seeking. The Cornishman will tell you that 'killas', or clay-slate, near granite is 'kindly' to tin, while the prospector in Colorado when searching for silver-lead ore will look for limestone. As the old miner says: "The nature of the rock is congenial to the formation of mineral." And so it is, even if the man with the pick has to look to Harvard or Yale to tell him the true inwardness of the phenomenon. A sort of empirical geology was evolved long before scientific explanations had been established, if they can be said to be established even now, save in a general way. It has been ascertained that certain rocks are peculiarly associated with deposits of particular metals, for example, silver-lead with limestone, quicksilver with serpentine, copper with schist, gold with slate, and so forth. But the generalization is punctured by exceptions. We find that the favorable kind of rock is not enough; there must be structural conditions indicating a period when thermal solutions were able to circulate and precipitate in the specific locality. And of such structural conditions the contact with an eruptive seems to be decisive; also the presence of a specially permeable or soluble stratum, zone, or band, assisting and compelling the chemical reactions precedent to a concentration of ore.

Among the deposits illustrating these elementary considerations we may instance the flat orebodies in the quartzite at Redcliff, Colorado. These have been described and discussed at intervals for 30 years, from S. F. Emmons before the Colorado Scientific Society in 1886 to Mr. A. H. Means in an interesting article appearing in the latest issue of *Economic Geology*. Near Redcliff the Eagle river has cut a deep cañon, the cliff on the eastern side exposing a geologic section that includes Archean granite, Cambrian quartzite, and Carboniferous limestone, with a porphyry that is probably of Tertiary age. In the limestone are replacement deposits of zinc-blende, associated with pyrite, chalcopyrite, and galena. In the granite are fissures containing gold and silver, associated with pyrite, chalcopyrite, galena, and zinc-blende. We are chiefly concerned for the moment with the ore in the quartzite. This takes the form of flat masses or floors of sulphide ore, largely oxidized, connected with fault-fissures that are rich in the precious metals and extend into the basal granite. Leaving the more obscure features, we note that the rich ore, containing crystalline gold of great beauty, is found on the floor of cavernous spaces in the quartzite, notably where it has been traversed by the fissures that penetrate the rocks both above and below this particular geological horizon. Apparently the enriching mineral solutions, spurred into activity in the wake of the porphyry intrusion, ascended from the granite, forcing a devious passage through the overlying strata until they found conditions favorable to precipitation. The magmatic waters may have been compelled to deposit their metallic contents by reason of reactions with descending waters encountered at this horizon. Similar explanations apply to many districts; but what, it will be asked, was the factor that determined the localization of ore in the quartzite? Here Mr. Means offers fresh evidence It was the existence of a zone, 20 to 60 feet thick, of sericitic alteration, that is, the grains of quartz in the quartzite have been replaced marginally by sericite, a secondary variety of white mica, thus creating interstices filled with sericite, and fine pyrite also. This furnished a zone of relatively greater permeability and solubility. Likewise the overlying limestone, by its solubility, furnished another favorable zone, emphasized by an impervious cover of porphyry. Many analogous cases might be quoted. We shall refer to one, that of the rich blanket-orebodies of Newman hill, at Rico, also in Colorado. There the solutions rising along fault-fissures were brought to a stop by a stratum of shale, which broke the force of the fissuring by changing vertical faulting into lateral slipping. Under this relatively impervious shale there happened to lie a layer of gypsum, a mineral of easy solubility. That determined the place for ore. The flat bodies of sulphides, rich with native gold and argentite, have a strike that conforms to that of the veins, below them, whereby the ascending solutions were conducted to the gypsum. In the Black Hills of South Dakota a similar relation between 'verticals', as they are called, and 'contact' orebodies is observed. In the exploitation of them we obtain some of the most interesting illustrations of the application of geology to mining.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Democracy at Lake Superior

The Editor:

Sir—Rather startling, but perhaps true, is Mr. Read's suggestion in the *Press* of March 13 to the effect that life in the Lake Superior copper country is less democratic than in any district in the Western states. Most emphatically he is right when he says that the people of the district are not conscious of any lack of democracy. Indeed, so unconscious are the vigorous-minded people of the copper country of a lack of democracy, and so much good is mixed with the bad points of the system, that a not unpleasing semblance of democracy has long prevailed. It was only after fifty years of smooth going that serious labor trouble occurred. It is interesting to note that Mr. Read ascribes the peculiar social conditions existing in the copper country to the influence of early aristocrats (notably Alexander Agassiz) from that famous hot-bed of aristocracy situated on the bleak shore of Massachusetts bay. In this connection, many mining men have remarked at the complete change of social atmosphere experienced in going from the Michigan iron ranges, where a hematite-handed hospitality prevails, to the Keweenaw peninsula, a few miles to the north, where class lines tinge all intercourse, although usually not noticed in the light of other advantages which the attractive copper country offers. The influences, which early set the social standard on the Lake Superior iron ranges, I would call distinctly Cornish. There is one considerable district in the Michigan iron region where, up to a few years ago, one man was the dominant factor; and there never was a happier mining district anywhere, because this man was, and is, a democrat. What is more, he attracts the best miners in two states, and he does not do it by presenting them with libraries, hospitals, or visiting-nurses, or by giving prizes for flower-gardens. It is quite possible, as Mr. Read intimates, that all the paternalism and philanthropy which the copper-mining companies have lavished upon their employees, and of which they (the employers, not the employees) are so proud, has only served to emphasize the difference between master and man, and has aroused the envy of the workmen by giving them tangible proof of the large profits their labor has brought to (as they thought) idle men who seldom see the mines. I wonder is paternalism worth while—particularly in the mining business?

P. B. McDONALD.

Boston, April 2.

The Mechanical Work of Crushing

The Editor:

Sir—Summarizing the limited amount of discussion of the work done in crushing, we find that while the respective adherents of Rittinger and Kick indulge in mathematical athletics, there is a dearth of experimental proof.

Stadler says,* in reference to the statement that the work required to crush rock varies in proportion to the surface exposed: "This 'law' is a myth which has never been recognized by science and it is unfair to Rittinger's memory to connect his name with what is clearly nonsense." At McGill University it is stated that the final results of experiments were to disprove the laws of crushing enunciated by Rittinger and to prove Kick's law. So far is I know, these proofs have not been made public, nor the result of the investigation undertaken by the Mines Trial Committee in South Africa, although it has been hinted that the results favored the Rittinger theory; but one must remember that it would be rank heresy in South Africa to accept this theory. A. F. Taggart by mathematical reasoning proves Kick's law to be true within the elastic limit, and then assumes it to hold good for fracture.† A. O. Gates proves by actual experiments that Rittinger's theory is nearer the truth than Kick's law when the elastic limit has been passed. So the question naturally presents itself, why cannot this subject be decided by experiment, and not left to mathematical jugglery?

In a small way and by a limited number of experiments I have attempted a demonstration, the results of which are appended as well as a mathematical calculation showing how easy it is to prove both theories by mere figures.

I prepared a number of cement blocks of cubic form, with a single plane of weakness through the centre produced by imbedding a piece of tissue paper the size of one face of the cube, the paper being punctured with holes corresponding to half the area of one side of the cube. These were made in two sizes, with 2-in. and 1-in. edges. With a falling weight, to imitate a gravity stamp, I fractured 15 of these cubes and found approximately that a 3-lb. weight was required to drop 20 inches to fracture the 2-in. cubes and 5 inches to fracture the 1-in. cubes. A 3-lb. weight falling 20 inches produces 5 foot-pounds of work, while the same weight falling 5 inches

*Trans. I. M. & M., Vol. XX, p. 426 (1910-11).

†Trans. A. I. M. E., 1914.

produces 1¼ ft.-lb. The area of fracture or the surface exposed in crushing varied in the same proportion as the amount of work required to fracture the two different-size cubes, so that the work in crushing followed Rittinger's law, the formula being represented by the ratio of the original diameter D to the final diameter d, or D/d.

If n is the number of times a cube has been halved by fracture, then $\frac{1}{2}^n$ will represent the proportion of the original diameter, then $D/d = \frac{1}{\frac{1}{2^n}}$, therefore $\log D/d = n \log 2$. But $\log 2$ is a constant, therefore $k \log D/d = n$. But the work is proportional to n, therefore the work done in crushing is proportional to $\log D/d$. So here we have the work proportional to D/d and $\log D/d$, the former the Rittinger and the latter the formula derived from Kick's law. It is easy enough reasoning from first principles to prove that Kick's law applies to deformation within the elastic limit, but it is not necessary for our argument.

In your issue of April 10 is an able paper by Herman C. Kenney, who inclines to the belief that Kick's law applies to deformation without fracture until the elastic limit is passed, when the Rittinger law applies—in fact, that one law ends where the other starts. This he expresses by the equation:

Total work = work of compression + work of fracturing — work given back when the pressure is released. Gates‡ says: "At the so-called elastic limit the first break occurs some place within the body, releasing the energy locally absorbed at the point and allowing a further deformation without a proportionate amount of energy being absorbed. * * * And except as energy has been absorbed in making these breaks and any heating of the material has caused radiation losses, the individual crystals of the rock are allowed, upon release of the pressure, to return to their original form (in conformity with Kick's law, if I understand it aright), and in so returning to their original form they return the energy they contained."

If Kick's law is true to the elastic limit and Rittinger's law for fracture, we must then have some energy dissipated. This may be represented thus:

By Kick's law.		Rittinger law.		
Work done to elastic limit	−	Work of fracture	−	Work of radiated heat
Returned energy	=	Energy consumed in physical changes		

$$x = a + b + c + d$$

At the moment of fracture, heat is generated by friction of the sliding grains, together with the heat of compression, giving the total heat lost, convertible into foot-pounds of work. The pressure being released at the moment of fracture, work is done by the pieces returning to their original state of strain. By this line of reasoning we can show why Kick's law is far from true for fracturing, but to establish the Rittinger law we must show that b, c, and d bear fixed ratios to the size of the particles fractured.

The rise in temperature of any body due to compression or friction within itself is inversely proportional to the size of the particle, so that the smaller the particle the less work expended in compression; as this heat is a constant quantity for any substance, we may conclude that the loss of energy due to heat bears a fixed ratio to the size of the particle to be crushed. The returned energy will also bear a fixed relation because this depends upon the elasticity of the body, while the energy consumed within the body will likewise follow the same rule. I have, I believe, shown that while Kick's law is true to the elastic limit, beyond this Rittinger's law is approximately true for fracture, and the difference between the two amounts of work is made up of several factors that vary with the size of the particle to be crushed.

Ways That are Dark

The Editor:

Sir—In your issue of the 10th inst. you say, under the 'Waste of Experience,' that "the composition of the material used in salting suggests a question we should like to see answered by some of our readers."

One of the best 'salting' compounds for gold ore I know of is made, and has been used successfully, by fusing about 96% of gold and 4% of lead. As some mining engineers become suspicious when a gold ore does not show an appreciable amount of silver, 'expert metallurgists' add a few percentages of silver to the charge. The alloy is extremely friable, pulverizing about as easily as chalk. It has an advantage, not possessed by sylvanite, of being very heavy, and in wet ore is not readily washed away. Besides, the exact amount of gold added to the sample is easily determined, which is not the case where the telluride ores are used for salting, owing to the lack of uniformity in their composition. I am quite certain I could fill more than one issue of the *Press* with what I have learned in one way and another—mostly from experience—of the tricks that have been played in the ancient and honorable profession of mining. I have known of cases of the biter actually having a piece bitten out of him, figuratively speaking.

While I think what I have said about 'salting' may interest you, I believe you will agree with me that it would not be advisable to publish it?

Taking the inside out of a block of pay-ore is an old trick. The Telegraph mine in Bingham cañon, Utah, is an example. The mine—I have forgotten its name—that made Coolgardie, Western Australia, famous was secretly prospected by the owners by means of an independent shaft and a drift extending from it to beneath the ore in the rich pocket in which the actual working-shaft was sunk. The secret workings showed they were about to the bottom of the rich pocket. Then, like wise men, they sold out.

Denver, April 13. ALFRED H. HALE.

Construction of Undercurrents

By C. S. HALEY

The efficiency of the undercurrent in saving fine gold has been proved at many hydraulic mines. Some of the more common types of construction in use in different parts of the West, under varying conditions, may be of interest.

In the more remote portions of northern California, where almost everything but wire-nails has to be made on the ground, fir blocks about four inches thick and spaced about three-quarters to an inch apart, are used to make the riffles. The undercurrent-box itself, in a hydraulic mine of average size—say using a 20 to 36-in.

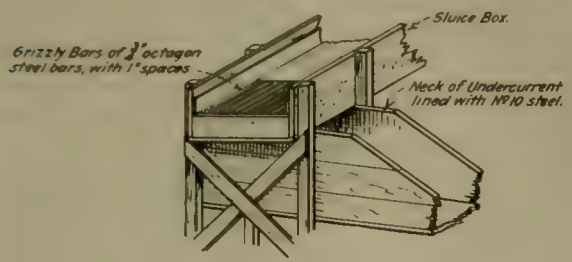

FIG. 1.

sluice—will be six to eight feet wide and from 12 to 24 ft. long. The sides will be of 10-in. boards, leaving a clearance of six inches above the blocks. The bottoms are usually of 16-in. stuff, 1¼ in. thick, and made of white fir or sugar pine. Such an undercurrent is shown in Fig. 1.

The inside of both bottom and sides is planed, and the joints made carefully, the sides being fitted and nailed before the box is put together. After this, soft wood is used for calking, and the cracks are carefully planed off. The blocks are usually cut in rectangles about twelve by six or eight inches, and spaced irregularly about an inch apart, with the sap sides up-stream, if possible, to avoid abrasion. As they do not have the shock and heavy abrasion that the main sluice-blocks do, green blocks will do very well. After the season is over, they should be carefully burned, however, and the fine adhering gold recovered. Spaces between are made with small wooden wedges or stones laid on the bottom as the blocks are put in. Liners are used as in the main sluices to hold the blocks down. The upper end of the undercurrent is usually slightly fan-shaped, to allow the spread of the water and fine sediment to be regular. This is connected to the main sluice by a 'neck' which is directly under a grizzly near the end of the latter. The direction of the undercurrent flow is usually at right angles to that of the main sluice. The construction of the grizzly and 'neck' is shown in Fig. 2.

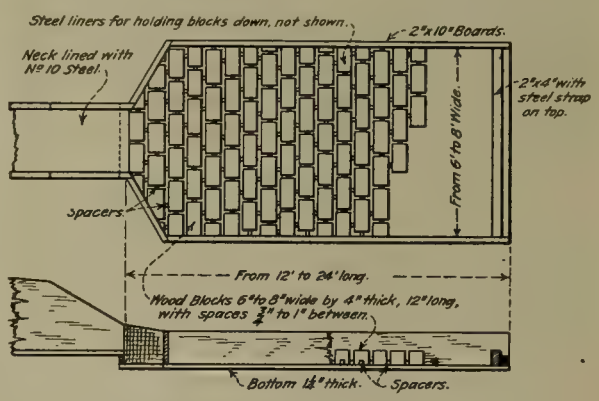
Another type of undercurrent, used in California and Oregon, consists of a box of about the same dimensions, but the riffles are of the plain Hungarian type, being two-by-fours laid in alternate bands lengthwise and crosswise. These two-by-fours are covered with strap iron and spaced 1½ to 2 in. apart by means of wedges between the ends.

Still another type, but one which I have never used myself, does away with riffles altogether. This is used in some of the eastern counties, and consists of strips of brussels carpet laid across the box, tufted up by means of ordinary 'chicken wire' laid on top of it. While this would doubtless hold some of the fine gold, it seems too easily abraded.

The foundation for the undercurrent is often a difficult piece of construction. It is, of course, very poor practice to lay it on the dump, as a rise in the river some night might carry the whole thing out and cause the loss of the best part of the clean-up in some cases. Where the main sluice dumps directly over a bluff into the river, footings should be carefully cut in the bluff and the undercurrent run out at this point.

I have often saved from one-fourth to one-third of the gold in my clean-up in the undercurrent—gold that had passed over a hundred feet of sluice without lodging permanently in the riffles. The average grade for an undercurrent should be slightly steeper than that for a sluice, as the water is much better distributed. From eight to eleven inches in a 12-ft. box is satisfactory.

The 'neck' should be lined with ordinary No. 8 or 10 B.W.G. steel, as the water pouring down through the grizzly exerts a good deal of erosive action. Also, the lip at the end of the box, over which the undercurrent



Steel liners for holding blocks down, not shown.

FIG. 2.

discharges, should have a strap of steel over it. This is usually a two-by-four placed square with the end of the box, in such a way that it can be removed after the water has been turned off and the clean-up completed, to collect what fine amalgam may be lodged under it.

The grizzly in the main sluice is best made of ¾-in. octagonal steel bars, spaced about an inch apart. This allows most of the water to go through and practically all the heavy fine sediment, while the boulders bump over the end of the main sluice from their own momentum. In large mines, however, two or three undercurrents are often spaced at intervals along the main sluice, each one taking its quota of discharge.

The Flotation of Copper Ores

By AN OCCASIONAL CONTRIBUTOR

Introductory.—The work of the past two years at many mills in the United States, Mexico, and South America, has done much to prove the suitability of flotation processes to the recovery of the sulphide ores of copper, and to indicate the best reagents. In a general way, it may be said that oils of mineral origin, such as coal-tar and fuel-oil, give better results on copper ores, while oils of vegetal origin, such as the terpenes, pinenes, wood-tars, etc., are better adapted for the treatment of zinc and lead ores.

Coal-Tar Products.—Among these cresylic and carbolic acids are the best known reagents. Commercial cresylic acid is an oily refractive liquid, generally with a red or yellow tinge, has a specific gravity of about 1.044, and consists of approximately 40% metacresylic, 35% orthocresylic, and 25% paracresylic acids, the properties of these three isomers being, according to Lunge and Keane:[1]

Acid.	B.P.	Solubility in 100 parts water, ordinary temperature.
Orthocresylic	191°	2.50 vol.
Metacresylic	203°	0.53 "
Paracresylic	202°	1.80 "

This acid is much less soluble in water than its homologue, carbolic acid, and is still more easily broken down by sulphuric, which probably accounts for the statement that sulphuric acid may not be used along with either of these weaker acids. My own experiments give conflicting results, and I cannot speak with confidence on this point.

I have found a marked difference in the behavior of different brands of cresylic acid, and I suggest that, in conjunction with tests run, the different brands be analyzed to see what bearing the differing amount of the three constituents has on the action of the various acids. I had very poor success in treating a certain chalcocite ore with a dark colored cresylic acid, and on changing over to a light colored brand, I had immediately surprisingly good results.

Lunge and Keane give a method (Rascheg's) for the estimation of the three isomers of cresylic acid. For the benefit of those who may not have access to this book, I give it in full:

On treating *m*-cresol with excess of HNO_3 at 100° it is quantitatively converted into trinitrocresol, while its isomers are completely oxidized to oxalic acid. The following directions, which must be most carefully observed, give reliable results:* Exactly 10 grammes of the cresol mixture are weighed into a small conical flask mixed with 15 c.c. ordinary H_2SO_4 (1.84), then treated for 1 hour in a steam-oven, and the contents poured into a wide-necked flask of 1 litre capacity. The flask is cooled under the tap, shaking it round meanwhile in such a manner that the sulphonic acid, which is a mobile liquid while hot, settles as a thick syrup on the sides of the flask during cooling. 90 c.c. of HNO_3 (1.38) are then first poured into the small flask in which the sulphonation was conducted, in order to remove any sulphonic acid adhering to its sides, rinsed well round, and then poured, all at once, into the larger flask. The contents of the latter are well shaken immediately, so that all the sulphonic acid is dissolved, which takes about 20 seconds. The flask is then placed in a draught-cupboard. After one minute a violent reaction occurs, red fumes are evolved, and the liquid boils; then it suddenly becomes turbid: oily drops of trinitrocresol form and collect on the bottom of the flask; and after five minutes the reaction is apparently ended. The whole is allowed to stand for at least another five minutes, then poured into a dish containing 40 c.c. water and the flask rinsed out with a further 40 c.c. water into the same dish. On mixing with water the trinitro-*m*-cresol solidifies with liberation of nitrous fumes to a crystalline magma. It is allowed to stand for at least two hours while the liquid cools; then it is crushed with a pestle, and filtered on the pump through a filter that has been tared against another one. The crystals of trinitrocresol are washed with 10 c.c. H_2O, dried at 95 to 100° and weighed. If these instructions are carefully followed, 1.74 gm. of trinitro-*m*-cresol are obtained for each gramme of metacresol present in the mixture whatever the composition of the latter. The presence of even 10% phenol does not diminish the accuracy, as the picric acid that is formed remains in solution, but the method must not be applied to mixtures containing large amounts of phenol. This, however, does not often occur in practice. In such samples the presence of phenol is detected by the B.P. and also by the fact that the nitro compound does not remain solid in the steam-oven at 95 to 100°, but melts, or, at any rate, forms a soft paste. But a cresol that distils for the most part between 190 and 200° and, therefore, contains scarcely any phenol, always yields a pale yellow crystalline mass, the weight of which divided by 1.74 gives the weight to within 1% of the *m*-cresol in the mixture. It may be well to repeat that not less than 90 c.c. of HNO_3 is to be used, and poured all at once into the flask as quickly as possible, a flask having a very wide neck being used.

To determine all three isomers Rascheg separates the *o*-cresol completely by repeated fractional distillation: the distillates being composed roughly of 60% *m*- and 40% *p*-cresol in which the *m*-cresol is determined as above. This operation, however, is entirely beyond the

[1] 'Technical Methods of Chemical Analysis,' 1911.

skill and resource of the average chemist. It is rendered unnecessary from the fact that the three acids mentioned bear a fairly constant ratio, as before stated, in any commercial cresylic acid; from the percentage of meta-cresylic acid formed, the others may be calculated. These three acids can be obtained in a pure state. I suggest a trial of them on a small scale, and I venture the opinion here that the ortho-cresylic acid is the one that does the work.

Cresylic acid should be handled carefully, as it gives rise to painful skin-wounds, and may easily splash into the operator's eyes. It is well to keep a bottle of olive-oil handy as a remedy.

Coal-Tar Cresols.—Cresylic acid is an expensive reagent, costing at least $1.25 per gallon delivered at Western American mills in peace-time. It comes principally from Germany and England. A search for a cheaper substitute has shown that crude coal-tar creosote, which is a by-product of gas-works, blast-furnaces, and gas-producers, is promising. Samples from different sources vary greatly in liquidity and chemical composition (proportion of phenols and cresols present); they well merit investigation. Being generally viscous they emulsify imperfectly, especially in the cold, and while some solvent like pine-oil or cresylic acid can be employed, such solvents are expensive and tend to mask the effect of the original reagent. It is probable that the employment of the more liquid blast-furnace creosotes, with preliminary heating, would be attended with good results.

Carbolic acid (phenol) is a homologue of cresylic acid. It is difficult to distinguish between them, the smell and color being so much alike. Carbolic acid has a solubility varying from 4.83% at 11° to 11.83% at 77° in 100 parts of water. It is easily broken down by sulphuric acid, yielding oxalic acid. It appears to be much less selective than cresylic acid in its action on metallic sulphides, and a slight excess brings over a concentrate high in insoluble matter.

Fuel-Oils.—My investigations cover Mexican, Texan, and Californian crude oils. From the known difference in composition, it is not surprising that on any particular ore the results are widely different. The metallurgist should have samples of all three on hand when running tests. Fuel-oils are not highly selective like cresylic acid, pine oil, etc., but are strongly emulsive; they serve the purpose of giving body and mineral-carrying power to the relatively weak but more selective froths; they are cheap, quickly obtainable, and, when used in moderation, bring over little gangue. It is well to increase their fluidity by steam-jacketting the container from which they are fed to mixing-compartments.

Gas Oil (stove-oil).—This is one of the distillation products of crude oil. It is a strong emulsifying agent, which is, at times, most useful. It is worth a trial in running tests. It must be used in very small quantities.

Crude Wood Turpentine.—This is not the ordinary spirits of turpentine. It is a dark reddish-brown liquid with a pungent smell. On gravity-flow machines I have found it of little use, as its action in slight excess is to bring over gangue freely. As an emulsifier, I much prefer fuel-oil or tar-oil. On machines through which the flow of pulp is maintained by mechanical means, it has been found a valuable reagent for the purpose of controlling the levels of pulp, through its physical action on froths, but this result is achieved at the expense of impure concentrate, unless the agent is used in the strictest moderation.

Pine-Oils, Wood-Tar Oils, Fir-Oils, Wood-Creosotes, Etc.—The destructive distillation of soft woods yields a large number of products, and possible reagents. I have found the oils derived from pine and fir to be more selective on chalcopyrite than on chalcocite ores. Wood-tars and tar-oils are excellent emulsifiers, but it appears that the series in general gives better results on zinc and lead than on copper sulphides. I have found pine-oil used in conjunction with crude sulphuric acid to give excellent recoveries on weathered chalcopyrite ores where cresylic acid had been a complete failure. There may be some significance in the fact that the action of sulphuric acid on terpenes (pine-oils) and phellandrenes (crude eucalyptus-oils) is to give in both cases dipentenes and terpinenes.[2] I mention this, as eucalyptus-oils, which are prohibitive in cost in America, are, I understand, universally used in conjunction with sulphuric acid on zinc and lead ores in Australia.

Applicability of the Process.—T. J. Hoover in the latest edition of his book on flotation[3] repeats the statement made in the first edition, that there is a doubt if chalcocite can be recovered successfully by flotation. This surely is an oversight; no one is more cognizant than Mr. Hoover of the recent work done in flotation, and I have only here to refer to the very high recoveries that have been made on a working scale on chalcocite ores, in Arizona, at several large mills.

Cuprite is considered a difficult mineral to recover by flotation. In the case of one ore that has come under my notice, in which the cuprite occurred as a subsidiary mineral, the saving amounted to a small percentage only, certainly not as much as an efficient slime-table would have recovered. On the silicate and carbonate ores there is probably no appreciable recovery.

Mechanical Side of the Process.—In my opinion, the development of what may be termed pneumatic-flotation processes by Callow, Flynn, Towne, and others, constitutes the most distinct advance of recent years. They consist of a directly and cheaply applied supply of air-bubbles in a finely divided state, to assist in bringing to the surface of the pulp the already prepared sulphides. The agitation is cheaply and easily performed, and is quite subsidiary to the action of aeration discussed above. I have found a shallow trough-agitator, with beaters only partly submerged, quite sufficient. The introduction of a jet of live steam

[2] 'Thorpe's Dictionary of Applied Chemistry,' 1913.

[3] 'Concentrating Ores by Flotation,' 1912.

into the mixing compartment is an advantage. The pulp may flow through the mixing and aeration compartments by gravity at the expense of a trifling loss of head-room. This loss is more than compensated by decreased power and labor costs, and simplicity of working. Finely divided air-bubbles can be directly and perfectly applied through many forms of porous media such as canvas, corundum stones, silica-tiles, sandstone slabs, etc. The mineral particles are seized upon and at once removed as concentrate, without having to be repeatedly subjected to a sort of 'fractional distillation' as in the older systems. It is, in a way, the converse of Elmore's vacuum process, and has the merit of being positive in action and under perfect control. Remarkable results have been shown in the economy of reagents, power, and labor, also in the ease with which such machines can be started after any of those sudden stops incidental to milling operations.

Mineral Industries of Brazil

The following report on the mineral industries of Brazil was prepared by Orville Derby, director of the geological department of the ministry of agriculture:

The iron industry consists of one smelting-furnace with a capacity of about 15 tons per day, situated at Esperança, on the Central railway. The ore used is obtained near Miguel Burnier, on the same line. This plant has recently been reconstructed and enlarged. The company has been operating for over 10 years, and the metal that is produced will find a good demand in Rio de Janeiro and Sao Paulo as soon as it is made in sufficient quantity.

The manganese industry is centred in the municipalities of Ouro Preto and Queluz, both in the state of Minas Geraes, where there are several mines in almost continuous operation. The whole production of these mines is exported, the average yearly output being about 200,000 tons.

The mining of copper, which was first started a few years ago at several points in the state of Rio Grande do Sul, and exports of which attained to 1564 tons of ore, seems at present to be at a standstill. It does not figure at all in the customs returns for 1912.

There is only one coal mine, situated at Sao Jeronymo, in the state of Rio Grande do Sul. For many years this mine has produced a few thousand tons per annum.

Diamonds are found and cut at several places in the states of Minas Geraes, Bahia, Goyaz, Matto Grosso, the districts of Diamantina and Bagagem (Minas Geraes), and the Chapada Diamantina (Bahia) being the most productive. The exports for 1912 were $136,457, but it is certain that the total production was much greater. Carbuncles are found in the Chapada Diamantina (Bahia). Exports from Bahia in 1912 were $47,044.

The mining of semi-precious stones occurs in the district of Ouro Preto (Minas Geraes) for yellow topazes; white, green, and blue topaz, aquamarines, and tourmalines being found in the eastern part of the state of Minas Geraes and the adjoining territory of the state of Bahia. Exports in 1912 were valued at $73,140. Rock crystal is found in the state of Goyaz, Serra dos Crystaes. Exports for 1912 were 45 tons, valued at $30,677. Agates are found in several parts of the state of Rio Grande do Sul. Exports in 1912 were 103 tons, valued at $17,580.

The Mount Elliott Mine, Cloncurry, Queensland

By W. H. CORBOULD

*The Cloncurry copper district covers an area about 200 miles long by 40 miles wide, in the northwest of Queensland, Australia. Unfortunately the mines are widely scattered over this area, there being no large groups of them. The Mount Elliott mine is situated about 70 miles south from the township of Cloncurry, and Mount Oxide mine about 150 miles north of Cloncurry. The district has been known for the past 35 years, and in the early stages a large amount of capital was expended with little to show for it; but within the past four years the railway has been extended from Townsville to Mount Elliott and about 40 miles north of Cloncurry, which has made possible the treatment of the ores of the mines on this extension.

The Mount Elliott company within the past few years has smelted and converted on its mine 169,688 tons of ore for 46,040,960 lb. of blister copper, containing 45,644,480 lb. of copper, 35,642 oz. of gold, and 28,841 oz. of silver, at a cost of about £33 (7.07c. per pound) per ton of blister copper, f.o.b. Townsville. This cost included all development, wages, salaries, general management, office, agency, legal expenses, freight, etc. The gold and silver content would practically pay for freight to Europe, refining, realization, and other charges. The costs of supplies are as follows: firewood, $3.60, coke, $18, mine timber, $12.96, and coal, $14.40 per long ton; explosives: dynamite and gelignite, $12 and blasting gelatine, $15.72 per case.

The orebody of the mine outcrops at the surface for about 200 ft., and lies between two slate walls about 40 ft. apart, having a general underlie down to the 180-ft. level of 20° from the vertical; below that depth the ore channel widens out to represent an inverted funnel. The general strike is northwest at the surface, and corkscrews with depth until at the 500-ft. level the strike is nearly due west. The dip follows the strike, and from the surface to the present deepest level is at an angle of approximately 15° to 20°. The copper occurs in oxidized form from the capping down to the 230-ft. level, where the zone of secondary enrichment is encountered, in which the copper is in the form of friable, altered or sub-sulphides. This zone is from 50 to 180 ft. wide, overlying the primary ores, which consist chiefly of chalcopyrites in hornstone. These continue in depth to the present deepest level, 600 ft. from surface.

*Abstracted from *Bulletin* of the A. I. M. E.

Knowledge and Research

By R. W. RAYMOND

*This notable chapter in the history of one of the most ancient American institutions of learning irresistibly recalls the situation of 1787, the year in which the first charter of what is now the University of Pittsburgh was granted. That was the year of the Convention which framed the Federal Constitution. It was notable also as practically the beginning of two other agencies which, though derided at the time, proved afterward to represent the most potent elements in the cementation of that solid union founded by the Constitution. For it was in 1787 that John Fitch ran his steamboat up and down the Delaware; and it was in 1787 that the fierce discussion of the improvements proposed by Noah Webster may be said to have reached its climax. That controversy resulted in Webster's Dictionary and Webster's Spelling Book, which gave us one language throughout our wide and ever wider domain. Thus the bond of political union established by the Constitution was reinforced by the beginnings of internal transportation and of a common speech, without which the growth of our continental empire would scarcely have been possible.

The wonderful changes effected in personal, social, and national life during the century which ensued, would make an easy theme for any orator who might choose to tell the thrilling history of this particular region alone, beginning with the little group of cabins under the guns of Fort Pitt which constituted Pittsburgh, and tracing the conquest and rapid settlement of the Ohio valley (which was never equaled for revolutionary transformation except by the settlement of California under the special world-excitement caused by the discovery of gold), the development of commerce and industry, the accumulation of wealth, and the concomitant advance in education, culture, and fullness of individual and social life. I shall not rehearse to you this familiar story, but I would point out the significance in such a sweeping torrent of change, of the things that abide.

One of these is Pittsburgh itself. Instinctively recognized, even in our colonial period, as a strategic point, to be defended at all costs, it has remained, through the astounding revolutions of its history, always the centre of power and progress, demonstrating in these later days that the wealth accumulated in the service of man through smoky industries is available for man's service also in the fair fields of science and art.

And another thing that abides is the conviction of the value of knowledge which inspired our grandfathers and possesses us. They founded colleges while they were fighting Indians and leveling forests and devising governments. The progress of the world and the eminence of Pittsburgh in that progress are alike due to science. And we Americans recall with just pride that our fathers always provided for education as a part of their social scheme. It would be absurdly superfluous, in this presence, to explain that the wonderful natural advantages of Pittsburgh would have amounted to nothing without the science which has utilized her fuel and her means of transportation. It is not manual labor alone, but, in a much greater degree, the labor of the educated brain, that creates wealth and constitutes power. And it is a peculiar characteristic of this source of power that no one can foretell the scope and value of its results. We know how many foot-pounds of energy a man or an animal can furnish in a given time; but we cannot prophesy what may be done with that energy if applied, under intelligent guidance, to the utilization of the inexhaustible forces of nature. The assertion that "knowledge is power" is an "act of faith"; but this faith has proved itself a thousand times to be well-founded. No one doubts today that the knowledge we now have is power, and must, therefore, be preserved by transmitting it to each succeeding generation—even were there nothing more to know. But we have learned also that the enlargement of the circle of things known increases the boundary beyond which lie the things yet to be known, and hence we attach a practical value to research. We need not claim for our own time alone this recognition of the importance of research. Let us modestly remember that the things we now know are the results of the research which our fathers encouraged and conducted—nay, more: that their faith in knowledge and inquiry was supported by much less evidence of valuable results than encourages us. In fact, we may be said to walk in this path, no longer by faith, but by actual sight.

Nevertheless, it is unquestionably true that the conception of university education has undergone during the last century, an important change. Even so recently as fifty years ago, when I was a student at German universities, the traditional organization of the four faculties of Theology, Law, Medicine, and Philosophy was still maintained, but 'Philosophy' (originally intended to cover metaphysical subjects) had been gradually made the receptacle of everything that was not theology, law, or medicine—including such trifles as mathematics, languages, literatures, and sciences. And the old satire was still current: "Theology yields a man honor but not bread; law, bread but not honor; medicine, both bread and honor; and philosophy, neither

*Principal address delivered at the dedication of the new building of the Mellon Institute of Industrial Research and School of Specific Industries of the University of Pittsburgh, February 26, 1915.

bread nor honor." Yet already it was becoming evident that in the disparaged department of 'Philosophy' lay the studies which were certain to yield both the bread and the honor of the future.

Today, we care little for the old classification. Our notion of a full university is that of the motto of Ezra Cornell, who founded the one which bears his name, as a place where anyone could receive instruction in anything. Toward this all-comprehensive ideal, which no institution, perhaps, has completely reached, we are all striving. And the strength, the inspiration, the fruitfulness of our development is in the increased emphasis which we lay upon research and the function which we assign to it in the modern scheme of education.

I need not make a distinction here between theoretical and practical research. There used to be a vague and uncertain attempt to divide pure science from applied science. But, in fact, they are inextricably blended. It was Sir William Thomson, afterward Lord Kelvin, the profound student of the nature of matter, the weight and movements of worlds, whose acute genius devised the perfect mariner's compass and constructed the apparatus by which the Atlantic cable was able to transmit intelligible messages—turning industrial failure into triumph. When Thomas Edison was perfecting his great electrical inventions, he went to Ira Remsen, the distinguished teacher of pure science, for the mathematical formulas which determined the dimensions, proportions, and relations of his machines. The researches of Hertz and others into what seemed at first to be a sphere of electrical disturbances beyond the reach of human analysis have led already to the miracles of wireless communication and control—messages signaled, or even simply spoken, across oceans and continents, and boats steered by inaudible commands from the shore.

The difference between knowledge and research is the difference between the expert and the discoverer. An expert is one who knows what has been done or is provisionally established in a given science or art. He can say, with regard to a new discovery or improvement, only whether or not it contradicts or transcends what is generally accepted as the result of previous experience. But the discoverer is a prophet, and, if he has not "spoken presumptuously," his message becomes a new revelation, and a part of the science of his day—or the day after.

It seems but yesterday that I read in the newspaper how Charles Sumner, of Massachusetts, had proposed in the United States Senate an amendment to a pending appropriation bill, granting a considerable sum for the conduct of experiments in sending telegraphic messages without the employment of conducting wires. I was an expert then, and, as an expert, I knew (or thought I knew) that the thing had never been done and, therefore, was impossible. I remember reflecting how easily non-scientific people were carried away by the eloquence of fanatics or charlatans, especially when the schemes proposed were such as all the experts declared to be absurd. The common sense of the United States Senate, taking the same view, rejected the amendment; and it is my impression that the distinguished proposer of it (having, perhaps, introduced it at the request of some sanguine constituent) did not fight very hard for its adoption. It is possible that I recorded my opinion of it at the time with sarcastic humor in the columns of the technical journal of which I was editor. I have made no investigation as to that question; and, indeed, I would rather not know the answer!

At a later period, Le Conte, one of the most eminent scientific authorities in America, and one who, in his own department, and in the general exposition of the philosophy of evolution, was a leader and commander, published an essay demonstrating the theoretical, that is to say, the mathematical and irrevocable, impossibility of the navigation of the air by vehicles heavier than air. Now mathematics, as defined long ago by Benjamin Peirce, is the one science which draws necessary conclusions; but the necessity of its conclusions is simply their relation to its premises. Le Conte's judgment was based on the evidence before him. It was the utterance of Science without the testimony of Research. And already another eminent scientific authority, Langley, long of your university, reinforcing science with research, had devised a flying-machine heavier than air, which is now, I believe, admitted to have furnished the first solution of this problem. True, an accident not due to any unsoundness in Langley's theory and design wrecked his experimental machine, and, perhaps, broke his heart, too. But time has vindicated his fame and has given us another instance of the value of scientific research to industrial progress.

But it must be real research, not merely the cloudy anticipation of things to come. Many years ago, I was visited by a seedy young stranger, who desired my assistance in the form of a loan which would pay his fare to Colorado, where he wished to introduce the use of electricity in metallurgy. Under cross-examination, he explained that he expected to get his electricity, Franklin-fashion, from the clouds, and, having heard that there was a good deal of it up in the Rocky Mountains, he thought Colorado was a good place for his process! If that young man has survived (which I doubt, since he did not look like a future survivor), he is doubtless saying today that he was the real inventor of the whole art of electro-metallurgy! He was a feeble specimen of the host of professional inventors who try to pre-empt territory in realms not yet explored, substituting prophetic intuition for patient and skilful research. These are the prophets who "speak presumptuously." The Book of Deuteronomy, after describing such a prophet, adds "Thou shalt not be afraid of him." Yet, in spite of that encouraging exhortation, we are afraid of him; he hangs as an incubus upon every real inventor whose work has been based upon real research; for research is not fruitful unless it is, or until it is, scientific.

The essential quality of Science is that it is quantitative, while mere invention may be in the beginning

only qualitative. After the great blizzard, more than a quarter of a century ago, a storekeeper in Brooklyn undertook to apply quantitatively the qualitative proposition that heat would melt snow. Having a 16-ft. heap of snow in front of his store and a lot of old boxes in his cellar, he dug in the snow a chamber with a chimney, crammed this stove with pine-wood from the cellar, lit the fire, and looked for the mountain to dissolve in fervent heat. Being a qualitative man, he did not know the difference between temperature and heat-units, or dream of the work he was expecting his little fire to do. When he had burned all his wood, he abandoned his faith in science! Yet there is never a heavy fall of snow in New York but somebody berates the authorities for their stupidity in not thawing it away!

And this brings us to the proposition that real research must itself be based upon scientific knowledge. There is nothing more pitiable than the spectacle of an enthusiast, fancying himself a pioneer, laboriously digging in ground already explored, exhausted, and abandoned by others. My friend Clarence King told me once how he set his heart upon the ascent of a certain high peak in the Sierra. With infinite exertion, and no little peril, he scaled the precipitous mountain-side, and reached at last the summit, only to find there an empty tomato-can and a copy of a newspaper, relics left by a picnic party, which had ascended by an easy trail on the other side of the mountain! A little preliminary research would have saved him from this scientific fiasco.

Moreover, the careful and thorough study of science —that is, of what has been done, and has come to be believed already—will often mightily aid research with significant and invaluable suggestions; for the records of scientific experiment contain many observations which were simply noted *en passant* and left for future explanation. A distinguished electrician once said to me that, notwithstanding the amazing advance of his art, he still found in the old, simple, homely notes of Benjamin Franklin valuable hints and suggestions.

If knowledge and research are thus intimately related, each reinforcing the other, the manner in which they are combined in this institution must be recognized as largely novel and wholly admirable; for effective research requires suitable apparatus, and under apparatus we include books. Moreover, research is promoted by definiteness of object. The man who knows what he is looking for is more likely to make discoveries than he who merely launches into space, hoping to make discoveries through accidental collisions. And again, not only motive and apparatus and previous knowledge, but also the capacity of clear and accurate thinking, must belong to the equipment for useful research; and no man thinks accurately who cannot put his thought into words which will convey it to another man qualified by knowledge to comprehend it. We may feel, but we cannot think, unutterable things. What our patent law requires of an inventor, that his invention shall be so stated as to enable anyone skilled in the existing art to practice it, is equally required of every discoverer, whether he seeks the reward of a patent or the recognition of his fellow men in other ways. He must be able to describe and to define as well as to discover.

But this occasion emphasizes to my thought another principle, perhaps the most fundamental and far-reaching of all. In this dedication of a building erected through the intelligent munificence of private citizens, we have another instance of the method and means by which American institutions of learning, as well as of philanthrophy and religion, have rapidly grown in a single century to proportions rivaling those which ancient origin, cherished traditions, and age-long growth have given to such institutions abroad. The generosity of private citizens, since the beginning of the nineteenth century, has surpassed among us all the endowments bestowed upon science and learning by the governments of Europe in modern times, and its results may challenge a corresponding comparison. Our democratic individualism makes mistakes, no doubt: but so does paternal government. The difference is that the mistakes we make we also correct; while the mistakes of paternalism are likely to lie like a permanent, heavy blight upon progress. It is fashionable in some quarters to decry 'foundations' established by private wealth; but we may challenge the critics to adduce a single instance in which, under our American system, an institution of learning or research thus supported has ever been productive of harm. Knowledge and the opportunity to pursue knowledge are the only gifts that do not pauperize the recipient. Nay, more: under free institutions and in the atmosphere of liberty, the recipient of such bounty inevitably returns it in benefaction to society. Long may it be, ere this gracious, wise, and fruitful American habit of great private endowments yields to the assaults of either the demagogue or the doctrinaire!

Perhaps the chief advantage of numerous private institutions of science and research is to be found in the consequent multiplication of independent students and investigators. The victorious advance of civilization and culture is not an organized conquest, like that of a drilled and equipped army under a single head. It is rather like the free, yet invincible, advance of the forest over denuded areas—each tree sending forth its seeds, wind-blown, each seed fighting its own battle with heat and cold or vigorous competitors, and the victorious survivors constituting the forest of the future. Apart from all considerations of government or statesmanship, I thank God for the numerous separate States of our Union, and for the numerous independent institutions in each State which permit the testing of new propositions in science, industry, politics, sociology, or statesmanship on a working scale not fatally extensive.

TIN PRODUCTION of Mt. Bischoff, Tasmania, in the last half-year amounted to 264,320 lb. from 194 tons of concentrate, reduced from 48,354 tons of ore. The smelter at Launceston also produced 1,433,600 tons of tin on custom account. Owing to the war, operations were considerably curtailed.

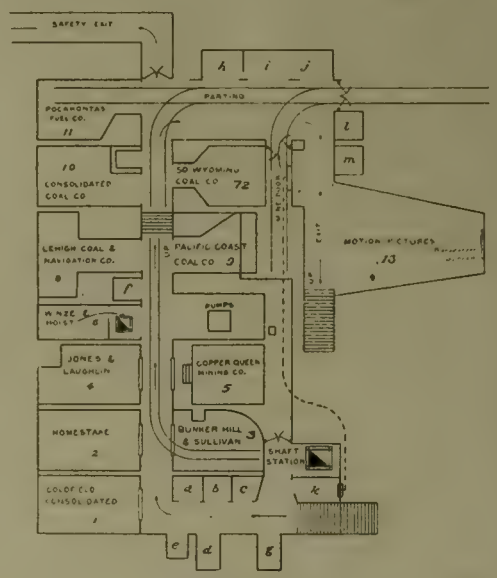
The Mine—An Educational Exhibit

By THE EDITOR

Having seen something of the architectural splendors of the Panama-Pacific Exposition, we went, of course, to the Palace of Mines and Metallurgy, to see The Mine, of which good reports were being passed among our friends. Irvin Cobb, describing the horrors of war, has said recently that it is not the sights but the smell that is characteristic. As the visitor enters the mine he is assailed by the old familiar smell, compact of timber, rock, and damp. It seemed too vivid to be real, so we asked an attendant how it was done, only to learn that it had just happened in the proper way. All the ingredients were there. Indeed, the control of the natural seepage was a difficult problem. The level of The Mine is 15 ft. below the floor of the building, and 6 ft. below high-water mark, San Francisco bay being within a few hundred feet. Two shafts were sunk in quicksand, drains were cut to them, and pumps now work at regular intervals to keep the concrete floor dry, otherwise this underground exhibit would be flooded in a few hours. Great credit is due to those who did this work, especially the U. S. Bureau of Mines, which designed it, and is now operating it with obvious efficiency.

The drift by which we enter becomes an incline; a short cross-cut diverts us into a sub-level leading to the shaft, where a cage hangs expectant. As the engineer apparently has gone to his dinner, we must descend by the ladder, which is alongside, or retrace our steps and proceed down the incline. We do so. The rock through which we pass is not convincing; it is the usual plaster imitation; but it will deceive the tourist. In small chambers to one side are exhibits of Concordia storage-battery electric lamps and Koehler naphtha lamps for the coal-miner; while the metal miner is offered Simmons acetylene lamps. The last mentioned have a cerium igniter, rendering matches unnecessary. A little farther, on the opposite side, is a typical underground powder-magazine, containing cases marked with the Hercules company's familiar name. Dummy sticks of dynamite with imitation fuse attached are shown. The universal danger sign—a red disc on a white plaque—is attached to the timber adjoining. This may be one of the reasons why most of the visitors, particularly the women, seem in an anxious hurry.

Then we come to a reproduction of a stope in the Goldfield Consolidated mine, the famous bonanza in Nevada. The square-set timbering looks natural; so do the Ingersoll-Rand drill and the Waugh stoper. The broken ore is real; it was brought from Nevada. The face of the stope is made out of pieces of rock that have been joined with mortar and then painted. The result is not as convincing as it might be, but it will deceive any non-technical visitor. The timbering and lagging are the real thing, and the rush of air from a 4-in. pipe leading from a Sirocco blower gives a sound that joins with the smell in perfecting the illusion. The Goldfield Consolidated mine includes the Mohawk, Combination, and other claims that were famous during the exciting days of 1906 and 1907. In that part of Nevada, gold is found associated with quartz and alunite in a zone of multiple fracture traversing Tertiary andesites. In places, the lode-channel is 500 ft. wide. On February 9, 1907, one carload of ore, weighing 48 tons, had a gross value of $591,-637; the express charges were $8800; and the check paid by the smelting company, after deducting freight and



MAP OF THE MINE

treatment, amounted to $574,958. During 1914 this mine produced 338,192 tons, having a gross value of $4,340,786, out of which a profit of $1,835,224 was made, permitting the distribution of $1,067,744 in dividends. To the end of last year—seven years in all—the Consolidated has paid $27,398,215 in dividends, or $7.70 per $10 share. The total gross output of the property, including that made by lessees in the early days, has been 2,111,054 tons having a gross value of $63,658,088 or $30.15 per ton. The present manager is Mr. J. W. Hutchinson.

Next we come to a bit of the Bunker Hill & Sullivan mine. The attendant informs us that this mine is entered by an adit or tunnel 10,000 ft. long before it strikes the orebody. From this level it is 1000 ft. to the surface and 500 ft. to the bottom workings. It is the largest lead-producer in the world, the annual production being 36,000 tons of lead, containing 1,200,000 oz. silver. The

miners work on the day shift only, and as they break 1400 tons of ore per day, it is evident that the workings must be numerous and extensive. The ore averages 10% lead and 4 oz. silver before it is concentrated in a big mill. On the track is shown a Baldwin-Westinghouse storage-battery electric locomotive with two cars, loaded with ore

A POWDER-MAGAZINE.

that looks decidedly super-grade. In the real mine this locomotive pulls 17 cars of 5 tons each. At this exhibit the face of the stope is extraordinarily well done, the pieces of rock and ore are so joined that the artificiality is entirely obscured. After the material was in place, it took a month to obliterate the joints. Now it would deceive even an old miner from the Coeur d'Alene. A moil dropped by a careless worker hangs between the lagging overhead and completes the verisimilitude. A Waugh drill ready for use is exhibited, with armored hose. In 1914 the Bunker Hill & Sullivan Mining & Concentrating Co. treated 440,819 tons, having a gross value of $3,362,498, from which $981,000 was paid in dividends. The property represents a consolidation of many claims, the first of which was located in September 1885. Up to the end of last year this mine had yielded 6,462,367 tons, having a gross value of $60,231,542, from which the shareholders had received $15,710,250 in dividends. The manager is Mr. Stanly A. Easton. The ore consists of silver-bearing galena enriching the cracks and fissures of a pre-Cambrian quartzite that has been crumpled and crushed by geologic movement. The silver is associated with the lead in a fairly constant ratio of 1 ounce of silver to 50 pounds of lead. A portion of the concentrate is shipped to the Selby smelter, on the Bay of San Francisco.

Across the main gangway is the exhibit of the Homestake Mining Company. This takes the form of a model illustrating the system of stoping employed in that great gold mine in South Dakota. Three levels are shown, enough to indicate several phases of the shrinkage method. The attendant informs us that excavation begins at the back of the level; as the lode is stoped overhead, the men stand on the broken ore, rising slowly to the level overhead. A timbered passage or manway is maintained so as to give access to the rising stope, and for ventilation. These manways are placed 50 feet apart where the lode is wide. If the ground above is solid, the stope is continued to the level; but if stopes extend above the upper level, then the shrinkage stope is stopped 35 ft. below, the arch thus left being removed at a later stage. Thus the ore between two levels is broken, but not removed, until the operation is completed. Then it is withdrawn at the bottom, the weight pushing downward, so that the small stuff can be shoveled into cars while the big lumps are

A STOPE FROM GOLDFIELD.

drilled and blasted. These shrinkage-stopes are 60 ft. long and are separated by pillars or intervening blocks 42 ft. long, the width being that of the lode, which ranges from 50 to 200 ft. between walls. The pillars are removed by aid of square-set timbering in the usual way. Incidentally, Philip Deidesheimer, who invented this method of timbering on the Comstock in

1860, is still alive, a resident of San Francisco. The model also shows the method of filling old stopes, the waste from one of the big open-cuts being run into the mine by gravity and then distributed as required. The 'filling' and the ore used in the model are both made of the real stuff. Of the ore yielded by the Homestake 25% is mined by square-sets and 75% by the shrinkage system; 2,000,000 tons of broken ore is said to be stored underground. We were also informed that the mine had 30 years of ore in reserve, to which we may add that the last official report states only that the reserves represent "many years' supply" of ore. In the life of a mine, 30 years is more than 'many.' Upon an adjoining table are large specimens of the ore and of the principal minerals. On a chart the analyses of the rocks and minerals are given. The exhibit is excellent, and is rendered more generally useful by the explanations of the attendant. Official records show that the output of gold in 1914 was worth $6,160,161 from 1,587,774 tons. The average was $3.879 per ton; the cost is not given exactly, but it was about $2.50 per ton. Extraction represents 94% of the gold contents of the ore. In 1914 a sum of $2,210,208 was distributed in dividends. To the end of the year this mine, including the smaller companies absorbed, had produced $134,181,596 and paid $33,405,700 in dividends. The Homestake lode is a mineralized gold-bearing zone in schist of pre-Cambrian age, where it is penetrated by intrusions of post-Cretaceous rhyolite. In 1914 Mr. Richard Blackstone succeeded the late Thomas J. Grier as manager.

I have remarked that some of the visitors seem in a hurry, as if intimidated. Perhaps the dynamite, the danger-signal, and the mine-car with its head-light ready to move, are the causes. Not many of them ask questions and even those that do so seem to be half-hearted. Occasionally an intelligent observer comes along and catechises the attendant, who is then in his element. Undoubtedly the value of an exhibit is multiplied many times by furnishing an intelligent explanation of its use. The day of prune horses and pyramids of oranges is gone. If expositions are to recur, they must be more than exaggerated county-fairs. In this Exposition, the finest exhibit, because it is the most immediately instructive, is the working model of the Panama Canal. Next in merit is The Mine.

Proceeding, we come to a sample of the Copper Queen, the famous mine near Bisbee, in Arizona. The section of the lode, with its foot-wall, has been reconstructed with remarkable fidelity. On the posts of the square-sets the average assay is chalked in percentages of copper —7, 14, and 15.5%. A dinner-bucket and a jumper hang on a nail in the corner of the innermost square-set, and in the pocket of the jumper is a copy of the Bisbee *Daily Record*. Our compliments to our contemporary in Arizona. A ladder-way and timber-pass complete this underground picture. Various types of lode-matter are exhibited in the forms of slabs, 1½ by 4 ft., in glass frames. Both here and in the Homestake exhibit we noted an error in the labels, not important, but likely to confuse the uninitiated. The Copper Queen is one of an important group of mines controlled by Phelps, Dodge & Co., of New York. The manager is Mr. S. W. French. In 1914 the tonnage treated was 654,669, from which 76,842,974 lb. copper was extracted, besides 627,612 oz. silver and 14,875 oz. gold. Production was curtailed during the last four months, by reason of the depressed metal market. During the first six months the output of copper was 50,000,000 lb. The company owns subsidiary mines, notably the Moctezuma, bringing the total production to 732,829 tons yielding 86,066,143 lb. copper, 8,889,175 lb. lead, 1,936,677 oz. silver, and 15,769 oz. gold. The total copper output made by the constituent companies controlled by Phelps, Dodge & Co. in 1914 was 140,231,384, of which 8,569,060 came from ore smelted for the Miami company. Dividends of $6,300,000 were paid during that year. The mine was first opened in 1880, on an outcrop of oxidized copper ore in massive limestone. The orebodies occur in large masses at the base of Carboniferous limestone where it is broken by extensive dikes.

Across the gangway is the Lincoln mine, an example of the iron mines of the Mesabi range, in Minnesota. Round timbers and split lagging are in evidence, with the characteristic hematite ore in the face and broken on the ground. The tools, track, and stray sticks of timber are useful accessories.

Next is a chamber marked 'Winze,' which our friend, Mr. R. Arthur Thomas, the manager of the celebrated Cornish tin mine, Dolcoath, would call 'winds,' for that is the ancient spelling of the word. In the cross-cut several Waugh drills are ready for use; also a Westinghouse electrically-driven centrifugal pump and the Leadville drill-column hoist made by Hendrie & Bolthoff, Denver. This last must be a most handy machine. Opposite is a Byron-Jackson pump and an air-compressor furnished by the General Machinery & Supply Co. of San Francisco. An underground primer-room comes next; it is furnished by the Coast Manufacturing & Supply Co., of Livermore, California, and contains a fuse-cutter, with instructions for adjusting safety-caps and using a crimper.

Then the visitor comes to a room simulating the anthracite mines of the Lehigh Coal & Navigation Co. at Lansford, Pennsylvania, showing the thick vertical seam of anthracite, which lends itself to almost ideal mining conditions, and surprises the visitor, who is apt to visualize coal mines as consisting of almost horizontal workings. Apparently coal is easy to simulate by the liberal use of P. & B. paint. It is interesting to note that anthracite coal was discovered in the Wyoming valley by Connecticut settlers in 1762; in 1782 some of it was sent to Philadelphia, but, finding no sale, was used in gravel walks; in 1820 the output was 365 tons; in 1914, 91,448,000 tons.

Across the gangway is a sample of a different type, a representation of the Pacific Coal Company's mine, at Coal Creek, Washington, where a thinner inclined seam of bituminous coal is mined with Sullivan punchers and

Ingersoll-Rand shearing-machines. Adjoining it is a room, equipped by the Southern Wyoming Coal Operators Association, showing the gently-dipping seam of sub-bituminous coal at the Rock Springs mine, which furnishes fuel for the Wyoming division of the Union Pacific railroad. A room representing typical workings of the Consolidation Coal Co. in the Elkhorn coalfield, at Jenkins, Kentucky, contains various other pieces of equipment, including an auger, used in boring holes for blasting. By such machines the arduous labor of the miner is much ameliorated, more coal is produced in marketable form, and the cost of labor is decreased. It is interesting to note that Kentucky produces two-thirds of all the cannel coal of the United States. This variety of bituminous coal burns so freely that when a small piece is ignited it will continue to burn like a candle, whence the name. Finally, we come to a room representing the famous Pocahontas mine of the Pocahontas Consolidated Colliers Co. The Pocahontas and New River fields of West Virginia are really one, the Pocahontas seam being identical with the Quinnemont of the New River, the coal area being 60 miles long by 16 wide, or five times the size of the Connellsville. Pocahontas coal is remarkable for being smokeless, and this, coupled with its high calorific power and freedom from ash, has made it the best fuel for naval purposes, where a trail of smoke is a signal to the enemy. For this reason the Pocahontas seam has held significant place in national economy, though the growing use of petroleum as a naval fuel has lately tended to decrease its importance.

A mine-telephone plant is exhibited by the Western Electric Company. Several examples of the Canton mine-door are shown, and operated. They ensure automatic opening and closing as cars approach or depart; they also prevent interference with the ventilation. Finally we come to the office of a shift-boss as arranged by the *Mining and Scientific Press*. It contains a stope-board with other records; a Johnson's First Aid cabinet and candle-boxes containing lamps and books, the one to guide the legs and the other the mind of the shift-boss. A mine transit is lent by A. Lietz & Co. In a cross-cut we find moving pictures in action, illustrating sundry phases of mining. While we lingered, we saw drill-holes at the Nevada Consolidated Copper mine, at Ely, being loaded and then exploded with great effect.

A BIT OF THE COEUR D'ALENE.

THE HOMESTAKE EXHIBIT.

To make the mine appear thoroughly realistic, a genuine explosion takes place each day at 2 p.m., when the rescue crew, equipped with oxygen apparatus descends into the mine, brings out a victim, and then proceeds to restore animation by standard methods. This is the finishing touch to an exhibit that deserves sincere praise. It is educative and informing. Those unacquainted with mining have their curiosity awakened to good purpose and go away with some understanding of a great industry; those that are not novices will find their memory and intelligence pleasantly stimulated.

Air-Blasts

Visitors to Houghton and Hancock, in the Michigan copper region, are often startled by a sudden trembling of the earth, a rattling of windows, and a feeling of instability underfoot. Very often the first shock is followed a few minutes later by a second. The effect upon the visitor is similar to that of a series of earthquake shocks. When, in a startled voice, he expresses a desire to know the cause of such disturbance, he is informed that it is nothing but "an air-blast at the Quincy." It is generally known that these air-blasts occur in some of the deep mines, but it is not realized by many what the consequences of these movements are. Since mining operations in most districts are not carried on at such great depths as in the Michigan copper district, it might be interesting to engineers elsewhere to know the effects of a series of recent air-blasts in the Quincy mine, at Hancock. The general manager, Charles L. Lawton, in his report for the year 1914, writes as follows:

On March 25, air-blasts occurred throughout the mine and continued intermittently for a week or ten days. As a consequence, various cross-cuts and drifts were crushed and closed up. No. 6 shaft-timbers were seriously crushed between the 51st and 58th levels, and No. 2 shaft was crushed and closed between the 40th and 50th levels.

About 500 ft. of the crushed section of No. 2 shaft had to be entirely recovered and re-timbered at an expense nearly as great as that of sinking a new shaft. In the remaining portion of the damaged shaft, about half of the timbers were replaced. Excellent work was done, and a speed record made in recovering the shaft in the months of April, May, and June.

Below the 50th level, the shaft was not damaged by the air-blasts, though the cross-cuts at the 57th, 64th, 65th, and 66th levels were entirely closed, and the levels north were badly crushed. The 67th, 68th, 69th, 70th, and 71st levels north and south were not injured. The shaft has been entirely repaired and is now in good physical condition.

It was necessary to employ a considerable force of men for several months to renew and repair a large proportion of the timbers in the crushed section of No. 6 shaft, and to strengthen it by filling the old adjacent stopes with rock, while keeping the shaft in constant operation, in re-opening cross-cuts and drifts that were crushed, and in re-opening and re-timbering No. 2 shaft. Thus the cost of production was increased very much during the month following the air-blasts, especially because of the loss of three months' product from No. 2 shaft, and consequently the impossibility of operating the mine, railroad, and stamp-mills as economically at about 65% capacity.

In earlier days, when air-blasts were little understood, it was the custom to stope-out the lode irrespective of the shaft. If the lode was rich in copper, it was stoped-out close over or under the shaft; where the shaft was in the lode, the latter was stoped right up to the shaft without leaving shaft-pillars. Going through the upper portions of No. 2 and No. 6 shafts, is like going down through open stopes, with practically no pillars left to protect the shafts. It was in the lower part of these sections that the caving and crushing took place, with such serious results.

For several years there has been a rigid adherence to the policy of leaving increasingly larger shaft-pillars as the shafts are sunk, in order to sustain the litho-static pressure about the shafts. The air-blasts have never caused any damage to these sections of the shafts. At the present bottom of the mine, these pillars are being left 200 ft. each side of the shaft.

Air-blasts have continued with more or less frequency since July, though they have not damaged or retarded the work to any great extent. There were but three fatal accidents during the year, involving less than one-fourth of 1% of the working force.

In order to meet the air-blasts and prevent as far as possible the damages caused by them, as fast as the mining in each stope is finished, the bottom of the stope along the back of the level is filled with poor rock, constituting what is termed 'rib work.' Experience has taught that these rock-packs are the most effective means yet employed to lessen the damage caused by air-blasts.

After a careful investigation and study of the effects of the series of air-blasts that occurred in 1906, rib-work was employed for the first time throughout what were then the lower workings of the mine to combat the damages caused by these disturbances. For a number of years these rock-packs proved effective, until the series of 1909. Again careful investigation and study readily showed that the rib-work was along proper lines, but had not been carried far enough. Therefore the packs were made deeper in the stopes, that is, doubled in size. For a still longer period of time these rock-packs proved sufficient, until March 25, 1914, when another series of air-blasts occurred. For the third time it has been shown that the rock-packs proved to be the best means of limiting such damage.

In order, however, that the highest effectiveness possible may be secured within the limits of profitable mining at greater depth, this rib-work should be still further strengthened. It is estimated that the voids in the rock give it a shrinkage of about 20% at the present depth of the mine. In order to lessen this shrinkage and strengthen the rib-work, the question of filling the voids with bank-sand, stamp-sand, or crushed rock is receiving serious consideration, inasmuch as provision must be made for better and stronger supports to the back of each level, as fast as stoping is finished. This must be done so as to avoid extended crushing, and thus guard the safety of the employees, minimize the losses and expenses caused by air-blasts, and make permanent the mine's future operations with depth.

During the year, $57,190 was spent for the recovery of the shafts and levels that were damaged by the air-blasts, and $21,487 has been expended in the fight toward preventing damages by air-blasts.

The Kennedy Dam

By JOHN S. EASTWOOD

Dams are used for a greater variety of purposes than most people think. Each of the multiple-arched dams designed and built by the writer to date has been intended for a different service. The Hume Lake dam was built for the storage of water for transporting lumber in a flume and as a logging-pond for the storage of logs for the saw-mills of the Hume-Bennett Lumber Co. at Hume, Fresno county, California. The new Big Bear Valley dam was built to store the excess waters for a series of years, from the drainage-area of Bear creek, as a reserve supply for the intensive irrigation of the citrus groves of Redlands and vicinity. Incidentally, the water is used also for power, on its way from the reservoir to the distribution system.

DAM FOR STORING TAILING FROM THE KENNEDY STAMP-MILL.

The Los Verjels dam is used to store the annual winter flood-waters of Dry creek, a branch of the Yuba river, in Butte county, California, for the irrigation of the olive lands of the Los Verjels Land & Water Co. The Kennedy dam, described in this article, is used for storing the tailing from the stamp-mill of the Kennedy Mining & Milling Co., near Jackson, Amador county, California. Thus, of four dams of the multiple-arched type, now in service, one is used for log and water storage, one for cyclic irrigation water storage, one for seasonal irrigation water storage, and the last for the storage of stamp-mill tailing. The structure erected for the Kennedy company is a multiple-arched dam, especially designed to meet the conditions at the site selected and for the purpose of storing tailing. The computations of loads and stresses are based on the assumption of a liquid load averaging 75 lb. per cubic foot. The tailing, when thin enough to exert complete hydrostatic pressure, will not weigh this much, and before it reaches this density will have become so viscous as to exert a pressure limited by the angle of repose that it will assume as in the case of dryer materials. Practically, the greatest pressure that can be exerted on a débris dam is that due to the full hydrostatic pressure of water; for as soon as the débris begins to settle to the bottom, the pressure will decrease until the dam is merely a retaining wall for a material having a large angle of repose and a consequent loading less than the hydrostatic water load with the full dam. This seems like a paradox, but on closer scanning it will be seen that the angle of repose of the fill increases as fast as or faster than its weight.

The structure is situated about one-half mile north of the town of Jackson, on the property of the Kennedy Mining & Milling Co., and closes the lower end of a small valley. The dam is 30 ft. high from the ground-surface, and forms the base of a structure to be eventually built to a height of 50 ft. The storage-capacity, on the basis of the horizontal contour space enclosed, is 15,804,164 cu. ft., up to the 50-ft. contour, but as the sand and coarser materials lie on an angle of repose varying with their size of particle, usually above 20° from the horizontal, the actual capacity is much greater than this, as the flume carrying the slime from the lifting-wheels enters the upper end of the valley at an elevation considerably above the 50-

ft. contour, and it is therefore possible to utilize the slopes of the valley for disposing of a large amount of the coarser sand. The drainage-area of the whole valley is but 0.13 square mile, and the rainfall not excessive, requiring a very small spillway-capacity at the dam.

The dam is 455 ft. long on the crest; it consists of 11 arches and 12 supporting buttresses, and a small spillway having a 15-ft. opening, placed at the west end of the structure. The span from centre to centre of buttresses is 40 ft.; the slope of the water-face is 10 horizontal to 12 vertical; the slope of the back edges of the buttresses, which are stepped to make the connections for future extension, averages ½ to 1; the angle of arc of the extrados of the arches is 133° 34′; the radius of the extrados of the arches is 21.8 ft.; the radius of the intrados is varied to give the required thickness of arch-ring. The minimum thickness of the arches is 1 ft. at the top, and of the buttresses the same. The buttresses are supported laterally by means of a strut-tie beam running through from end to end and terminating in a counterfort, thus making the buttresses the equivalent of short columns and preventing any lateral vibration. The spillway is situated at the west end of the dam so as to deliver the water to the most convenient point for use for irrigation, and is 15 ft. wide and 2 ft. deep, being provided with flashboards to regulate the flow of the water and to carry it up to the top of the dam.

The country rock is slate, pitching toward the east at a steep angle, and striking almost across the axis of the dam. This bedrock is here overlain by a clay to depths varying from 4 to 20 ft., merging into sound slate as the depth increases, the upper portions being merged into the clay. For the most of the foundation it was necessary to go down only about 6 ft.; but in the trough of the valley it was necessary to go down 20 ft. in one place. In all cases the excavations for foundations were carried down to firm bedrock and the footings of the walls spread to the full width of the trenches, giving a very light base-loading, the maximum in any case being less than 5 tons per square foot. As the arch is a free arch, that is to say, three-hinged, all of the load is assumed to be carried on the buttress-bases. The toe or base of the arch-rings is placed in a tapered trench excavated in the bedrock and the trench filled up to the rock-surface without forms, making a cut-off wall, the wall above the bed-rock-surface being allowed to spread over the top of the rock on the up-stream side, the forms meeting the trench on the down-stream side.

Wooden forms were used throughout except for the hinge-sockets, those for the buttresses being made in panels, using inch boards nailed on 2 by 4 studs framed, the panels being three kinds, angle-panels for the buttress-fronts, full panels for the main walls, and half-panels for finishing the rear ends of the buttresses. The full panels were 4.8 by 8 ft., the angle-panels and half-panels being 4 ft. long, all so planned as to permit of their being fastened to the next by means of dowel-pins of wood, and the panels so arranged as to break joints with each other.

The front edges of the buttresses are made in the form of a corbel, the corbel containing the spring-line hinge-socket of the arch-ring, which was cast by means of a metal form, rolled to the true curvature, the remaining parts of the corbel-forms being made of wood. The forms for the intrados of the arch-rings were made of wood, following the original method used in other dams of this type, these consisting of liners built up of inch boards with 2 by 4 studs nailed between, the whole being covered by ½ by 6-in. boards nailed to the studs and lapped.

The forms for the extrados of the arches consist of panels of such a size that four make up the segment of the exposed arc, the panels being of liners of 1-in. boards cut to the curvature, with narrow boards nailed across, all panels being so designed as to be fastened to each other by means of dowel-pins through the frames.

By the use of a three-hinged arch, all bending in the arch-ring is eliminated, but in order to prevent the possibility of cracks in the arch-rings, old cables were used for reinforcing the arch-ring segments. These are placed on the line normal to the arch-crown line and wired in place one foot apart, being cut to a length to suit the segment. At the spring-line hinge-socket in the corbel a hooping effect was obtained by placing ½-in. twisted rods at a depth of 4 in. below the surface running around the entire corbel and into the buttresses. Short pieces of ¾-in. twisted steel are inserted in the stepped back of the buttresses to tie them to the extension when made, at the time of adding the remaining 20 ft. of top for which the design provides. The strut-tie beams are reinforced as continuous beams with five old hoist-cables, 1¼ in. diameter, these running the full length of the beam and into the counterfort at the end of the beams. All cables were left with their grease coating intact and were wired in place.

The concrete was specified to be of a mix of 1:2:4 for the arch-rings and of a 1:2½:5 for the buttresses, but in fact was richer than this in all cases. The aggregate was obtained from the old placer diggings in the upper end of the valley, and is made up of irregular fragments of quartz-rock of varying sizes intermixed with slate fragments. In its natural state it was so dirty that it was necessary to wash it before using. A gravel-washer was installed, all of the gravel and sand being washed and screened before being used.

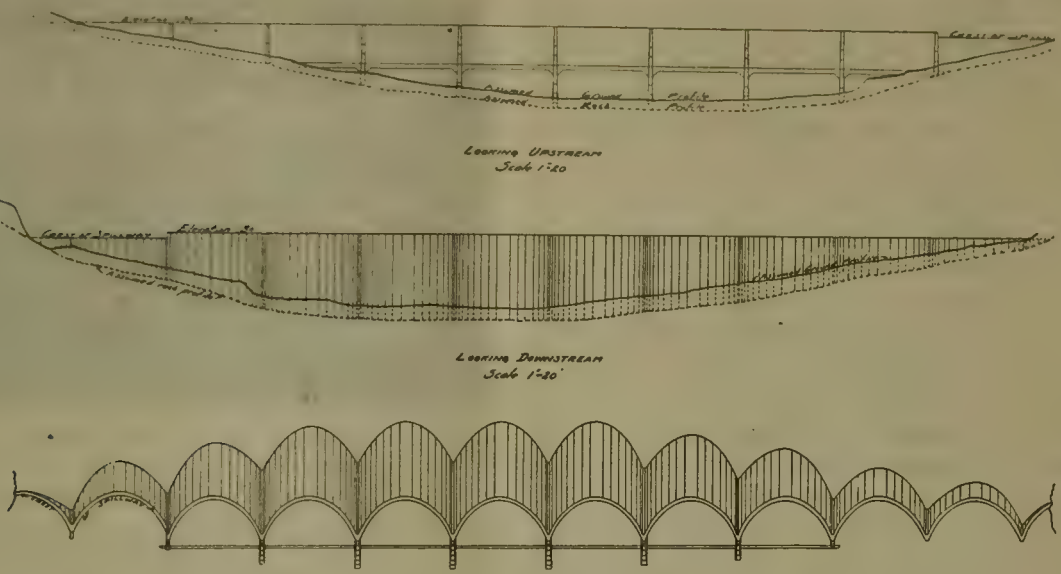
The gravel from the pit was hauled into a stock-pile and was scraped into the boot of a bucket-elevator by which it was hoisted to the top of the washer-tank and dumped into the water, being forced slowly up an inclined wooden tank through the water and finally delivered into the end of a conical screen through a spout, the fine material dropping into a bin

under the screen and the coarse into a separate bin. Water was forced through the end bearing into the tank, and also through perforated pipes lying alongside the screw. This type of washer did not work well with the irregular coarse aggregate, as it would jam under the screw and stop it, requiring a lot of work to find and remove the offending piece, which was usually a flat spall that got under the blade of a screw-flight. The separated aggregates were measured in chutes in the proper proportions from the bins and mixed in a Lansing mixer, operated by a gas-engine.

The buttresses were carried up first and finished to the full height, after which the arch-rings were poured, keeping them all at about the same level. The arch-rings were poured in alternate halves for a small height, using a part of the corbel-hinge form for the crown-hinge form, which was slipped up about half its length on a line and the concrete laid against the finished part. The metal forms used for the hinge-sockets made smooth work except that an occasional small stone pocket would occur, in which case the holes would be filled with mortar, screened smooth and troweled, and when dry a coating of asphaltum was applied to the surface with a flat brush, the excess being removed by using a hot hand-roller for burnishing the surface. When finished, an even and polished surface of asphaltum was shown, this being the form against which the arch-ring was cast. Care was used not to abrade this surface, the concrete being tamped against it by means of puddling with sticks.

The dimensions and stresses in this design were carefully checked, and the plans for the dam approved by Col. W. H. Heuer, U.S.A., of San Francisco. The approval of this type for storage of débris was only given after a very thorough analysis of the stresses in the design and the suitability of this type of structure for the purpose. The multiple-arched dam is the ideal dam for the storage of débris; without doubt it is at once the cheapest as well as the strongest permanent dam that it is possible to devise. Cost plays such a prominent part in the problem that it is almost always the determining factor; for upon cost depends the possibility of the development of a project with profit. There are many hydraulic mining properties in California that are tied up on account of the cost of the storage of the débris, using the type of archaic dam specified by the authorities in charge. The difference in the cost of the types of dams means the difference between the possibility of development and the abandonment of the project for all time.

Work was commenced on the dam, June 10, 1914, and the structure was completed December 1, 1914. The work was done by the Eastwood Construction Co. on the basis of cost plus a fixed sum for engineering and superintendence. The opening in the base of the dam was closed on December 4, 1914, and the pond was full of water up to within 10 ft. of the top on December 17, 1914.



PLAN AND PROFILE OF DAM.

SUMMARY OF DATA

Length of crest	455 ft.
Height above surface	30 ft.
Height above foundations	43.8 ft.
Length of spans	40 ft.
Number of buttresses	11
Number of arches	12
Arc of extrados	133°34′
Radius of extrados	21.8 ft.
Maximum loading	18.85 tons per sq. ft.
Minimum safety-factor	10
Base-loading on buttresses	5 tons per sq. ft.
Cubic yards of concrete	1233
Ratio of cost to that of solid dam	25.2% or as 1 to 3.99
Ratio of yardage to that of solid dam	1 to 6.92

Australian Ores and Metals at the Exposition

In its business-like exhibit of products from the two primary industries of the Commonwealth, namely, agriculture and mining, Australia has a valuable and interesting display of ores and metals. Owing to the War the scope of the general exhibit was considerably reduced and, excepting a few items from Victoria, the states of New South Wales and Queensland occupy the building. This does not detract from what is to be seen, as the minerals of these states are more varied than those from the others. The following notes deal with the New South Wales display:

GOLD.—The gold output of the state to the end of 1913 totaled 14,148,432 oz. The Cobar district is the most important producer of this metal. Exhibits are shown from the Mt. Boppy, Occidental, and Cobar mines. From the Wyalong district are ores from the True Blue, Golden Fleece, and Barrier. Other ores are from properties in the Adelong, Currajong, Lyndhurst, Peak Hill, and other smaller areas.

SILVER-LEAD-ZINC.—Although there are several silver-producing districts, the Broken Hill district is by far the most important. In 1913 the State produced 14,504,889 oz. As silver, lead, and zinc are so closely allied they will be discussed together. Broken Hill has produced metals worth £73,000,000 to the end of 1913, of which £16,177,580 has been paid to shareholders as dividends. An excellent lot of exhibits is shown by the Broken Hill Proprietary (£40,291,900 to date), Sulphide Corporation, Junction North, British, North, Block 10, South, and Zinc Corporation. To those who are interested in flotation processes the mill products of the last-named concern are of special interest. Among the exhibits is an instructive model of the Broken Hill lode. It is 13 ft. long, and represents a length of three miles of workings and its value may be understood when it is said that the model shows the lode in three dimensions at a glance. The R. Broadbent collection of rare minerals from the lode is of great value. These specimens are unobtainable now. Several other districts have sent ores.

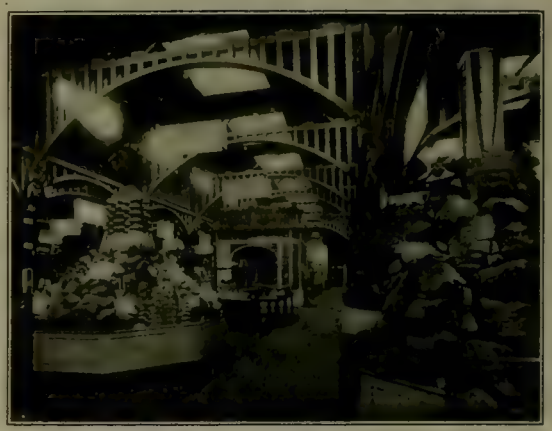
COPPER.—The output of this metal in New South Wales to the end of 1913 was worth £12,382,835. In most of the districts work has been intermittent, owing to the price of the metal. Cobar is the most important and has an output of 235,200,000 lb., 525,000 oz. gold, and 1,500,000 oz. silver. Among the exhibitors from the State are the Great Cobar, Chesney, Gladstone, C. S. A., Burraga, Grafton, Cadia, Mt. Jasper, and three tons of copper ingots from the Electrolytic Refining & Smelting Co.'s works at Port Kembla.

TIN.—The output to 1914 totaled £9,748,901, principally from the New England districts. Lode material, tin 'wash,' stream tin, and ingots are exhibited, the last from the Sydney Tin Smelting Company.

IRON.—Iron ore reserves are estimated at 59,317,000 tons. Iron products manufactured in 1913 amounted to 46,536 tons. The new plant at Newcastle will greatly augment this quantity. The Esbank iron works exhibits ores, fluxes, and coke; pig iron and various shapes. The Cadia-Iron Duke mine sent hematite, limonite, and magnetite.

COAL.—The coal reserves of New South Wales are estimated to contain 115,300,000,000 tons in the four great fields, of which Newcastle is the most important. In 1913 the output was 10,414,165 tons. There are 115 mines operated, employing 18,966 men. Several large cubes of coal draw attention to this part of the exhibit.

KEROSENE SHALE.—Large reserves of this valuable source of oil occur in this state. It contains from 60 to



VIEW IN THE AUSTRALIAN BUILDING AT THE EXPOSITION, SHOWING PART OF MINERAL DISPLAY. LEAD, SPELTER, AND TIN ON THE LEFT, GEM CASES IN THE CENTRE, AND COPPER ON THE RIGHT.

120 gal. of crude oil per ton, against 20 to 30 gal. in the Scotch shales. The output of 1914 totaled 1,668,419 tons. Shale from the Commonwealth Oil Corporation's deposits is exhibited in large blocks.

Other small, but rarer and valuable exhibits, include tungsten ores, molybdenite (this occurring in certain silicious granites, near their contacts with other rocks, in the form of pipes or chimneys), manganese, chrome iron ore, mercury ore (cinnabar), platinum, magnesite, alunite, limestone, and cement (value of cement in 1913 was £402,249, and is making great increases), building stones (cubes and turned pillars), and antimony. The last mentioned ore is of common occurrence in New South Wales, and at Hillgrove contains gold. The output to 1913 totaled 16,672 tons valued at £305,631.

GEMS.—A description of the mineral exhibit of New South Wales would be incomplete without mentioning the display of opal and magnificent gems, for which the State is famed. These include opals, cut and in the rough, from White Cliffs and Lightning Ridge; sapphires, cut and in the rough; beryl, topaz, amethyst, turquoise, zircon, garnet, diamonds from Copeton, and pearls from the northern and western coasts. A skilled lapidary is at work in the building preparing gems for the market.

CONCENTRATES

Readers of the MINING AND SCIENTIFIC PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

TIN PRODUCTION of the Banca mines in 1914 amounted to 15,319 tons, according to consular reports.

STAMP-DUTY at the Tonopah Belmont mill during the year ended February 28, 1915, averaged 8.88 tons per 24 hours.

TAILING from the flotation plant at Anaconda is to be used for making brick. Samples have been tested and found superior to the ordinary pressed brick.

RESTORATION of dredging ground to agricultural use has been attempted successfully not only in California but in Victoria, Australia. To effect this purpose it is necessary to prevent the liquid loam from being lost.

ANOTHER USE for tin has been suggested, namely, to discard the paper bags in which coffee is sold, substituting tin-plate and tin-foil, so that the aromatic oils of the coffee may not be lost during warm humid weather.

A STEEL TUBE-MILL LINER at the Belmont mill, Tonopah, is giving good results. In 16 months one set ground 35,825 tons of ore. It was considered useful for another four months. The lining charge is reduced from 3.2c. for silex to 1.58c. per ton.

TRIBOLUMINESCENCE is the name given to the property of some specimens of zinc sulphide of emitting sparks when scratched. Not only the mineral zinc-blende but the artificial sulphide exhibits this phenomenon. The sparks do not set light to inflammable gases.

CHARACTERISTICS of the region around Hedley, British Columbia, are the deep glacial eroded valleys cutting the plateau over 5000 ft. deep, the intense metamorphism, and indications of a long period of great volcanic activity in the immediate vicinity of the Nickel Plate mine.

COSTS at the North Star mine, Grass Valley, California, were as follows in 1914: mining, $3.043; milling, 62.1c.; cyaniding, 41.5c.; bullion expenses, 3c.; miscellaneous, 29.9c.; New York office, 19c.; taxes, 25c.; and accident and benefit, 9.3c.; a total of $4.941 per ton milled. Sundry revenue reduced this to $4.922.

REPORTS from Peking at the end of January state that the first drill of the Standard Oil Company, at Yen-chang, in Shensi, had only reached a depth of 740 ft., trouble having been experienced with the rig. A second rig has been set up on the Tan-yang-shui, thirty miles south, and has begun drilling.

OPAL MINING at Lightning Ridge in New South Wales is a peculiarly speculative industry. It is said by the Department of Mines of that state that one miner earned $3.60 in 12 months, another $3 in 20 months, but at the end of that time the latter made up all his losses in a few minutes by discovering rich opal. The opal is found in thin veins or as nodules. The matrix is mainly clay occurring in horizontal layers, differentiated from sandstone.

THE METHOD OF MINING to be used at the Inspiration mine, Arizona, will consist of undercutting, thus caving the ore in blocks of probably 70 ft. vertical dimension. The broken and caved ore will be drawn off through a system of inclined rises delivering to the haulage-ways below. These rises have a sufficient number of branches immediately below the caved area to reduce the interval to a minimum, probably 8 ft., between the heads of the rises that reach the caved ore. The mill is designed to treat 14,000 tons of copper ore daily.

DISCUSSING the legal aspect of the smelter-smoke problem, Charles H. Fulton, of the U. S. Bureau of Mines, says that although it has been in the courts for a long time in a minor way, it has been prominent only in the past ten years. During that time, however, and at present it is attracting nation-wide attention. The cases that have been before the courts may be classified geographically under five heads, as follows: (1) Utah, centring about Salt Lake; (2) southeastern Tennessee, near the Georgia and North Carolina boundary line; (3) Montana, centring about Butte and Anaconda; (4) Shasta county, California; (5) near San Francisco,

in Contra Costa and Solano counties, California. There are cases of minor importance in other parts of the country, but those in the five localities mentioned serve well to illustrate the legal aspects of the smelter-smoke problem.

THE TERM 'CRACKING' OF OIL originated about 50 years ago by the stillmen in the old Pennsylvania refineries, and meant just what its connotation conveys, namely, a part alteration, as distinguished from the more complete decomposition which would disrupt the molecule largely into carbon and permanent gas, according to W. A. Hall in a paper read before the Institution of Petroleum Technologists in England. Cracking simply alters the molecules to an extent that produces an amount of low-boiling fractions that cannot be obtained by simple distillation. It may or may not be accompanied by any considerable production of permanent gas, the product being largely a liquid condensate, but of different character from that obtained by simple distillation.

HOGANAS IRON SPONGE, mentioned in the *Press* of April 3 as one of the exhibits of ores and metals in the Sweden building at the Panama-Pacific Exposition, is a pure iron obtained from Swedish ores of the best quality. It is produced by a reduction process, in which carbonaceous gases are used at a temperature below the melting point of iron. The gangue which is present in the ore is retained in the iron, but as nearly chemically pure magnetite is used in the manufacture, the percentage of iron in the sponge is high, even higher than in the purest pig iron. An analysis of the sponge regularly sold is as follows: iron, 96%; sulphur, 0.01 to 0.02%; phosphorus, 0.013%; gangue (principally silica), 2%; oxygen, 0.9%; carbon, 0.03%; and manganese, traces. The sponge is made in the form of round briquettes, about $10\frac{1}{2}$ in. diameter and 2 to $2\frac{1}{2}$ in. thick. The material is somewhat porous, its weight being only about 2 kg. (4.04 lb.) per litre of volume, consequently it has a great tendency to absorb water, making it necessary to cover it during transit. On account of its high quality the sponge is a good raw material for the manufacture of iron and steel of the best grades.

TELEPHONE line construction and operation meets with serious difficulties in the tropics. The main troubles are due, not to the heat, but to the damp and the many natural effects caused by damp heat. The humidity of the atmosphere in many places varies between 80 and 90%. This damp heat produces a marvelous growth of vegetation, so thick that along the sides of the country roads there are actual walls of green leaves perhaps 80 or 100 ft. high, the growth of which is so rapid that they may be cut back one day and grow as high again in the ensuing 24 hours, according to W. L. Price in a paper read before the Institution of Electrical Engineers in England. Insect life is as prolific as the vegetation. White ants are destructive, and other insects make their homes in the petticoats of insulators. Lightning has a virulence unknown in many countries. Wild animals do their best to increase the engineers' labors. In some parts, for instance, it is not unusual to have a mile or two of lines wrecked by giraffes, elephants, or monkeys. When the giraffes roaming over the wilds of East Africa come up against a telegraph or telephone line they have not the sense to draw back or duck their heads, but push on, carrying wires and sometimes poles with them.

THE BUREAU OF SCIENCE has sent a party from the Division of Mines to Surigao province, Mindanao, for the purpose of a geological survey of the iron ore deposits in that province. The party consists of the chief of the division, one mining engineer, and an assistant, who left Manila on February 7. The area and average depth of the iron ore deposit, a blanket of clayey limonite, will be determined, and a sufficient number of representative samples will be obtained to indicate the average quality of the ore. For the latter purpose two prospecting drills are included in the equipment of the party. It will be recalled that the first report of H. F. Cameron, the engineer who discovered the Surigao iron ore deposit, indicated an immense body of ore comparable in quantity with some of the world's largest iron ore deposits. Notes on this ore were published in the *Press* of October 10, 1914. In addition to the survey of the iron ore deposits, a general reconnaissance of northern Surigao will be undertaken, and, if possible, a brief inspection of the recently discovered gold deposits near Iligan will be made. It is estimated that the party will be in the field two months.

THE FINAL FLOW-SHEET at the new 14,000-ton capacity mill of the Inspiration mine, Arizona, has been a matter of considerable discussion. According to the report of C. E. Mills for 1914, the following has been decided on: The test-mill treated 172,722 tons of 1.52% ore last year. This showed that the concentrate will probably contain from 28 to 32% copper and sufficient sulphur for matte in smelting. Many machines and processes have been tried, resulting in the following scheme of treatment for the new mill: Crushing ore to 4-in. size in gyratory crushers, and $1\frac{1}{2}$ in. in Symons disc-crushers, at the mine; reducing this product at the mill, in Marcy ball-mills, to pass a 48-mesh screen; treatment of the mill product by flotation; separation of flotation pulp into sand and slime; concentration of sand; flotation of slime; and dewatering concentrate in a filter-plant. The recovery of copper in the ore as a sulphide has averaged 86.7%. During February it increased to 90.3%. The extraction will depend on the quantity of oxide ore mixed with the sulphide. If the oxide ore is 0.16%, out of a total of 1.52% copper, the recovery of total copper contained would be equal to about 80%; but 86.7% may be expected from the mill from the copper in sulphide form. There is a probability that the copper in oxide form will be in future satisfactorily floated.

REVIEW OF MINING

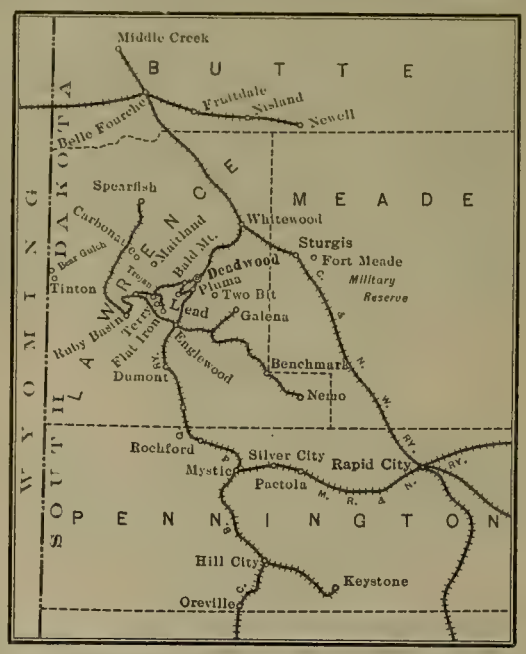
As seen at the world's great mining centres by our own correspondents.

DEADWOOD, SOUTH DAKOTA

BEN HUR MINE AND MILL.—HOMESTAKE NEW MACHINERY.—SINKING AT THE ECHO.

To facilitate handling ore and make a large saving in transport charges, a vertical rise is being driven from the Ben Hur mine, of the Mogul company, to a point near the crusher at the top of the mill. The vertical distance is 485 ft. With the automatic hoist which it is planned to install, ore will be delivered to the mill for a few cents per ton. At present the only means of getting the Ben Hur ore to the mill is to haul it out of the mine through an incline adit over 1000 ft. long, load it into narrow-gauge railroad cars, ship to Englewood, transfer to standard-gauge cars, and then haul up the Spearfish line to the mill. The total distance by rail is 12 miles. Freight costs 65c. per ton. From the point at which the rise has been started, a large tonnage can be taken to it over a grade in favor of the loaded mine-cars. This makes available a quantity of good mill ore, which, by the way, would not yield a profit if handled under present conditions. The rise is being cut 7 by 17 ft., outside of timbers. It will be timbered with square-sets, and divided into three compartments; one about 5 by 5 ft. for hoisting, a smaller one for ladderway, pipes, etc., and a third, still smaller, for a counter-balance. It is proposed to hoist about 5 tons each trip, in a self-dumping skip, using a 2½-ton counter-balance. A 15-hp. motor should handle this load at a speed of about 80 ft. per minute. This would give a capacity of 20 to 25 tons per hour, which is greatly in excess of the mill capacity. Foundations are being prepared in the mill for an 18-ft. tank, to be fitted with a Dorr agitator. It was recently found that the plant could not successfully handle over 120 tons per day with the three 15-ft. agitators at work. The crushing department will easily take care of 150 tons daily. At the present time the bulk of the ore supply for the mill is coming from the North lode, at Trojan, where a 'vertical' in the Cambrian shales, from 6 and 8 to 20 ft. in width, is yielding 75 to 100 tons per day. This property is drawn on to keep the mill fully supplied, after taking care of lessees' ore. At present the Clinton, under lease to William Nicholls, the Mark Twain leased to Thomas Tretheway, and the Alameda leased to Edward Manion, are regular shippers of from 10 to 30 and 40 tons per day. George Salsbury has been granted a lease on the Hardscrabble and will shortly be shipping to the mill. No ore is being taken from the 'Farm,' at the rear of the mill, and it is probable that none will be mined there during the present summer, as other deposits are filling the mill requirements. The Farm is worked by open-cut. Last summer and fall it supplied a large portion of the mill tonnage at a minimum cost for mining. The mill is the first in the Black Hills to adopt the all-sliming method in cyaniding, using Chilean mills and a tube-mill for reducing the ore to a point where only 1 to 2% is coarser than 60 mesh, and 40 to 60% will pass 200 mesh. With continuous decantation using tanks containing Dorr thickeners, and agitating in tanks with Dorr agitators, a satisfactory recovery has been made. The tailing has been discharged from the last thickener without resorting to filtration. Recent experiments with a small filter seem to point to a possibility of saving considerable cyanide and gold-bearing solution by filtering. It is probable that a revolving-drum filter will be installed during the present summer. The executive staff is composed of J. V. N. Dorr, consulting engineer and 'guardian angel'; Charles A. Chase, general manager, who devotes about four days per month to work on the property; E. R. Graham, superintendent, and to whom is entrusted practically all of the details of operation; and L. D. Dougan, mill superintendent.

Construction work at the Homestake is proceeding at a good rate. With the frame of the new hoisting engine at the B. & M. shaft in place, the mechanics are engaged in erection and assembling of the large machine. The steel work of the new head-frame is practically complete. The plant will be ready for operation by the time steam is ready in the new central steam-plant. It is expected that the boiler-plant will be completed by early fall. After its completion the boilers at the B. & M. shaft will be removed. On ground they now occupy will be erected a new air-compressor, one



BLACK HILLS MINING DISTRICT OF SOUTH DAKOTA.

of the largest in the United States, a fitting companion to the hoist, which is stated to be the largest machine of its type ever constructed. It is a vertical type, double-expansion steam cylinders, with the two high-pressure cylinders, in front, direct connected to a shaft to which one of the reels will be attached. The low-pressure cylinders will in similar manner operate a second reel. The engine is rated to handle an unbalanced load of 6 tons from a depth of 4000 ft., at a speed of 85 ft. per second. Two skips will be operated in balance. The skips will dump at the surface direct to two No. 8-K Allis-Chalmers Gates crushers. Belt-conveyors will carry the crushed product to No. 6 crushers. It will drop from them to bins and follow the present practice, namely, transportation to the mills in 4-ton cars drawn by compressed-air locomotives. The addition of the larger-sized crushers

will make it possible to take coarser ore out of the mine, and deliver it to the mills finer than under the present arrangements. At the electric-generating station the building is practically ready to receive the equipment. The building is completed and traveling crane installed. This plant will contain two units of Westinghouse steam-turbines, direct connected to generators. Its maximum capacity will be 4000 kva. The central steam-plant, which will supply steam for the B. & M. hoist and the electric plant, is being erected on a site below the C. & N. W. railroad tracks. The plant will contain six 600-hp. Edgemoor water-tube boilers, three on each side of and facing a steel coal-bunker on top of which the railroad cars loaded with coal will be delivered. Two high stacks will be erected, one for each set of three boilers. The coal-bunker construction is practically complete, and the brick walls of the building are rising rapidly. Foundations for the stacks are finished several feet above the ground-line. At Hanna, where a large portion of the Homestake water-supply is secured, motor-driven pumps are being put in to lift the water over the 380-ft. divide from where it flows down to Lead by gravity. Janesville 3-stage centrifugal pumps, with a total of 550 hp. of motors, are being installed. With the electrification of this plant, and the Deadwood slime-plant, practically all of the Homestake's surface machinery, except the large hoists and air-compressors, will be driven by electricity. Motors are used to drive the stamp-mills, cyanide-plants, machine-shop, carpenter-shop, rock-crushers, regrinding-plant, and for the main mine-pumping system at the B. & M. shaft, as well as for numerous incidental uses.

Shaft-sinking is proceeding at a fair rate at the Echo shaft at Maitland. Since about April 1 some harder rock has been encountered, and it has been possible to drive only about one foot per day, with two shifts of miners employed. In March the shaft was deepened 57 ft. with the same crew of miners. On the 10th, some softer rock was found in one end of the shaft, and if it does not again dip out, an average of considerably better than one foot per day should be made. On the 14th the shaft was 120 ft. deep and in highly mineralized formation. It is proposed to sink to 200 or 300 feet.

LUNING, NEVADA

Renewed Development Work at the Shipper, Luning, Luning Idaho, Mayflower, and Copper Queen Properties.

Since the improved conditions in the copper market there is considerable interest being taken in the properties around Luning.——Joseph L. Giroux has started men working on his company's property. They are down about 800 ft., and propose sinking to water-level before doing much lateral work. It is understood they have a fine body of ore at the present depth.——The Shipper Copper Co. has just had a shareholders' meeting, and proposes starting development at an early date.——The Luning Gold Mine Co. is working away steadily sinking a shaft about the centre of the claims between the principal workings. Timbering the shaft has just been completed, and Mr. Rowland purposes to sink to the contact. Indications are favorable for cutting ore at an early date.——The Luning Idaho Copper Co. has been doing little since the first of the year, but arrangements are now pending for the development of this property on a much larger scale than heretofore.——It is reported on good authority that the Mason Valley Mines Co. has taken a lease and bond on the Mayflower, in New York cañon. This mine is in condition for large production, and it is purposed to extract ore as soon as the smelter at Thompson starts, which will be at an early date.——Fermina's property, known as Copper Queen, it is said will be operated soon under the direction of J. H. Miller, administrator for the estate.——There is much better feeling in camp than there has been since the War broke out, and much activity is expected in the near future.

TORONTO, ONTARIO

Molybdenite and Tungsten.—New Silver District.—Nickel Again.

The Imperial Institute of London has been making inquiries of the Ontario Department of Mines as to the possibility of obtaining a supply of molybdenite from this province. This mineral is much in demand for steel-hardening purposes for armament manufacture at present. Although molybdenite deposits occur in eastern and northern Ontario, so far they have not been worked to any extent. The Institute states that there is also a demand for tungsten for the same purpose. The Department of Mines is making an investigation.

Reports concerning the discovery of a new silver district near Fond du Lac, at the northeast corner of Lake Athabasca in Saskatchewan, about 800 miles northeast of Edmonton, have aroused considerable interest in mining circles here. Glowing accounts of the richness of the area, the conditions of which are stated to resemble those of Cobalt, have been brought in by prospectors. Many people have gone there from Edmonton and Calgary. J. A. Reid, mining engineer of Toronto, has gone to make investigations in the interest of a syndicate of Toronto and Cobalt capitalists.

The nickel question came up again in the Canadian Parliament on April 3, when inquiries were made of Sir George E. Foster, minister of trade and commerce, as to what action the Government proposed to take with reference to the refining of nickel in Canada. Sir George's reply gave little encouragement to any expectations the promoters of the scheme might have formed of assistance from the Government. He said that the Government had arrived at no conclusion, either to prohibit the export of matte or to starting nickel refining. Also that many questions would have to be considered. Capital and equipment would be necessary. The matter may now be regarded as shelved indefinitely so far as the Canadian government is concerned. The Ontario administration appears in no hurry to appoint the promised commission of investigation.

LORDSBURG, NEW MEXICO

Railroad Affairs.—Notes from Various Districts.—Oil Development.—Mogollon Bullion, Roads, and Tailing.

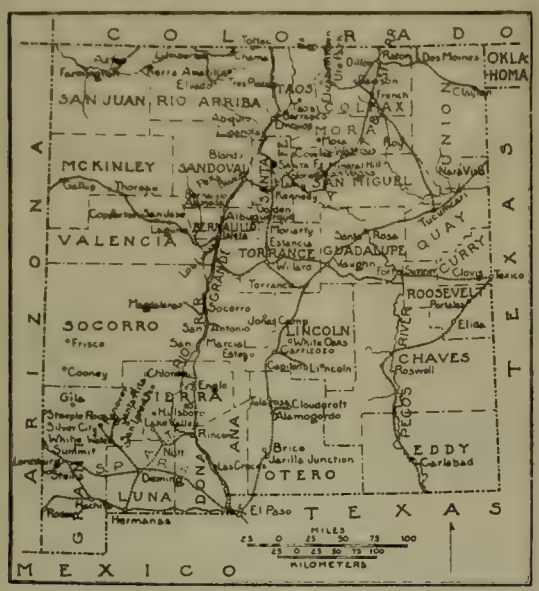
The St. Louis & Rocky Mountain railway has been sold to the Atchison, Topeka & Santa Fe system. This transaction is of importance to the mining regions of northern New Mexico, as the line will doubtless be extended later on by the Santa Fe and afford transportation for some of the now practically isolated mining camps of merit. The road runs from Des Moines to Cimarron, a branch connecting Raton from a point where it crosses the Red river and the Santa Fe. The Arizona and New Mexico railroad and the Southern Pacific system have held a hearing in Santa Fe, before the State Land Commissioner, in connection with the right-of-way dispute between the two roads for the construction of a spur to the 85 mine from Lordsburg.

In the Lordsburg district work continues up to full capacity. Several new companies may start operations.——The Last Chance mine and the Sutton Consolidated Mining Co., at Pyramid, have been absorbed by the El Centro Mining Co., of Los Angeles, California, and probably will soon resume operations.——Several companies are considering the purchase of the Atwood mine. This was recently examined by John M. Sully, manager of the Chino Copper Co., and others. Its favorable location in the Virginia district is bringing the Atwood into prominence.——Shipments at Steins are being made periodically by the November Mining Co.——Several other prospects in the district are showing good ore.

Drilling for oil in the Puertecito field, 28 miles north of Magdalena, will begin soon. A 3000-ft. capacity well-drilling

outfit has been shipped from El Paso, Texas. The Pearson interests are said to be interested in the new concern known as the Magdalena Exploration Co. Over 2000 acres of oil-lands have been leased by the company. J. R. Stancliff, at Lake Arthur, in the Pecos Valley oilfield, has purchased casing and an outfit for drilling west of that place.

The Mobile Mining & Milling Co., of Bayard, New Mexico, is a new corporation which was granted a charter by the State Corporation Commission recently. Mobile, Alabama, people are interested in the company, which is capitalized at $3000. They are developing a good property and are erecting a mill near Bayard. Gold and silver bullion worth $70,000 was shipped in one lot from Mogollon on March 27. There were 48 bars, weighing 3500 lb., in the consignment. It was one of the largest shipments ever made from the district. The post-office at Cooney, in the Mogollons, has been discontinued, and mail for that point will go to Mogollon. The road-building fund being subscribed by the companies of Mogollon and the merchants of Silver City is increasing.



NEW MEXICO.

With the bill passed at the last session of the State Legislature making the road a state highway, it appears that the gold and silver district will yet have a good road for the transport of supplies, bullion, and concentrate. The Silver City fund is practically all subscribed, so that work may be commenced in a short time. The Mogollon milling companies have been warned by the attorney-general of Arizona that tailing must not be discharged into the Frisco river, thereby damaging the lands and streams of irrigation in the Gila valley. The nuisance must be abated or Arizona will take action toward stopping it.——The suit of Paul Davis *v.* the heirs of G. E. Wood, and B. L. Farrar, Martin Fishback, and E. C. Rice for the title of the Excelsior mine in the Organ district of Dona Ana county resulted in a verdict for the defendants. Davis jumped the Excelsior mine, claiming the annual assessment had not been done according to legal requirements. The property is one of the most valuable in the district. With the end of the litigation it is stated that new equipment will be installed at the mine, and operations resumed.——The Yellow Jacket mine at White Oaks, Lincoln county, is again shipping ore to the Pueblo, Colorado, smelter. An adit is being driven. The stamp-mill at the American mine is undergoing overhaul.——The report of the Chino Copper Co. for 1914 has been issued.

BOSTON

Costs and Future of Utah Copper, Chino, Ray, Alaska Gastineau, and Butte & Superior Mines.

In an interview in Boston, D. C. Jackling gave some interesting information about the companies that are under his management. He said:

"The most gratifying achievement at the properties during the past year was the fact that we were able to cut operations to 50% of normal without any perceptible increase in costs per unit of output.

"At Utah Copper the cost during the second quarter of the year, working full time, was 7½c. per pound of copper. In the fourth quarter, working half time, the cost was 7.7c. At Chino the cost for the second quarter was 7.7c. For the fourth quarter, under some adverse conditions, it had increased only to 8c. At Ray Consolidated during the fourth quarter it was 9.1c., the lowest the mine has ever made. The secret of it all is unit operation. Work is so divided into units of reasonable size as to produce maximum flexibility. The idea at all the properties has been to secure the best talent available. We are willing to pay well for it. This also was a factor. We are making important metallurgical improvements at the Utah mills. This will enable us on the same tonnage of ore to extract from 15 to 20% more copper. The additional recovery will be obtained at a nominal cost.

"At the Alaska Gastineau we have done enough to make it clear that we shall be able to mine and mill ore at a cost 20% lower than originally estimated. Tailing losses are under 25c. per ton. The ore, when obtained from normally distributive points, has been averaging from $1.80 to $2 per ton. Recoveries therefore have been over $1.50. The whole operation, however, is so vast that the figures to date are merely indicative and confirmatory rather than final. The property has worked out remarkably well. Every anticipation is being more than realized.

"At Butte & Superior it was originally estimated that zinc would be produced for 4c. per pound. Last year the cost was 0.5c. less than this. As to the life of the property, there is nothing to indicate that we will not be mining ore at the present rate for many years to come."

HOUGHTON, MICHIGAN

Men Employed.—Drilling for Iron.—Iron Ore Shipments.

Nearly 15,000 men are employed at the mines in this district. This is about 1000 more than before the strike of 1913. More will be engaged shortly. Practically all properties are working full time.

A report comes from Ishpeming that the Cleveland-Cliffs Iron Co. is preparing to start diamond-drilling in North lake, about four miles west of Ishpeming. Piles are now being driven through the ice, which is about 20 in. thick, and everything will be in readiness to start work as soon as the ice disappears. The drill will operate near the centre of the lake in about 15 ft. of water. North lake probably will be drained before many years, as it is known that there is ore underneath.

The Miller mine, at Aurora on the Mesabi range, shipped 20 cars of iron ore to the docks at Two Harbors this week. This was the first shipment of the year. For a number of years the Miller has been the first property on the eastern Mesabi to ship in the spring, and the last to stop in the fall. Other mines are preparing to send out ore. It is thought that there will be considerable ore at the head of the lakes by the end of April.

The Oliver Iron Mining Co. is preparing to employ several hundred men in its mines at Ishpeming and Negaunee. A number have already been taken on, but the majority of them cannot be given work until more stockpile room has been provided at the shafts.

THE MINING SUMMARY

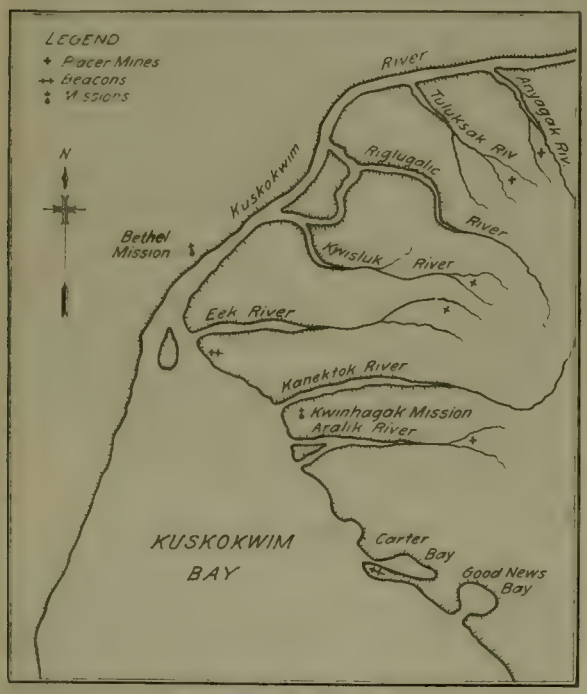
The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

BETHEL

(Special Correspondence.)—People on the Kuskokwim river are greatly indebted to the Seattle Chamber of Commerce for assistance in having the Kuskokwim bay and river surveyed. This will facilitate navigation and connect the states with this unknown region, and will decrease the heavy expenses which exist at the present time.

William McGrogen, an operator from Kwisluk river, is in Bethel making preparation for the next summer's work.—— The reindeer herders are hauling provisions for the new set-



BETHEL DISTRICT, ALASKA.

tlement on Canyon and Fall creek. They will be busy until the river breaks in the spring. Three tons of material has been set up. Men are cutting lumber there. Buildings will be erected to accommodate 35 men or more, as Mr. McGrogen intends to work three shifts.

G. L. Geane is also here from Kwisluk, but is undecided as to his plans for this summer. His ground is deeper and requires machinery. Last summer the ground worked produced a good average and paid well. The gravel was from 5 to 8 ft. deep, and at times 50-cent pans were found 5 ft. from bedrock. Most of the time the 'pay' was on bedrock, which is a porphyry.——There are a number of other prospectors on Kwisluk, Tuluksak, Yagak, and Aralik rivers, busy getting things in shape for next summer's work.——Mr. Gabrielson, on Aralik river, put in a Headley scraper, run by a 12-hp. gasoline motor, last summer, with a capacity of one-third cubic yard. The gravel is 8 ft. deep and yields 25c. per sq. ft. on bedrock. The scraper was operated 15 days and yielded $100 per day. On account of not having sufficient cables, the scraper could not work to full capacity. Mr. Gabrielson has the scraper in first-class order now, and expects to start work in May, when the river breaks. He stated that there is hardly any frost in the ground this year on account of the mild winter.

Bethel, February 6.

FAIRBANKS

On March 29 the Yukon river was open in several places between Tanana and Birches. This year's break-up is earlier than previously.——The Tolovana district has been well prospected, and many people are optimistic. According to P. Lynch, the 'pay' on Olive creek is 200 to 250 ft. wide. Estimates average the gravel at $2.50 per foot. Bedrock is at 24 ft., 10 ft. being 'muck.' Jay Livengood, who discovered gold at Tolovana, has sold his claims to D. Cascaden for about $40,000.

NOME

Rich gravel is reported by telegraph as being found on Dexter divide, four miles from Nome. 'Pay' is estimated as 12 ft. deep, 60 ft. wide, and a good length.

ARIZONA

GILA COUNTY

Copper production from the Inspiration Consolidated Copper Co.'s mine will commence in June of this year, according to the general manager, C. E. Mills, in his report for 1914. It was again decided to increase the size of the mill. It will finally consist of 18 units, each having a capacity of 800 tons per day. By September, 7000 tons per day will be treated and at the end of the year the quantity will be 14,000 tons.

Mine development, in charge of Mr. McDonald, was confined to the Inspiration. No work was done in the Live Oak. Total work accomplished was 102,066 ft., or 19.33 miles. To date the length is 42.9 miles; also 29.33 miles of churn-drilling. At the end of 1914 there was 192,842 tons of 1.65% ore stored on the surface. The New Keystone property was acquired during the year for $795,940. Ore reserves in the company's properties are estimated as follows: sulphide, 46,252,000 tons of 2.01%; low-grade sulphide, 28,698,000 tons of 1.26%; oxide material, 17,460,300 tons of 1.31%; and 4,732,700 tons of 1.31%; making a total of 97,143,000 tons averaging 1.63 per cent.

The balance-sheet at December 31, 1914, showed accounts receivable, $225,219; bond subscription unpaid, $722,865; and cash, $1,691,792. Current liabilities amounted to $288,703.

YAVAPAI COUNTY

The Arizona Power Co., which is the only concern selling power in this county to mines and for domestic purposes, is to spend about $250,000 in enlarging its plant on Fossil creek. The new equipment will include a 2000-hp. generator, nearly four miles of steel flume, 3000 ft. of pipe, a diversion dam, and an intake tunnel 440 ft. long. The United Verde smelter will use more power. A transmission line is being constructed to the De Soto mine. R. S. Mason, the chief engineer of the company, is at Prescott. Preliminary work has been started.

The Buffalo-Arizona Consolidated company's mill, 11 miles from Hot Springs, was destroyed by fire last week. The damage is estimated at $20,000.——The Montezuma company's adit near Crown King is to be extended to about 3000 ft. from the portal. Drilling equipment has been ordered. A fair quantity of ore has been opened. J. P. Waldron is manager.——The Lynx Creek dredge has been moved.

CALIFORNIA

Amador County

The Mountain King and Queen properties at Pine Grove are under option to Russell Robinson for $100,000. He is developing them under a new agreement with the owner, W. B. Pitts.

Butte County

Re-dredging dredge tailing has frequently been discussed in California. According to Charles Helman, manager of the El Oro Dredging Co. at Oroville, tests have shown that a modified boat will save enough gold to make re-dredging profitable.

Calaveras County

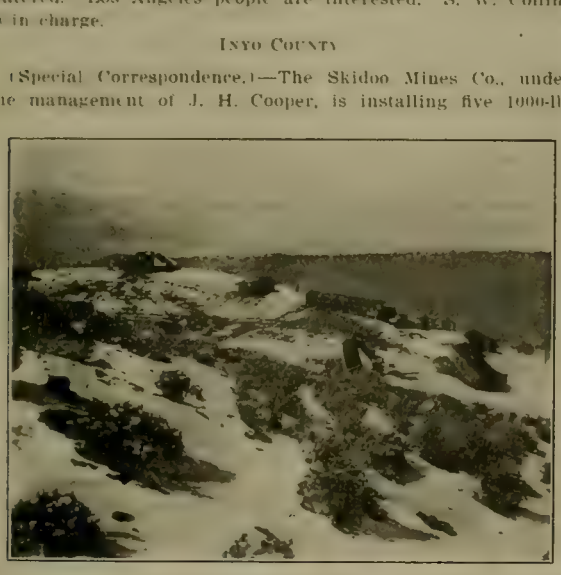
A better feeling prevails at San Andreas regarding the mining situation.——The Ford mine is being unwatered. J. C. Benson controls the property.——The Felloweraft is also to be unwatered.——Preparations are under way to re-open the Pioneer Chief.

Eldorado County

Records with the county recorder at Placerville show that the Golden Rod, Empress, and Minerva, and the property of the Union Gold Mining Co. have changed hands.——The Alpine mine, three miles south of Georgetown, is being unwatered. Los Angeles people are interested. S. W. Collins is in charge.

Inyo County

(Special Correspondence.)—The Skidoo Mines Co., under the management of J. H. Cooper, is installing five 1000-lb.



SKIDOO MINES.

stamps. There are ten working now. Two Deister concentrators are also being installed. The additional plant is expected to be in operation by May 15.——At Harrisburg, the five-stamp mill is working one shift daily, as only a small amount of ore is on hand. Murphy and Trent are installing a cyanide plant to treat the accumulated tailing. Seven men are employed.——The antimony mine at Wild Rose is shipping 12½ tons of oxide ore to the Merchants' Finance Co.'s smelter, near Los Angeles. The sulphide ore is being treated in a six-ton reverberatory furnace, two miles from the mine. The sulphide ore analyzes 40% antimony.

Skidoo, April 15.

Kern County

Three feet of rich gold ore has been opened for 40 ft. on the 170-ft. level of the old Long Tom mine. The company is to sink a shaft to 500 ft. to cut the Lady Langtry vein, which was a good producer. I. M. Hirsfield is in charge of 30 men.

Mariposa County

The report of the Mountain King Mining Co. for the year ended March 31 includes the reports of the president, W. S. Miller; superintendent, A. Hamilton; engineer, R. Van Norden, and secretary, H. T. Harper. The property is in a transition stage. A new mill and power-plant are being constructed. The former was started on February 13. It contains a 350-kva. generator driven by a 450-hp. Francis turbine. Work at the mill is well ahead. Mine development amounted to 1209 ft. Other necessary work was done. After a considerable amount of prospecting, a new vein was cut. It has been opened west for 251 ft., averaging 9 ft. in width. In the centre of the vein is a 12 to 18-in. streak. It contains free gold and sulphides. Two stopes were started, showing the following: length, 189 ft.; average width, 8.7 ft.; and value, $8.80 per ton. There was 1200 tons of ore, worth $4.64 per ton, crushed from the low-grade shoot. In March 900 tons yielded bullion worth $3550 and concentrate valued at $756. Reserves are estimated at 60,000 tons worth $6 per ton. From ore-shoot No. 1, on which stoping was completed early in December, 3374 tons milled averaged $9.60 per ton. The total from this body is 4266 tons for $42,373.

Revenue during the year amounted to $108,197, made up as follows: bullion and concentrate, $47,682; cash at April 1, 1914, $15,281; and loans, etc., $45,234. Expenses were: operating, $47,698; plant, $48,977; engineer's fees, etc., $5688. Cash on April 13, 1915, amounted to $5832.

Nevada County

The North Star Mines Co. has paid its regular quarterly dividend of 20c. per share, equal to $50,000.——At the Empire mine ore is being opened at 4600 ft. It is reported that the apex rights dispute between the Empire and North Star has been settled.——At the Union Hill 10 stamps are crushing ore. The 800-ft. level is being extended to cut the Union Hill vein.——Four miles below Grass Valley is Deadman's Flat. Considerable activity is apparent there at present.——At a depth of 360 ft., a drift on the Forlorn Hope vein of the Black Bear mine, in the Rough and Ready district, is showing 3 ft. of rich ore. The 10-stamp mill is to start soon. Fifteen men are employed in charge of William Buchholz.

Placer County

It is reported that the old Whisky Diggings mine, northeast of Lincoln, will be re-opened by Wallace Gibson. The ore contains gold and copper.——The Herman company, at Westville, may install an electric plant this spring. Four veins are to be developed.——Work has been resumed at the Rip Van Winkle and Green Immigrant mines.

Shasta County

The boat of the Shasta Dredging Co. is to be moved from Horsetown to another area 12 miles distant. The dredge will be dismantled for removal. A. G. Frost, of Redding, has the contract for $6000.——On April 20, W. Hooper, shift boss at the Gladstone mine, was killed. A barrel fell down the shaft 700 ft., broke the bonnet of the cage, and then hit him.——The Noble Electric Steel Co. is resuming production of ferro-manganese and ferro-chrome. The Northern California Power Co. will supply the electricity, amounting to about 2400 horse-power.——The Midas mill and cyanide plant yielded $6000 in the past two weeks.——Eastern people have bonded 1277 acres of dredging ground on Churn creek.

Tuolumne County

At 2700 ft. in from the portal, good ore is showing in the adit of the Experimental mine at Columbia.——The Springfield Tunnel & Development Co. has cut the old Buchanan channel by a 225-ft. rise from the 2400-ft. adit.

COLORADO

Clear Creek County

The remodeled mill at Idaho Springs is receiving a good supply of ore. Concentrate shipments have been started.——

The shoot recently opened in the Waldorf mine in east Argentine is producing rich ore. The last shipment of 22 tons averaged 1.53 oz. gold, 67.1 oz. silver, 8.05% lead, and 12.85% copper. The average value was $91.94 per ton.——Lessees and others in the district continue to be busy.

LAKE COUNTY (LEADVILLE)

Six furnaces are in blast at the Arkansas Valley smelter. The yards are full of ore.——Pumps at the Penrose shaft are ready to start. Great interest is now centred on this drainage scheme.——Three shifts at the zinc-oxide plant are treating 48 tons of zinc carbonate ore per day.——The spelter market has affected some of the zinc-ore producers. No settlements have been made for ore shipped a month ago.——Lessees at the London mine are extracting high-grade gold ore. Shipments have been delayed on account of the railroad being blocked with snow. Haulage is expensive from this property.——A shoot of rich lead ore is being mined at the Hope shaft. The daily output of the mine is about 25 tons. A large body of ore containing 12% silica, 26.3% iron, and 26.5% manganese was opened some time ago. Arrangements are being made with the Illinois Steel Works of Chicago to supply some of this ore.——The Garbutt mine is producing 50 tons of $16 to $20 ore per day.——A mill to cost about $50,000 is contemplated for the Gordon-Tiger. G. W. Boyce is manager.

LA PLATA COUNTY

A rich vein, 2½ in. wide, has been opened in the Incas mine near Durango.

OURAY COUNTY

Ore being treated at the Atlas mill contains gold, silver, lead, and copper. Water concentration formerly saved only about 65%, but the Minerals Separation flotation process has increased this to 90%. The manager, Mr. Carroll, expects to extract 95% before long.——Two miners were killed in the Wanakah mine last week. Their machine drilled into a missed hole.

TELLER COUNTY (CRIPPLE CREEK)

The Vindicator Consolidated Gold Mining Co. attracted considerable attention recently when it acquired control of the Golden Cycle properties in Cripple Creek. The reports of the president, Adolph J. Zang; vice-president and general manager, Irving T. Snyder; superintendent, H. P. Nagel, Jr.; mine engineer, Fred W. Crosley; and secretary and treasurer, G. S. Wood, contain the following information for the year 1914: Development totaled 6105 ft., making 198,208 ft. to date. No. 1 shaft was sunk from 1626 ft. to 1943 ft. Stations were cut on No. 22 and 23 levels, 183 and 308 ft. below No. 20, or 1600-ft. level. During December a large flow of water was cut on the 1800-ft. level. Pumps were installed to lift it to 1600 ft., from where it will flow into the Golden Cycle mine. Operations underground were curtailed on account of improvements being made. Reserves of broken ore were heavily drawn on. Development on company account was mostly done on the lower levels. The orebodies at 1600 ft. show a large tonnage. From No. 1 shaft the company produced 76,295 tons of ore. This yielded 26,343 tons of $27.04 ore for shipment. Lessees produced 3897 tons of $33.58 and 9741 tons of $19.79 ore from No. 1 and other shafts respectively. The lower levels of the mine were wired for electric lighting. A 25-drill Sullivan motor-driven compressor of 1900 cu. ft. capacity has been installed. The gross revenue from all ore shipped was $802,280. Operating expenses totaled $335,708, and $165,712 was paid to lessees. This left an operating profit of $300,860. Adding sundry income, and deducting other expenses, the final profit was $251,157. Cash on hand at the beginning of the year was $227,112. Dividends amounted to $270,000. On January 1, 1915, the cash balance was $208,270. The new concentrating mill started on October 15. Its purpose is to treat ore-house waste and material that has been put on waste-dumps.

IDAHO

SHOSHONE COUNTY (COEUR D'ALENE)

The orebody that was faulted in the Caledonia mine several weeks ago has been found. The general manager, Charles McKinnis, states that the occurrence is similar to that in other parts of the property.——In the lower adit of the Silver Cable, east of Mullan, a rise has entered ore assaying up to 60% zinc, with some gold and silver. This is under the great shoot in No. 2 adit.——Construction has been started on the 100-ton mill at the H. E. & M. mine. R. Hunter is in charge.

MISSOURI-KANSAS-OKLAHOMA

In the first 16 weeks of 1915 this region has produced the following: blende, 74,898 tons; calamine, 5973 tons; and lead, 12,067 tons. The total value is $4,202,098. According to the *Joplin News Herald*, the following are the chief features of the district: New mill construction is a feature of much importance at this time. Work will start within a week on a 1000-ton concentrating plant for the Granby Mining & Smelting Co., 1½ miles south of Granby, Missouri. O. W. Sparks, operator of several large mines, announces that within 20 days he will commence building two 300-ton mills. Both of these will be situated in the west Joplin sheet-ground district. The rejuvenation of several large properties, likewise, is attracting attention. In the Lincolnville, Oklahoma, district, where no mining of importance has been conducted for three years, the Underwriters Land Co. is draining the drifts of the Mission and the Omaha-Petersburg mines. Both these properties are equipped with large mills. North of Miami, Oklahoma, the Picher Lead Co. has four shafts down to a depth of 95 ft. A fifth is down 20 ft. This work is in a virgin district, several miles removed from the nearest mines. Extensive drill prospecting has shown an enrichment of importance at this point. The Picher company plans to construct two 1000-ton mills on this property.

MONTANA

BROADWATER COUNTY

The Townsend district is fairly active at present.——The Broadwater County Mining Co. has decided to have its property reported on and developed.——Lessees and miners at the Black Friday, East Pacific, and other mines are busy.

JEFFERSON COUNTY

Twenty-one miles east of Butte is the Pipestone district. It is showing increased activity. Good copper ore was recently opened in the Smuggler claim. At 75 ft. in the Gold Bug there is 3 ft. of 5½% ore. At 110 ft. in the Welcome Stranger is 3 to 4 ft. of fair ore.

SILVERBOW COUNTY

The U. S. Bureau of Mines rescue-car No. 5 has gone to the Washoe smelter at Anaconda. From February 16 to April 17 it was at the Butte mines, in charge of J. L. Boardman. A large number of men received instruction in first-aid. The Anaconda company facilitated the work in many ways. The car remained at Anaconda until May 1. It then went to the coal mines of the state. A first-aid contest will probably be held in Butte before long.

At the Butte & Great Falls mine, northeast of Butte, the shaft is down 350 ft. It will be sunk another 150 ft. The country is granite.——It is probable that the Butte & London will be re-opened.——The Anaconda company is preparing to resume work at the Lexington mine in the Walkerville district. The shaft is 1450 ft. deep. About 400,000 tons of zinc ore has been blocked out.——Rich ore has been opened at 2800 ft. in the West Stewart mine of the Anaconda.——The annual report of the Butte & Superior states that 327,210 tons of ore was treated last year. The net profit was $1,417,128. Ore reserves are estimated at 1,030,000 tons, averaging 20% zinc and 7 oz. silver per ton. On the 1500-ft. level east of the Black Rock claim the Mammoth zinc lode was cut last week. It is 60 ft.

wide at that point. In the west 1300-ft. level a good deal of copper is contained in the zinc ore.

In 1914 the mine of the East Butte Copper Mining Co. only worked 229 days, being idle from August 8 to December 31. While in operation, the yield was greater than the rate in the previous year. Development in the Pittsmont totaled 4814 ft. The main shaft was sunk from 1585 to 1770 ft. Development in the upper levels opened a large tonnage of new ore. Other parts of the property showed good results. Improvements at the mine and smelter were completed and started. Operations were as follows:

	1914.	1913.
Ore treated, tons	110,992	186,815
Copper yield, pounds	9,175,579	14,401,108
Silver, ounces	242,347	506,897
Gold, ounces	2,219	8,803
Value of metals sold	$1,291,676	$2,471,551
Other income	163,779	174,017
Expenses	1,048,856	1,881,112
Surplus after paying other items	222,252	531,772

NEVADA

Churchill County

On May 21 the Nevada Wonder company will pay a dividend of 5c. per share. This amounts to $70,415. Total is $563,120.

Clark County

In the Los Angeles Chamber of Mines and Oil monthly organ, *Oil and Mining Bulletin*, J. Nelson Nevius contributes a paper entitled 'Reconnaissances of the Goodsprings Mining District.' It is accompanied by illustrations and a map; while all of the important properties are described, including the Boss mine, in which platinum-bearing ore was found in 1914. Mr. Nevius concludes his paper as follows: "This region gives every promise of becoming an important and steady producer of lead and zinc ores of high grade. Virgin outcrops can be seen in the 'ore lime' horizon throughout the district, and as practically none of the zinc mines has opened orebodies too small to be profitable intelligent development should open many new mines of importance. Several of the present properties would bear exhaustive examination with a view to developing them on a large scale. The pronounced financial success of the Yellow Pine indicates the possibilities of these mines when financed and capably managed, and the investment of new money in this mine was small. The discovery of rare metals in the Boss mine is new to mining, and only proves that there are lots of things which we do not know yet. It is an important discovery and a valuable property, but how big or how important, or how the ore will be treated, or how much it will cost, is not yet known by anyone. It has been proved that platinum is not confined to this mine alone, and other discoveries may be expected, especially after the geology of the Boss is better understood. There is no occasion for excitement, or the paying of fancy prices for the privilege of developing the other fellow's prospect; but the district offers an excellent opportunity for intelligent investment of mining capital after thorough examination of all conditions."

Esmeralda County

If certain arrangements are made, and it can double its business, the Goldfield Consolidated Water Co., will reduce its rates by 50%, according to C. G. Patrick, manager of the company.——Litigation is discussed editorially in this issue of the *Press*.——The rise from 1750 ft., and winze from 1400 ft. in the Atlanta have connected. Better ventilation has resulted. Ore extraction will be increased.——The Goldfield Consolidated Mines Co.'s final report for March contains the following: ore treated, 32,049 tons; net profit, $170,965; total cost, $5.43 per ton; development, 3526 ft.; cost per foot, $5.97; lessees production, 1215 tons valued at $40,678.

Officials of the Jumbo Extension and Merger companies failed to agree as to terms in the apex suit on April 28. They have left San Francisco for Nevada.

Nye County (Tonopah)

The Tonopah district produced 10,109 tons of ore valued at $207,922 in the week ended April 24.——Extension profits were $55,838 in March.——The Belmont shipped 118,242 oz. of silver last week.——The West End forwarded 16,978 ounces.

According to the general manager, J. L. Josephs, the property of the MacNamara Mining & Milling Co. was operated for eight months in 1914. The shut-down was due to lack of development, shortage of money, and the low price of silver. The mine and plant are in good condition. The general superintendent, J. W. Sherwin, reported that development down to 800 ft. amounted to 2018 ft. The mill treated 15,776 tons of ore averaging $11.08 per ton, with 93.3% recovery. Custom ore totaled 5232 tons, and the company's output of 10,544 tons assayed $7.04 per ton. The average price received for silver was 55.6c. per ounce. Costs for seven months amounted to $10.344 per ton.

Including assessments, $43,477, the revenue totaled $219,396. The cash balance was $1277 at the end of 1914.

OREGON

Baker County

The Powder River Dredging Co. is constructing a 9-cu. ft. boat near Sumpter. The one already at work is of 7-ft. capacity.——At Gold Center, J. B. Wetherell and partners have ordered a dredge from the Union Iron Works at San Francisco.

Josephine County

(Special Correspondence.)—The copper claims of the United Copper & Gold Mining Co. were sold last week to Charles O. Wheeler & Co. of Scranton, Pennsylvania, for $250,000, on terms. They are situated 33 miles from Grant's Pass.——Extensive development is to be started by the new owners. It is almost certain that the railroad from Grant's Pass to Crescent City, California, will be completed. Twohy Bros. have taken over the partly constructed line, and state that they will finish it. Engineers are now investigating the work done, and to be constructed.——The old Concord coach and horse-teams for freight have been taken off certain roads in the western part of the county. Automobiles and trucks are carrying everything.——Kerby, Waldo, Holland, and other western mining towns and districts are waking up, and more mining is being done in that area than for many years.

Grants Pass, April 15.

TEXAS

(Special Correspondence.)—According to William B. Phillips, director of the bureau of economic geology and technology at the University of Texas, drilling at 875 to 1700 ft. in Potter and Randall counties has disclosed a larger quantity of potash than has been found in any wells in the United States. The two wells are 35 miles apart, 23 miles northwest and 16 miles southwest from Amarillo, respectively.

Austin, April 10.

UTAH

Juab County

It is stated at Eureka that Utah smelters are negotiating for the silicious ore and tailing dumps at the Eureka Hill mine.

Salt Lake County

The report of Frederick Cowans, manager of the Utah Consolidated Mining Co., for 1914 shows the following: ore reserves are estimated at 256,321 tons of copper ore averaging 1.90% copper, 0.54 oz. gold, and 0.697 oz. silver; and 50,365 tons of lead ore averaging 16.48% lead, 0.48 oz. gold, 2.68 oz. silver, and 0.60% copper. There was mined 153,345 tons of copper ore and 48,482 tons of lead ore, which yielded 7,584,391 lb. copper, 14,588,276 lb. lead, 284,196 oz. silver, and 15,528 oz. gold. The profit was $565,666, against $636,470 in 1913. Div-

idends totaled $600,000, compared with $450,000. The year started with a surplus of $772,096, and ended with $632,175. Copper on hand is valued at $749,319.

According to Lee Glockner, who recently visited the south fork of Big Cottonwood cañon, where are the Kennebeck, Carbonate, Tar Baby, Rexall, Reed's Peak, Big Cottonwood Consolidated, Cardiff, and others, the last named has about 90,000 tons of silver-lead ore opened. This will average $25 per ton. When the roads are better, shipments will be resumed to the smelters.

SUMMIT COUNTY

Ore shipments from Park City during the first quarter of 915 totaled 26,375 tons. This is an increase of 7430 tons over the quantity in that period of 1914.——At the 2300 ft. the Daly-West company has started to drive to the Daly Judge mine. This will open new ground in the latter.——Further trouble has arisen with the Silver King Consolidated. W. D. Foster alleges that Solon Spiro, the president, planned to rob the company of $303,746.09. The plaintiff wants an accounting of this money.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—Back pay, amounting to 30% of what was owed them, has been paid to the men who were employed by the Western Union Mines Co.——At the Knob Hill 15 men are employed. The weekly output is 100 tons. Most of this comes from 300-ft. depth, north of a trachyte dike.

Republic, April 24.

After being held by a receiver for two years, the property of the North Washington Power & Reduction Co., of Republic, consisting of concentrating mill, power-plant, and other equipment, has passed into the hands of Spokane men. It will be re-started. The property has been purchased from W. W. Tolman, receiver, by F. R. Clark, a Spokane mining engineer, for $25,000. Adjoining holdings also have been secured by Mr. Clark, and the entire property organized under the name of the American Reduction Co., having authorized capital of $250,000. The incorporators of this new company are F. R. Clark, P. N. Clark, and G. W. Sommer.

STEVENS COUNTY

The northern part of this county, around Colville, promises to be more active this season than before. The Bonanza and Dominion mines are working, while the Clugston, Meyers Falls, and others are about to resume.——Increased interest is being taken in the Tuck district.

The Scotia mine, on the east side of Kettle river between Marcus and Orient, will be worked this spring. A 2500-ft. tramway is to be erected connecting the mine with the Great Northern line. The Scotia ore, with high copper content, will be handled by the Granby smelter.——An appropriation of $25,000 has been made for re-opening and timbering the Old Dominion mine on Dominion mountain near Colville. The mine contains a rich silver-lead orebody, and more than $1,000,000 has been extracted in the last 30 years, of which $650,000 has been spent in development. The mine has 17,000 ft. of workings. W. H. Linney, of Spokane, is president of the new organization to handle the project, the Dominion Silver-Lead Mining Co. The other officers, all Spokane men, are R. C. Lammers and A. E. Gallagher.

WYOMING

BIGHORN COUNTY

Near Byron, the Ohio Oil Co. has brought-in a well producing 25,000,000 cu. ft. of gas per day. There are five wells in the district yielding a total of 50,000,000 ft. Two of them belong to the Utah-Wyoming Consolidated Oil Co. This company has a well down 1350 ft., and oil is expected within 400 ft. The Montana & Wyoming Co. is sending oil to the refinery at Cowley. Five wells are being drilled in the district.

CANADA

BRITISH COLUMBIA

Owing to the depression in the metal-markets, the British Columbia Copper Co.'s revenue in 1914 decreased from $1,904,695 to $911,355. Operating expenses were $788,685. Payments for custom ore amounted to $162,435. Development has continued. Normal production will be attained soon.——On March 31 the Hedley Gold Mining Co. paid 5c. per share, equal to $60,000. The total to date is $1,583,520. The annual report of this company includes the following information: All ore treated was extracted from the Nickel Plate mine. Development generally was satisfactory. The Dickson incline shaft was sunk to 750 ft. Stations were cut, and equipment installed. The new water-power plant of 2100-hp. turbines, driving a 1250-kva. generator, was started on January 2, 1915. It cost $192,009, $7991 below the estimate. A motor-driven compressor was also installed. Mine buildings were rearranged. A new jaw-crusher and tube-mill were erected in the mill. Ore production was 78,494 tons averaging $10.80 per ton. Cyaniding and concentration recovered 94.09%, a total of $797,341. The profit was $388,289. Dividends amounted to $300,000. Surplus at the beginning of 1915 was $360,325. G. P. Jones is superintendent of the property.

Ore shipments from Rossland mines in the week ended April 7 were as follows: Centre Star, 3250; Le Roi, 3400; and Josie, 318 tons.

ONTARIO

Rich ore is still being mined at this mining centre. Narrow veins of 2000-oz. ore are not uncommon. In an open-cut of the Townsite City mine of the Mining Corporation of Can-

ada, the specimen shown in the accompanying photograph was found recently. It was only a few feet below the surface. The slab is approximately 10 in. thick and 48 in. square, assaying over 4000 oz. per ton. It weighs 2600 pounds.

Pumping out Kerr lake has been resumed.——Construction of the 100-ton mill at the Schumacher mine has been started. It will consist of a revolving grizzly, Buchanan crusher, Jeffrey belt-conveyor, ore-bin, belt-feeder, Hardinge ball-mill, Dorr classifier, tube-mill, Dorr agitators and thickeners, clarifier, and Merrill filter-press.——The report of La Rose Consolidated Mines Co. for 1914 shows that the output of 1,368,247 oz. silver was a decrease of 1,268,449 oz. The profit was $217,979. Dividends amounted to $749,313. The year started with a surplus of $1,602,005, and ended with $1,040,380. Ore reserves are estimated at 47,464 tons, containing 859,919 oz., a large decrease.——A new paper, *The Northern Miner*, has made its appearance in this province. It is a weekly, published by Ben Hughes at New Liskeard. It contains a résumé of the latest of interest to mining men.

YUKON

On April 9 the Canadian Klondyke company had 400 men preparing its dredges and other plant for the coming season. A new pumping station was being erected above the mouth of Hunker. The manager, Charles Boyle, expected to start three boats soon after. No. 2, which capsized in October, will not be ready for a time.

KOREA

Profit of the Oriental Consolidated in February was $81,488. This was made up as follows: Operating profit, $51,532, less improvements, $26,043, leaving net, $25,489, plus insurance collected on Maibong mill and power-plant, $56,000, making $81,488.

MEXICO

SAN LUIS POTOSI

Resumption of mining operations in San Luis Potosi depends on political and transportation conditions. Mining men are anxious to resume, and have been watching conditions closely, according to U. S. consul Wilbert L. Bonney, at San Luis Potosi, on March 29. The re-opening of mines depends also on the re-starting of operations by the smelters. Difficulties of the smelters are numerous and complicated. The coke supply must come through Tampico. Last fall when conditions for a time were somewhat promising, a moderate supply of coke was received by the smelters. It is still on hand. At the same time a limited amount of cyanide was imported. At that time, September 1914, the representative of a large smelter in the San Luis Potosi district informed his consulate that 20 tons of coke per day could be used if transportation could be furnished for getting it from Tampico. At the same time a leading importer informed the consulate that he would buy 50 tons of cyanide if it could be obtained. Shortly afterward communications with Tampico and with Saltillo were interrupted. Hope of resuming mining was abandoned for the time. The smelters are further embarrassed by the necessity of obtaining a variety of ores from distant regions in order to make a proper mixture for economical treatment. Cyaniding will be resumed earlier than lead smelting, probably soon after transportation becomes regular. A mining and milling company at Guanajuato has continued operations under difficulties. At Cedral, silver and quicksilver have been extracted from tailing. No product has been shipped for months. At Charcas a small amount of ore has been taken out. It cannot be shipped to smelters. Copper mines at Charcas and Matehuala belonging to an American company have been shut down. No date is set for opening. The sulphur mines of an American company near Cerritos have long been closed. An agent of the company who is now in San Luis Potosi gives little hope of early resumption. The mines at San Pedro are merely keeping their work in proper condition for re-starting when the situation becomes favorable. In general, mining men are awaiting the opening of the Tampico route, the return of settled political conditions, the determination of taxes, and better labor conditions. Before they can plan resumption they must be assured that they can export their product safely and profitably, and that they can secure supplies promptly. Mine-owners are most anxious to resume. They have kept in contact with their employees to hold their organizations together. None of those now in San Luis Potosi is willing to set any date for resuming.

The INSTITUTE OF METALS held its annual meeting in London on March 12 and 13. Papers covered copper-aluminum alloys, effect of rapid cooling on the constitution of binary alloys, copper-tin alloys, etching reagents, nickel-aluminum alloys, copper-nickel-aluminum alloys, appliances for metallographic research, micro-chemistry of corrosion, and the effect of heat and work on the mechanical properties of metals.

PERSONAL

ALBERT BURCH is a Goldfield.

H. C. BAYLISS has gone to Siberia.

W. H. ALDRIDGE is in Northern Mexico.

LEWIS A. WRIGHT, of New York, is here.

JAMES W. NEILL is here from Pasadena.

C. M. ROLKER is in New York from London.

W. J. CHALMERS is at the St. Francis Hotel.

GEORGE C. SCHROTER is here from New York.

T. A. RICKARD is visiting Goldfield and Tonopah.

RENSSELAER H. TOLL, of Denver, is at Angels Camp.

F. CHARLES MERRY is spending a holiday in New York.

SCOTT TURNER sails from New York for London on May 1.

C. H. MUNRO is returning from Colombia to New York.

W. J. LORING is at Sonora, in Tuolumne county, California.

J. A. BURGESS, superintendent of the Nevada Wonder mine, is at Berkeley.

FREDERICK B. IRVINE is now with the Morgan Engineering Co., at Dayton, Ohio.

M. S. BRANDT is engineer to the Seneca Consolidated Gold Mines in Plumas county.

C. L. BRUNS, engineer for the Cuba Copper Co., has been spending a holiday in New York.

R. VAN A. NORRIS has been elected president of the Columbia School of Mines Alumni Association.

GELASIO CAETANI has received a commission in the engineering department of the Italian Flying Corps.

R. T. HIRSH has returned to New York from the examination of placer deposits along the Rio Tocatina, in Brazil.

MASAO IKEDA, professor in the Royal Mining Academy of Akita, Japan, has been visiting our Western smelters.

WILLIAM F. JAHN, metallurgical engineer, from San Juancito, Honduras, is sojourning in San Francisco on his way to New York.

F. BURNETT, superintendent of one of the properties of the Oriental Consolidated Mining Co., is in the United States for a holiday.

Information is desired as to the whereabouts of THOMAS C. HOWELL. Please notify L. S. HOWELL, 1720 Pacific avenue, San Francisco, California.

FREDERIC R. WEEKES, for the past five years connected with the New York office of A. CHESTER BEATTY, will continue his engineering practice at 71 Broadway, New York.

Schools and Societies

The INTERNATIONAL ENGINEERING CONGRESS, to be held in San Francisco in September, announces that Vol. III of its transactions will comprise about 20 papers on the general subject of municipal engineering.

The COLORADO SCHOOL OF MINES senior-class tour this year started on April 26. Between that date and May 24 it will include Colorado Springs, Victor, Concrete, Florence, Canon City, Leadville, Breckenridge, Shoshone, Carbondale, Marble, Redstone, Castle Gate, Salt Lake City, Bingham, Magna, Tooele, Garfield, Park City, and Denver.

The STATE SCHOOL OF MINES at Salt Lake City announces that applications will be received up to May 15 for five research fellowships in metallurgy. Each has an annual value of $720. Applicants should send copies of their training to the director, Joseph F. Merrill. Although there has been quite a little bit of trouble between the University and some of the members of the faculty, the Department of Metallurgical Research is not affected as it is entirely under the direction of the Bureau of Mines in co-operation with the State School of Mines.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, April 29.

Antimony	.25	—25¾
Electrolytic copper	.19	—19¼
Pig lead	4.45—	5.45
Quicksilver (flask)		$70.00
Spelter	.15	—15¼
Tin	.45	—46½
Zinc-dust, 100-kg. zinc-lined cases		16

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, April 29.—Copper is strong and advancing; lead is dull, spelter is excited with a runaway market.

COPPER

Prices of electrolytic in New York, in cents per pound.

The present price of copper is due to the great exports used in munitions of war, nothing else. Best grades of Lake copper have been sold up to 21½c. The U. S. Geological Survey has issued a report on copper in 1914. The 'Press' of next week will have this in full. Stocks on January 1, 1915, were estimated at 173,640,501 pounds.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date		Average week ending	
Apr. 22	50.50	Mch. 17	51.18
" 23	50.62	" 24	50.33

June	56.43	....	Dec.	49.27	....

Silver is firm, with a tendency to steady advance. On April 24 about 900,000 oz left San Francisco for the Orient. Exports from England to Asia up to April 15 were approximately 5,000,000 oz. less than in this period of 1915. Stocks in London are about £1,600,000 (16,000,000 oz.). India has been a disappointing factor in the market lately. Full power supply is available at Cobalt. This will increase the output. The Nipissing continues to ship to New York. On February 28 the Tonopah Mining Co. had metal stored worth $609,162, say 1,200,000 oz. Samuel Montagu & Co., of London, publishes the following regarding imports of silver from the United States on the first quarter of 1915 and 1914, in ounces:

	1915.	1914.
January	8,056,225	6,679,661
February	7,936,593	4,694,175
March	5,266,737	5,311,613
Total	21,259,555	16,685,449

As the syndicate which took over the India Specie Bank was selling its stock of silver early in 1914, this probably deterred the United States from selling freely in that quarter. Mexican supplies, considerably reduced, are included in the above totals. Exports from Canada in the first quarters of the two years were 4,133,619 and 4,449,947 oz. respectively. In spite of the increased total imports the price has been on an ascending scale, even though a great shrinkage in trade demand has taken place as a consequence of the War. The fact suggests that the market as a whole stands on a sound footing.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date		Average week ending

May	33.29	....	Nov.	33.51	....
June	30.72	....	Dec.	33.60	....

Tin is steady at 40 to 42c. April movements are discussed on the next page of this issue. In London the price is £163 10s. per ton.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Mch. 31	80.00	Apr. 14	80.00

It is reported that sales were made in London on April 28 at £67 per ton, equal to 16.75c. per lb. The excited market in the United States is solely due to exports for war purposes. Ore at Joplin advanced to $65 per ton, choice lots to $68. Stocks of ore have been reduced to 9000 from 13,000 tons.

New York Metal Review

The war demand for copper and spelter is growing. Both metals seem to be sharing this relatively equally. Most of the business does not involve export of raw metals, but of munitions of war in which they are used. Of the $83,000,000 order for shrapnel that was placed with the Canadian Car & Foundry Co. recently, many millions in sub-contracts will be divided among 40 concerns in the United States. Copper, spelter, lead, and antimony are all required in these death-dealing devices. The domestic demand for copper continues below normal. Lead, for some reason, has weakened in London, with a corresponding effect in this country. Spelter is strong and quotations are near 12c. again. Dealers in tin are nonplussed by England's strict control of the supply. English brands of antimony continue scarce and nominal.

Business in general shows many indications of improvement. One is the announced intention of the Pennsylvania Railroad Co. to spend $20,000,000 in rolling stock. The Lehigh Valley company will spend $1,000,000. Several railroads have issued lists of machine-tools and other shop equipment. Some of the lines have agreed to publish their requirements, rather than let them leak out through mill and selling representatives. Exports of finished and semi-finished steel are increasing in volume. Many machine-tool manufacturers cannot promise delivery on new orders before August. Pig-iron furnace stocks, taken as a whole, have decreased since the beginning of the year. The entire situation is one to inspire optimism. Exports in March from New York to all foreign countries amounted to $126,904,534, against $71,136,061 in March 1914, an increase of over $55,000,000. The imports at New York in March totaled $90,473,231, against $102,200,786 in March 1914, a decrease of $12,000,000.

COPPER

The war demand for copper in April was enormous. This might be expected, in view of the large contracts placed here for ammunition, shrapnel, lyddite shells, and other munitions of war. On every shrapnel case is shrunk a band of copper. A great deal of the metal will go into the drawn shells that contain the charge which throws the shrapnel shell from the gun. Exports for the month promised to be small, as up to April 23 they totaled 11,341 tons. As indicated, however, a large quantity of copper will soon be going abroad under some other name. Both Lake and electrolytic shared the demand. Their quotations moved upward steadily. On April 1 prime Lake was quoted at 17c., and April 6 17.25c. cash, New York. A heavy business was done. On the 13th Lake touched 17.75c. cash, New York. From that day on there were daily advances until, on the 20th the quotation was around 20.50c. for prime metal. Of course, the less favored brands were sold one or two cents lower. Choice brands easily commanded 21c. The month opened with electrolytic at 15.87½c. cash, New York; but on the 7th there were good sales on the basis of 16c., delivered in the Naugatuck valley, 30 days. On the 12th there were further large sales at 16.25c. cash, New York, and from that day on the entire program was one of advance. On April 20 the quotation was 17.37½c. cash, New York. There was some business April 22 at 17.62½c. cash, New York, but activity quieted down as a result of the rapid rise in prices. The trend of the market is illustrated by the advances in the base price of hot-rolled sheet-copper, as announced by the Ansonia Brass & Copper branch of the American Brass Co., as follows: April 8, base price, 21c.; 13th, 21¼c.; 14th, 21½c.; 17th, 22c.; 19th, 22½c.; and 22nd, 23c. Exports in March reached the total of 30,148 tons, compared with 15,583 tons in February and 26,193 tons in January. Exports in March 1914 were 46,504 tons.

LEAD

For about the first 10 days of April lead was strong under foreign influences. The situation caused the leading interest to advance its New York price on April 1 to 4.20c. At St. Louis, independents quoted 4.12½c. Large export inquiries were reported. It was generally accepted that a premium of at least $2 per ton was asked on export sales. On the 12th, however, London showed marked weakness, and on this side the market became heavy. Up to the 21st, the New York price was unchanged at 4.20c. St. Louis had weakened to 4.10c. The decline in London brought the quotation there down to £20 7s. 6d. on the 16th. The domestic demand has not revived to any noteworthy extent; in fact, it is disappointing. Consumers seem inclined to await events. This has brought about more pressure to sell from the middle of the month on. Exports, up to April 23, totaled 3613 tons.

SPELTER

There was another spurt in spelter prices in April. The metal from the first of the month had been steadily gathering strength, until about the 21st, the market showed excitement again, and spot prime Western was quoted at 11.87½ to 12c., New York. Choice brands were nominal at quotations up to 20c. It was commented that never before had spelter been quoted higher than copper. At all times exact quotations were difficult to obtain, but those of April 1 averaged about 9.50c., New York, and 9.25c., St. Louis. Domestic consumers were known to be short of the metal. Producers were in a sold-up condition. Would-be buyers were more in evidence than sellers. Future deliveries partook of the strength of spot. At St. Louis, May was quoted at 11c., and June at 10½c. on April 23. The month's exports up to April 23 totaled 3324 tons.

TIN

Dealers in tin were in a quandary in April. They are not yet out of their troubles. The extreme restrictions placed on shipments by Great Britain aroused the ire of many importers here. Not only has it been stipulated that the English shipper must be licensed, but also that dealers here must fill in a formal blank indicating the ultimate destination of the metal. From the consumer they must get another formal declaration stating that he will use the metal for his own manufacturing purposes, and not export the tin directly involved, or any other tin, except to Great Britain or her possessions. The first effect of this procedure would be to restrict business among dealers. It also would interfere with the supplying of retailers. The latter distribute about 20% of the tin which comes to the United States. It was further stipulated that tin arriving unsold or on consignment should go into the safekeeping of the banking firm of J. P. Morgan & Co., who are to collect ¼ of 1% of the value of the importations for their services, pending a delivery of the metal satisfactory to the British government. The entire situation is brought about by the fact that through neutral countries, Germany has been supplied with tin. About the middle of the month a committee of the New York Metal Exchange called on Sir Richard Crawford, special agent of the British government at Washington, and appealed for relief from the drastic regulations. Practically the only satisfaction they obtained was that some way would be found to place small quantities in the hands of retailers. It was pointed out that the operations of a large plant might be held up by the lack of a comparatively small amount of the metal. Sir Richard made it clear that Great Britain will not allow any accumulation of spot tin in this country. Through the month business was almost entirely confined to small lots of spot. Up to April 23, 1930 tons had arrived, but there were prospects of relief when arrivals from the Far East became available. Three vessels arrived April 20, but all put in at Boston, where they were delayed a few days. War prices were reached again. The quotation on April 9 was 58c. After that there came daily declines until 46.50c. was reached April 20 and 41.50c. on April 22. The downward trend was due to the easier feeling that followed the reporting of the vessels referred to. Deliveries for three months of 1915 were 8875 tons, or 2475 tons less than in the same period of 1914.

Current Prices for Oils and Candles

(Corrected monthly by Standard Oil Co., California.)

All prices are f.o.b. San Francisco except where otherwise specified, and are subject to change without notice.

Granite Mining Candles.	Per set. cents.	Granite Mining Candles.	Per set. cents.
6s-12 oz.-40s	8¾	6s-14 oz -20s	9½
6s-12 oz.-20s	9	6s-16 oz.-40s	10
6s-14 oz -40s	9¼	6s-16 oz.-20s	10¼

Extra hard 1c. per set higher than the above.

The following prices are for oils (Calol) in wood barrels; cases (2-5 gal.) 3c. per gallon higher.

	Per gal., cents.		Per gal., cents.
Compressor oil	40	Light gas engine oil	28

Zinc shavings, 850 fine, bbl., per 100 lb.	17.50	....
Zinc sheet, No. 9—18 by 84, drum, per 100 lb.	No quotes	

*Extra charge for packing nitric acid for shipment to conform to regulations.

Roessler & Hasslacher quoted as follows April 13:

Ammonia, anhydrous, in 50-lb. cylinders, per lb	$0.27
Arsenic, white powdered, in 500-lb. bbl., per lb	0.05
Cobalt oxide, black, in 10-lb. tins, per lb	1.05
Cyanide, potassium, 38.4% cyanogen, per lb	0.27
Cyanide, mixtures, potassium cyanide equivalent 39.5% cyanogen, per lb	0.20
Sodium, metallic, in 1-lb. tins, per lb	0.40
Zinc dust, in bbl. 1600 lb	0.12

Since the last report general conditions in chemicals have not changed. Certain stocks are low, and prices of a number of chemicals have increased.

MINING DECISIONS

Oil Lease—Forfeiture Denied

Equity will refuse to enforce a forfeiture, at the suit of a lessor, based on locations of oil-wells by the lessee at points different from those prescribed in the lease, where, with knowledge thereof, the lessor has accepted his share of the production therefrom and the lessee has spent considerable sums in a *bona fide* attempt to develop the property.

Horse Creek Coal Land Co. *v.* Trees (West Virginia), 84 Southeastern, 376. February 2, 1915.

Notice of Patent Application—Posting

Section 2325, Revised Statutes, contemplates that notice of an application for patent for a mining claim shall be posted within the exterior limits of the area applied for; and the posting of such a notice outside of a claim and 800 ft. distant therefrom, is not such a substantial compliance with the requirements of the law as will warrant submission of the entry to the Board of Equitable Adjudication.

Equity Mining and Investment Co. (Land Department), 43 Land Decisions, 396. September 19, 1914.

Oil Lease—Condition Construed

Where a six months' lease of land for sinking oil-wells was conditioned that a well must be sunk which would produce a given quantity per day and for a given time, before it was to be considered a paying well so as to give the lessee a permanent lease, the lessor had the right to cancel the lease on a failure of any of the driven wells to produce the contract quantity in the time limited, though they did produce a paying quantity.

McLean *v.* Kishi (Texas), 173 Southwestern, 502. January 8, 1915.

Coal Lease—Held Merely an Option

A coal-mining agreement to lease seven parcels of land, with different time limits, conditioned on payment of royalty for coal mined, providing that it was not compulsory on the lessee to exercise any rights on the lease, that the lessee was to incur no damages for non-performance, that if he elected to work under the lease he should mine the coal under certain land first, was held to be an option requiring notice of election in order to be binding on the lessee.

Ray Coal Mining Co. *v.* Ross (Iowa), 151 Northwestern, 63. February 20, 1915.

Mining Corporations—Income Tax

A mining corporation which had leased all of its ground for mining purposes long prior to 1909, when the Federal income tax law took effect, and after that date only continued to receive royalties from such leases and to distribute the same among its shareholders, is not receiving an income subject to the Federal tax, but merely that which was in effect the purchase price of lands sold long prior to the date on which the tax act became effective. In other words, the return of a part of its capital investment, it appearing that the lands were of no value except for the ores in them. The word 'income' in the Act is not synonymous with the word 'receipts', and does not include receipts from the conversion without gain or profit of any part of the property of the corporation into money, or other form.

Von Baumbach *v.* Sargent Land Co. (Minnesota), 219 Federal, 31. December 9, 1914.

Revision of the Tertiary Mollusca of New Zealand. Based on type material. Part I. *Paleontological Bulletin* No. 2. By Henry Suter. P. 64, and 16 plates. New Zealand Geological Survey. Wellington, 1914.

Höganas Iron Sponge. Its use in the manufacture of steel and iron. P. 11. Illustrated. Höganäs-Billesholms Aktiebolag. Höganäs, Sweden. This is a comparatively new product, and is exhibited in the Sweden building at the Exposition.

Some Deep Borings in Illinois. By J. A. Udden. *Bulletin* No. 24. P. 141. Plans, index. State Geological Survey of Illinois, Urbana, 1914. The well records show interesting strata passed through, and the drilling has been of great value in geological investigations.

Peat, Lignite, and Coal. Their value as fuels for the production of gas and power in the by-product recovery producer. By B. F. Haanel. P. 261. Ill., plans, maps, index. Department of Mines, Ottawa, Canada, 1914. One of the problems in Canada is the rendering available of the various supplies of low-grade fuels, and this study describes what is being done in Germany, and what is suitable for Canada.

British Columbia Bureau of Mines bulletins, Victoria, 1915:

Mineral Resources of the Atlin Mining Division. By W. M. Brewer. No. 2. P. 24. Illustrated.

Mineral Resources of the Skeena Mining Division. Also portions of the Onimeca and Queen Charlotte divisions. By W. M. Brewer. No. 3. P. 56. Illustrated. Recent issues of the *Press* have contained notes on these districts.

Water Supply, Sewerage, and Drainage in Western Australia. Second annual report, 1913-14, of the Government department controlling these public utilities. P. 104, with numerous illustrations, maps, and plans. Perth, 1914. The Government in this state operates the principal water supplies of the towns, including that of Perth, and the great goldfields system with a main 353 miles in length. The engineers' reports are of great interest, and abstracts will be made for other issues of the *Press*.

New Machines and Devices

Information based on letters and catalogues from manufacturers.

Engineering Specialties at the Panama-California Exposition

As will be seen from the accompanying picture, the Lunkenheimer Co., of Cincinnati, Ohio, has a neat and attractive exhibit at the Exposition being held at San Diego, California. 'Quality' is the watchword of this concern, this being apparent after an inspection of its products.

In great variety are displayed bronze, iron, 'puddled' semi-steel and cast-steel globe, angle, cross, check, gate, non-return boiler stop and throttle valves; also bronze and iron pop-safety, relief, and blow-off valves; water columns and gauges; whistles; ground keywork; injectors and ejectors; bronze fittings and unions; cylinder lubricators, oiling devices, oil and grease cups; automobile and motor-boat specialties, and other specialties.

LUNKENHEIMER SPECIALTIES AT THE EXPOSITION AT SAN DIEGO.

Commercial Paragraphs

A price list of oil and gas well 'lines' or steel ropes has been published by the HAZARD MANUFACTURING Co., of Wilkes-Barre, Pennsylvania.

The BURD HIGH COMPRESSOR RING Co., of Rochester, Illinois, announces that it has moved its general and executive offices to 307-309 South Main street.

L. F. HAMILTON, in charge of the advertising and specialty department of the NATIONAL TUBE Co., has returned from an extended business trip to the Pacific coast in connection with the company's exhibit at the Panama-Pacific Exposition. The display is part of the United States Steel Corporation's exhibit. This is in the Palace of Mines and Metallurgy. It occupies 44,000 sq. ft., the largest single exhibit at the Exposition.

A new electrically-driven combination swing and rip-saw has recently been perfected and will be manufactured by the RENO-KAETKER ELECTRIC Co., of Cincinnati, Ohio. Both units are independent of one another, it being possible to use them either in combination or at different parts of any work. Both of these outfits are especially suited for mines, for cutting timbers and lumber used extensively in mine-shaft construction.

The Interstate-Callahan Mining Co. has let a contract to the AMERICAN STEEL AND WIRE Co. for the construction of a 10,500 ft. aerial tramway from its mill to Sunset station, Idaho, on the Nine-Mile branch of the Northern Pacific Railway, in the Coeur d'Alene. Work will begin about April 20, and it is expected that the line will be ready to operate not later than May 15. An engineer for the construction company will be in charge, and between 75 and 85 men will be employed. The Interstate-Callahan tram will be the longest in the Coeur d'Alene, and the second longest in the West, the only longer one being a 13-mile system at Saline, California.

The HOLT MANUFACTURING Co., of Stockton, California, states that some of its Caterpillar tractors are being used in the following work: saving $100 per ton in hauling dredge machinery, 65 miles out of Nome, Alaska, the cost being only $20 per ton; hauling ore at Lordsburg, New Mexico; hauling rock for the California state highway, and hauling wool over rough roads near Golconda, Nevada.

The SULLIVAN MACHINERY Co. of Chicago has sent us two new bulletins, No. 65-C and 71-A. The former deals with their diamond core-drills, giving estimates, equipment required, and prices. The cost of these installations varies from $555 for the 'M' hand-power rig to $12,869 for the 'PK' steam or air-drive for deep prospecting. This standard machine is well and favorably known. Air-lift pumping is the subject of the other bulletin, and among the advantages of this system the following are claimed: quantity and quality of water increased, temperature reduced, durability and simplicity, and sustained efficiency.

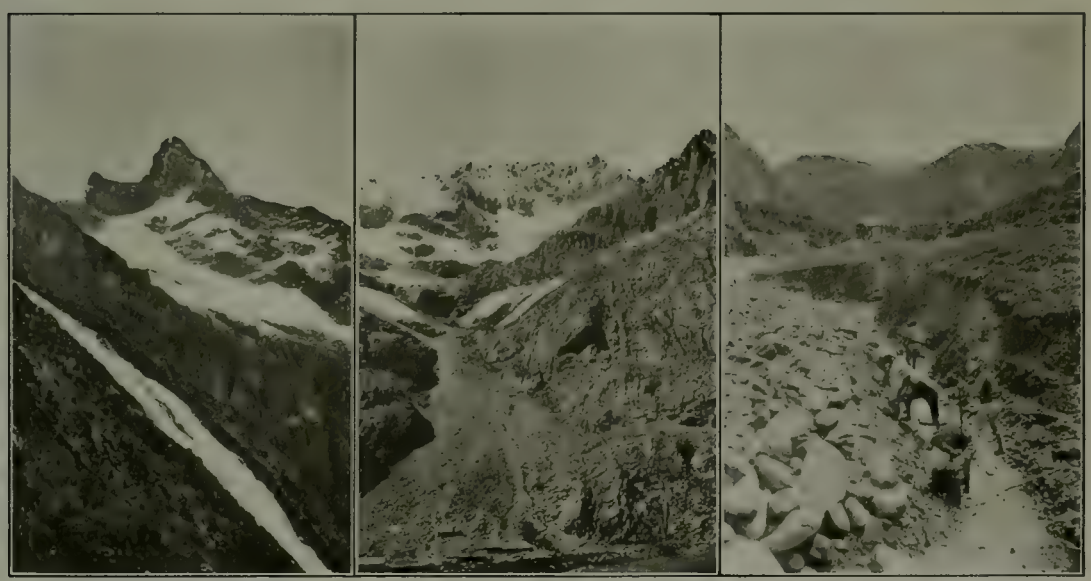
The POWER & MINING MACHINERY Co., 115 Broadway, New York, reports that it has built a 60 by 84-in. receiving opening jaw-crusher for the Bethlehem Chile Iron Mines Co. It is sectionalized to a 30,000-lb. limit to facilitate handling at its destination. The total weight is 525,500 lb. The service in this instance is particularly severe, as the compressive strength of Tofo iron ore is nearly 44,000 lb. per sq. in., compared with hard trap-rock of the United States estimated at between 35,000 and 40,000 lb. Following this crusher and taking the 10-in. product from same, there will be installed three No. 9 McCully all-steel gyratory-breakers. A 66 by 84-in. machine was recently completed. Five years ago the Birdsboro Stone Co., Birdsboro, Pennsylvania, installed one of these crushers. About 2,000,000 tons of trap rock has been reduced. The only expense for repairs was the renewal of the lower row of crushing plates.

Mining and Scientific Press

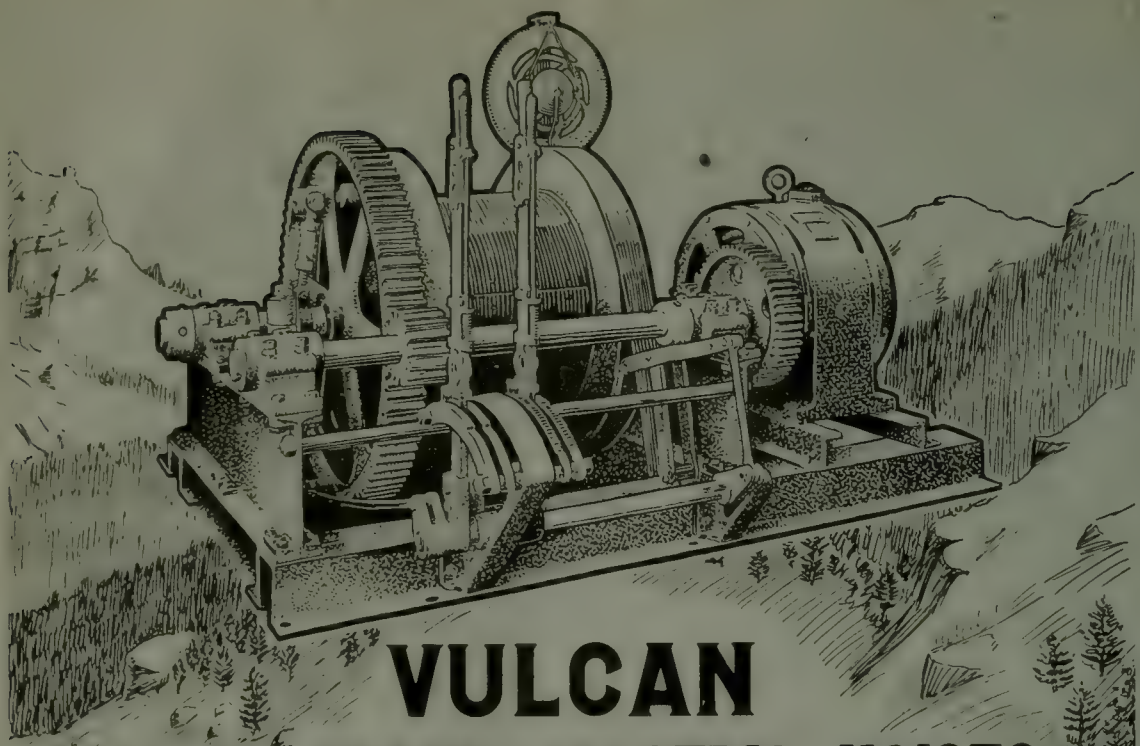
Edited by T. A. RICKARD

Volume 110 SAN FRANCISCO, MAY 8, 1915 Number 19

TIN is much in demand. The price has risen from 31 cents per pound in July to 57 cents per pound in April. The United States consumes 50,000 tons per annum and produces only 50 tons, chiefly from Alaska. Even the Bolivian ore goes to Europe to be smelted, the

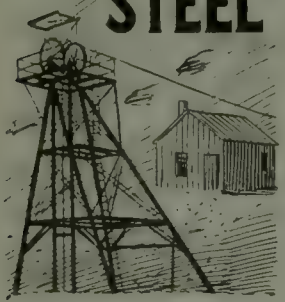


tin being returned to this side for the manufacture of tin-plate, bronze, and tin-foil. A good tin mine would be a sweet business today. The prospector should keep his weather eye open for that useful metal. Meanwhile we publish a description of Quimsa Cruz, one of the Bolivian districts, to indicate the conditions favorable to tin deposits.



VULCAN
STEEL FRAME ELECTRIC HOISTS

Have Many Advantages Over the Solid Cast Frame Hoist



The frame is stronger and stiffer, the weight is one-third less, easily knocked down, convenient to assemble. Just the thing for mule-back transportation. It can be taken underground to any level and assembled easily. Freight charges are less.

NOTES 711

COST AND EFFICIENCY 711
A review of the factors of true cost.

ADMINISTRATIVE CONTINUITY 712
An excellent policy in mining.

JAPAN AND CHINA 713
Observations on the Far Eastern situation.

PETROLEUM CONSERVATION IN CALIFORNIA 714
Wise legislation is about to be enacted.

DISCUSSION

PLUMBING A SHAFT.
By James A. Walker and R. T. Crawford 715
A correspondent inquires as to the effect of the moon's pull on a plummet, and the assistant astronomer at the University of California gives the facts of the case.

RESEARCH FOR ENGINEERS.
By E. Gybbon Spilsbury 715
The Library of the United Engineering Societies has arranged to investigate any desired subject at a small cost.

RISE OR RAISE?
By L. S. Ropes and A. L. Horner 715
More discussion as to the right use of words.

THE CRACKING OF OILS.
By E. I. Dyer 717
The chief engineer of the Union Oil Co. explains the limitations of the process.

ARTICLES

COST AND EFFICIENCY.
By Heath Steele 718
Mere figures as to cost are not sufficient for comparative study, since the unit cost may differ and a property which uses fewer units may show a greater total because the unit cost is higher. Suggestions are made as to the collecting of data that will make exact comparison possible.

QUIMSA CRUZ TIN DISTRICT, BOLIVIA.
By Francis Church Lincoln 721
The tin deposits of Bolivia extend for 400 miles along the main range of the Andes. In a recent issue the Milluni district was described, the Quimsa Cruz district adjoins that on the south. The deposits are described and details of working cost are given.

QUANTITATIVE BLOWPIPE ANALYSIS IN THE FIELD.
By George Delius 725
The transporting of samples of gold and silver ores for long distances to have them assayed can be avoided if the prospector is sufficiently skilled in the use of the blowpipe. A surprising degree of accuracy can be attained, and the advantage of securing quick returns is evident. A skilled operator describes the equipment and the methods to be followed.

LABOR-SAVING DEVICES.
By S. A. Worcester 727
Minor automatic devices can be made to save the labor of one or more men about a mill. Regulators for mill pressure, air-lifts, and zinc-dust feed, a pump-control, indicators for storage bins and pump discharge, and a tell-tale for belt-conveyors are all described.

METAL PRODUCTION IN JAPAN IN 1914 729
Gold production for the past year was $4,476,500; silver, 4,647,767 oz.; copper, 139,676,531 lb.; coal, 21,695,071 tons; sulphur, 150,548,300 lb.; and petroleum, 2,936,240 barrels.

NEW SYSTEM OF MINING COAL AT DAWSON, NEW MEXICO ... 730
Hereafter entries will be driven to the boundaries before turning rooms, recovering all the coal in one operation and securing the advantages of long-wall working. To prevent dust, tight cars are to be used, and moisture radiators are installed at the entrances.

MINING COSTS AT GOLDFIELD CONSOLIDATED 730
Details of all the items making up the total mining and milling cost are given.

CYANIDE PLANT OF THE CHIKSAN MINES, KOREA.
By Charles W. De Witt 731
The ore is crushed to 30-mesh by stamps, run over amalgamating-plates, and concentrated on Standard tables. The table tailing is leached in vats that are filled and emptied by coolies. The solution is precipitated on zinc shaving. During the past year the recovery was 80c. per ton of tailing, at an operating cost of 33½c. per ton.

NEVADA MINERALS AT THE EXPOSITION 735
The exhibit of Nevada minerals is well arranged and instructive.

MINERALS OF NEW ZEALAND AT THE EXPOSITION 735
Agriculture is more important than mining in New Zealand; nevertheless a good mineral display has been made.

ELECTRIC SHOVELS

WHY
Pay for Hauling Coal
When Electric Power Transports Itself?

Electric Shovel Equipped with G-E Motors.

Increase profits by equipping your shovel with G-E Motors. Labor charges can be reduced 30%, repair bills cut in half and boiler and feed water trouble avoided.

No firemen and fire banking are necessary, nor is it necessary to leave a watchman on the job.

Electric shovels operate like a steam shovel and equal or surpass it in every respect.

The General Electric Company makes a complete line of motors for this service. Its recommendations are based on years of actual experience with existing electric shovels and on a thorough knowledge of shovel operation.

EDITORIAL

T. A. RICKARD - - - - Editor THOMAS T. READ - Associate Editor

COPPER MINING in the Southwest is now within 10% of its pre-War activity.

UNEMPLOYMENT in the mining centres is disappearing like the winter snow.

EXTRA taxation of the mining companies of the Rand is a logical consequence of the War, especially the operations of the Union Government in German Southwest Africa.

ANGLO-AMERICAN enterprise in Siberia is making good progress, despite the War. Labor supplies are improving, so that exploratory work is increasing. The embargo on vodka has improved efficiency remarkably.

ACCORDING to *The Mining Magazine*, the terms on which the Broken Hill Proprietary and the Sulphide Corporation have sold zinc concentrate to the American smelters are not so encouraging as to presage a large business in that product.

GUANAJUATO has been made to feel the heavy hand of revolution. During the last three or four weeks it has become the arena of conflict between the Carranza and Villa insurgents. The railway service has been so disrupted as to compel cessation of mining operations.

AMONG those rescued from the *Falaba*, which was sunk by a German submarine on March 29, were four engineers, namely, Messrs. Allan A. Davidson, A. Goldwater, H. I. Johnson, and F. P. Barker. Among those lost was Leon C. Thrasher, as we recorded in our issue of April 3.

MEXICAN PETROLEUM shares have had a big rise in consequence of the contract between that company and the British Government. This seems to involve a sanguine disregard of sundry unpleasant possibilities. If and when a stable government is restored in Mexico it will become necessary to raise revenue for the rehabilitation of the country; and when that happens, it is to the prosperous oil industry that the tax-gatherer will turn. An export-duty on oil is a possible eventuality. As a counter for a gamble, Mexican Petroleum has obvious attractions, but as an investment it appears unduly risky at the present time.

FRANCISCO VILLA, otherwise Pancho Villa, alias Doroteo Arango, alias Doroteo Castañeda, is being pushed to the wall by the Constitutionalist or Carranza faction in Mexico. His defeat at Irapuato, the repulse of his associate General Filipe Angeles at Celaya, followed by the retreat of General Maytorena, Villa's governor of Sonora, from Navajoa, indicate that the so-called Convention party is losing its hold on the northern region.

COPPER continues to rise. It may go to 25 cents. The war orders placed in this country during the last 10 days are enormous. Contracts running into millions of dollars have been placed with the Canadian Car & Foundry Company, the American Locomotive Company, the Crucible Steel Company of America, the Westinghouse Air-Brake Company, the New York Air-Brake Company, and other gigantic orders are pending. Besides there are thirty or forty concerns working on sub-contracts. All this will mean an increased and sustained demand for copper and spelter. The makers of the machines required to turn out shrapnel, lyddite shells, and projectiles are sold up to next August and September.

Cost and Efficiency

In this issue we publish a thoughtful article by Mr. Heath Steele on the factors determining the cost of mining operations. An analysis of this kind is a great help toward forming a clear idea of the realities underlying the making of money by the extraction of metal from the ground. Even in an industrial centre like Johannesburg, and despite the co-operative activity of a community of engineers, it required several years of misdirected effort to bring home the truth that economic success is measured not in the cost per ton but the profit per ton. It remains yet for many engineers and operators to appreciate the fact that ultimate profit may be

sacrificed to the profit per ton. The purpose of mining is to make a maximum ultimate profit in the form of dividends or liquid assets. In order to further the technical value of cost records, it is imperative, as Mr. Steele indicates, to use an intelligible basis of comparison. The cost of living, for example, at any time or place, is based upon the price of the primary staples, these being accepted as an index to all the secondary expenses of mankind. To compare the cost of living in terms of house-rent, for example, would be misleading, for rentals are not levied on any common basis in various countries or even localities. Similarly, the cost of clothes would furnish no reliable criterion, nor even the average wages. The unit of measure must be one applicable under varying conditions. So in mining, the dollar does not suffice for purposes of comparison; we must have the cost expressed in something nearer the base of the industrial problem, namely, the energy and material consumed in the operations. Mr. Steele gives a list of items required to make an intimate comparison between mines. Not all of these details may be available, but without some of them it is impossible to make any intelligent comparison. Thus it is not the average wage, but the average tonnage of ore broken per day per man that gives the relative efficiency of the labor employed. It is not the cost of development per foot, but the cost of development per ton of ore developed that indicates the expenditure required to maintain the vitality of a given mine.

As regards the making of intelligible statements of cost, it may be taken that the first requisite is the desire to give information. If there is one way of stating facts clearly, there are a hundred ways of obscuring them in figures and in words. The reports of mining companies afford constant illustration of the adage that "Speech was given to man to conceal his thoughts." The same is true of figures, for did not Disraeli say that there were three kinds of lies: "Lies, damned lies, and statistics." The copper statistics issued on both sides of the Atlantic during the contraband controversy last November may be instanced. One could prove anything from them according as the periods and the countries involved were selected or combined. Some mining companies issue no detailed report, others give a cloud of figures from which no real information can be precipitated. The cost, especially among British companies, is often a nebulous figure representing an intermediate stage of book-keeping. This brings us to the assertion, once more, that the real cost of mining is the value of the product less the money distributable to the owners of a mine. Dividends may not be the whole measure of the profit, for part of the surplus may be re-invested, but in the end it is only the money that is placed to the shareholder's credit at his own bank that is profit to him; the rest may be deferred or anticipated, but it is not truly his until he places his own hands upon it. That is why the term 'operating' or 'working' cost must be used carefully. It should mean the total cost at the mine, the whole expenditure coming under the immediate cognizance of the resident manager, but it should never be allowed to masquerade as a final accounting. Taxes, general expenses, directors' fees, insurance, and the like are as much a part of the expense of mining as is the cost of dynamite and drills. In most American mining enterprises the 'working cost' is within 5% of the total cost, but in some Rhodesian mines, for example, it is 30% short of the reality. Obviously, the 'working cost' should be used, like the daily assay-sheet, as a guide for the management and not as a figure to express the final economics. Figures of cost, whether the total or in detail, should serve as a spur to efficiency, which is the right application of power, mental and mechanical, for the achievement of the purpose in hand. In mining, the purpose is to make a maximum ultimate profit by extracting metal from underground.

Administrative Continuity

Fortunately or unfortunately, depending upon the point of view, most men outlive most mines. A manager may hope, or may regret to expect, to direct the operation of several mines successively in the course of his career. Again, good managers are at least as scarce as good mines. Manifestly, it is economic not only to select an efficient manager, but to keep him continuously employed. What is true of him as an individual is even more true of the management or administration as a whole, for a number of technical men working as a unit under their chief constitute an asset not to be liquidated in a hurry. Such are the ideas suggested by the policy to be inferred from the corporate acts of several of the best known mining companies in Nevada. The Goldfield Consolidated recognizing, we presume, the proximate exhaustion of its group of mines at Goldfield, has acquired the control of the Aurora Consolidated and is about to begin the systematic exploitation of that old property. The Tonopah Mining Company has recently acquired the Reliance and other dredging properties at Breckenridge, Colorado, besides exercising its option on the Eden mine, in Nicaragua. The Tonopah Belmont Development Company has just announced the acquisition of an option on the Potosi mine, in Nicaragua, near the Eden mine of the Tonopah Mining Company. In addition, the Tonopah Belmont has under option a mine at Surf Inlet, in British Columbia, and the Oro Belle mine at Hart, in California. The Montana-Tonopah Mining Company is largely identified with the control of the old Commonwealth mine in Cochise county, Arizona, and the Black Oak in Tuolumne county, California. These examples suffice to indicate a trend of policy. The operators or capitalists controlling these companies see the wisdom of retaining the services of a competent and experienced staff; they recognize the fact that the original property, for the working of which their company was formed, is destined to be exhausted, sooner or later; so they preserve the asset that wastes less slowly, namely, the technical skill of a well-organized administration. Most of them have scouts on the

look out for likely new mines, to supplement the properties already under option and in process of being tested. We commend this policy. It is wise. It conserves a valuable asset: the *esprit de corps* of a staff. It renews the vitality of a corporate enterprise. It prolongs the fruitfulness of capital. It prevents that worst of all waste, the waste of experience.

Japan and China

Out of the deplorable War now raging has arisen much confusion of ideas as well as disruption of international commerce. Official statements, papers white, blue, and gray, have been published, setting forth the conditions leading up to the War, and writers of every nationality, degree of prejudice, absence of balance, and lack of insight have given us the benefit of their opinions as to its causes and effects. Amid this babel of conflicting tongues the United States as a nation has remained officially neutral, while our people have also remained as neutral as men with red blood in their veins can be when they see their fellows revert to the habits of the jungle. In this country there are millions of estimable citizens of German descent, or affiliation, many of whom have felt aggrieved that there appears to exist here so little sympathy with the German cause. It is not, however, a matter of sympathy; it is a matter of unimpassioned belief as to which side is in the right. Stripped of all its confusing adjuncts the central fact of the German cause is a biological philosophy of life, a philosophy that projects the theory of a struggle for existence and the survival of the fittest into all human relations. This includes the idea that the strong and efficient will necessarily overcome or displace the weak and inefficient; therefore weakness and inefficiency should be swept away. Against this is set the ethical philosophy of life, which maintains that while man is indeed a biologic organism he differs from all other forms of animal life in being also a psychic organism, and that the latter is the higher factor. Animals know neither right nor wrong, they act in response to the stimuli of their environment. The fox catches and eats the rabbit in response to the stimulus of hunger; the powerful landowner is restrained from appropriating the poor man's fertile garden by ethical considerations that, in the abstract, at least, the whole world approves. Civilization recognizes the right of the weak to exist. Human slavery was based on the biologic view of life, which accords to the strong man dominion over the weak; the struggle for freedom that has characterized human history for the past thousand years is based upon the assertion that such a view of life is fundamentally false. Linked with this is our refusal to accept the biologic criterion of what constitutes weakness and inefficiency. From the gladiatorial viewpoint the life of a Christ who lived without home or property, who taught consideration of others, and who died on a cross, was a pitiful failure, but the majority of men acclaim it as a splendid triumph. It is for this reason that the American public as a whole, without depreciating the German contribution to science or the German gift to art, or the splendid record of German efficiency in the organization of business, is convinced that the German philosophy of human relations cannot be accepted. When the War ends, as we hope it may soon, there will be one great compensation for its destruction of life and property if it shall have established that the modern world will not accept the biologic concept of human relations.

Preoccupation with what is happening in Europe has been so great that our public is largely unaware that a nation adhering to the biologic philosophy of life is becoming the dominant factor in Asia also. The marvellous increase in the power, wealth, and influence of the German nation, which in little more than a century has arisen out of a group of warring kingdoms, is surpassed by the astonishing rapidity with which Japan has emerged from a collection of petty feudal dukedoms into a modern nation of wonderful efficiency, energy, and power. The method pursued in both cases is the same. Centralization of government in an autocratic emperor, representative institutions without democracy, the subordination of the citizen to the State, and the directing of national life along lines planned by the Government have combined to produce the astonishing result. Japan, even more than Germany, adheres to the gladiatorial theory. With a small area of country, limited resources, and a growing population it sees the assurance of its future only in the extension of dominion over weaker and less efficient peoples. Formosa, Korea, and southern Manchuria have been absorbed; now the little brown hand reaches out to the whole of China. In all that has happened in the past six months a definite purpose and plan is evident, as a brief review of events will show. On August 15 the Japanese government sent to Germany a demand for the delivery to her "without condition or compensation, of the entire leased territory of Kiaochou, with a view to the eventual restoration of the same to China." Some doubt having been felt in America as to the exact meaning of this phrase, Count Okuma sent for publication in this country the following statement: "As Premier of Japan, I have stated and now again state to the people of America and of the world that Japan has no ulterior motive, no desire to secure more territory, no thought of depriving China or other peoples of anything they now possess." Meanwhile Kiaochou had been blockaded and preparations were in progress for a land attack. A start was made to place troops within the leased territory, but the plan was suddenly revised, and the forces were sent to Lung-kou, a small port on the inner side of the peninsula of Shantung, involving the marching of Japanese forces through 150 miles of Chinese territory. China at first protested, then 'saved her face' by declaring this territory a warzone in which belligerent operations might proceed. As a gross violation of neutrality the action of Japan was on all fours with the invasion of Belgium, the only difference is that in the latter case a brave and warlike people stubbornly resisted the violation of their rights, confident in the hope of aid from other nations that do

not subscribe to the biologic theory. China saw no hope of aid, and weakly yielded, in the hope of saving something from the wreck. In due time Tsingtao, the city of the territory of Kiaochou, fell. The Japanese seized not only the area, but the custom-house, which was Chinese, not German, and the railway from Tsingtao to Tsinan-fu, which was the property of a corporation. The purpose of Japan then became evident. A set of demands were made upon China that in tone and import are those of a conqueror to a conquered people. These have been widely published in full; they provide for extending the rights already acquired by Japan in China, the granting of fresh zones of influence, the placing of the police and other functions of government in sundry areas in Japanese hands, and the virtual surrender of Chinese autonomy. If these concessions had been made, China would have become a vassal of Japan. Many of the less important demands have been granted, in the hope of resisting the others. Meanwhile Japanese troops were moved into China, even into Peking itself, while the second squadron of the Japanese navy was sent to patrol the entrance to the Yellow Sea. The end is not yet, and it remains to be seen whether China will be obliged to surrender her national entity. The situation has been much confused by talk of trade and international influence, whereas it is simply one of right and wrong. Shall the rights of the Chinese people be respected, or shall they be grossly disregarded to allow free rein for progress and efficiency? Rivers of blood and millions of treasure are being poured out in Europe to establish the right of the weak to exist. In America we suffer patiently the murder of American citizens and the destruction of American property rather than interfere with the right of the Mexican people to misgovern their country as they will. In Asia the Chinese people, who have successfully established a republican government, put the revenues of the country on a sound footing, and are modernizing their institutions as rapidly as is practicable in an ancient democratic civilization, are falling under the iron hand of autocracy. This is not a matter that concerns only China and Japan, it concerns the whole world, it is a turning back of the hands of progress a thousand years. No nation is in a position to interfere except the United States, and this people that made no protest at the assassination of Belgium cannot be expected to make any move to uphold the hands of an alien people. But two points must be remembered. The Chinese have a racial entity paralleled only by the Hebrews. Throughout forty centuries Mongol, Tartar, and Manchu have swept down upon China, achieved political domination for a time, only to be slowly and silently forced back by the resistless tide of Chinese racial entity. Japan can hope to obtain no permanent hold over China. More imminent is the probable result of a national policy contrary to the spirit of the 20th century. This has been well expressed by Mr. Liang Chi Chao, who has recently said: "Japan succeeded because China could not retaliate. Indeed, the people of the world can do nothing to Japan now. But is it really worth while to purchase political ambition at the expense of leaving behind it a heritage of hate? Let the far-sighted statesmen of Japan bethink themselves long and earnestly." To this we may reply in the words of Carlyle that nothing based on wrong can hope to endure. The policy of the Japanese government, like that of the German government, is on the way that leads to destruction. It must be understood clearly that we are here criticizing governments, not peoples. Governments, like corporations, have no souls. Only the sense of honor of a people can curb the soulless diplomacy of a government. For those that disregard international law there waits a Nemesis. Political crimes eventually avenge themselves.

Petroleum Conservation in California

At various times in the past we have referred to the danger to which the petroleum industry of this state is subjected through allowing the underground waters encountered in drilling to find their way into the oil-bearing sand. One unguarded well may wreak havoc to many others adjacent, and it is only through concerted action that safety can be assured. The State Mining Bureau most properly has taken the lead in the efforts to bring about co-operation. During the past three years many conferences have been held and several bills drafted. None of these has yet been enacted into law, but by the discussion of them a better grasp of the factors involved has been attained, so that the present bill, now before the legislature at Sacramento, is a satisfactory measure. The funds necessary for administration are to be furnished by levying an equally distributed special tax on the properties producing oil. General supervision is to be in the hands of a commissioner of gas and oil wells, under the State Mining Bureau. He is to have control of the water problems in the oil-fields throughout the state, and is empowered to appoint deputies for the various fields. Appeals from the commissioner's decisions are to be heard by a board of three arbitrators, whose decision shall be final. The operators are more nearly united in favorable opinion of the bill than they have ever been on any of their other problems, and the enactment of the bill seems assured, since it has already been passed by both the Senate and the House, and will at once go before the Governor for signature. As Governor Johnson is understood to be favorable to the bill, he will undoubtedly sign it, and the law will go into effect 90 days thereafter. The bill provides for a sufficient salary for the commissioner to make it possible to secure a good man for that post, and it should be the duty of the petroleum operators to see to it that the office is not allowed to become one of the spoils of political patronage. Providing as it does for a just combination of local control and central supervision, the proposed law should prove both satisfactory and equitable in its working. It is to be hoped that this spirit of co-operation will continue to characterize the activities of the operators' associations.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Plumbing a Shaft

The Editor:

Sir—Having subscribed to your paper since 1893, I take the liberty of seeking your knowledge on the subject of deep-shaft surveying. Take the case of transferring a base line from the surface to the bottom of a vertical east and west shaft, 1000 ft. deep, by means of heavy plummets on the finest permissible wire. Would the varying declinations of the moon tend to draw the plummets from the vertical in an erratic manner according to the angle of the gravitational pull? Then again, should the shaft's longest axis be north and south, would the changing angle of pull of the sun's influence affect the alignment below, and to what approximate extent?

JAMES A. WALKER.

Brock's Creek, Australia, January 25.

The Editor:

Sir—The answer to both of Mr. Walker's questions is No. The reason for this is shown by the following considerations. The influence of the moon on the problem is greater than that of the sun, so we need to show only that the moon's influence is negligible. The expression for the deviation of a plumb-line due to the horizontal component of the moon's pull on a plummet is

$$3/2\ M/E\ \sin^2 p \sin 2z\ 206265''$$ (in seconds of arc)

where M and E are the masses of the moon and earth respectively, p is the moon's horizontal parallax, and z is the zenith distance of the moon. $M/E \sin^2 p = 1/17{,}800{,}000$, so that the angular deviation of the plumb-line due to the action of the moon is very approximately 1/60 of a second of arc times sin $2z$. The maximum displacement, therefore, that a plumb-bob at the end of a 1000-ft. cord could have would be 1000 tan 1/60″ (in feet), which is less than 1/1000 of an inch. This maximum would be for a zenith distance of the moon equal to 45°.

R. T. CRAWFORD.

Berkeley, California, May 1.

Research for Engineers

The Editor:

Sir—Your editorial in the issue of April 17, 1915, 'Mining Ventures in China,' appeals to me very much, owing to the fact that I am at the present time interested in the organization of a Library Search Bureau in connection with the combined libraries now known as the Library of the United Engineering Society. I have for a long time past felt that one of the chief aims of the library board ought to be in extending to the fullest possible degree the utilities of the library to the members and the public generally who have not the advantage of living in close proximity to it. This Library Service Bureau is now being organized so as to furnish to members, who desire to be kept posted on current literature, reference cards on any subject in which they may be especially interested.

Our library receives currently over 1000 periodicals, and has now 80,000 volumes on technical subjects. The Service Bureau has engaged the services of thoroughly competent searchers and translators, each one of whom is equipped with a thorough professional knowledge of the branch of engineering put in his care. An engineer who has registered a given subject on which he wants current information receives every two weeks reference cards giving the title, author, and exact citation of all articles appearing in the current literature on that subject, these cards being sent out at the nominal charge of 5c. each. The charges made for abstracting, translating, and photostat copies are moderate and should appeal to everybody desirous of learning what has been published on any given technical subject.

The Library of the United Engineering Society is not allowed to go into this business for the sake of making a profit; it can only do so as an accommodation to the membership of the United Societies, and the only charges made are to cover the actual expense of the service rendered. As this department has only just been formed, I have thought it might interest your readers to learn what we are doing.

E. GYBBON SPILSBURY.

New York, April 29.

Rise or Raise?

The Editor:

Sir—Noting Mr. F. Sommer Schmidt's exception to the change in his manuscript, from the word "raise" to "rise," permit me to add my protest to some of the changes from well established mining expressions and terms that are becoming more and more numerous.

For some months past, for several years I may say, changes have been suggested and in many instances made, relative to certain words, names, and expressions which have become well established by usage in the mining world, and which, as Mr. Schmidt suggests, give the impression that the writer is putting on airs. The

English language is made up of words and expressions which become correct by usage. Usage is the builder of the dictionary of any language. The lexicographer views some words through their orthographic derivation and in this narrow range of vision attempts the restriction of usage to his view-point, while in the case of other words, he unwillingly admits a correctness due to usage. How then are we to be confined to lexicographical correctness in the handling of such a word as 'raise'?

From childhood I have been accustomed to the word 'raise' as meaning an opening in a mine from a drift or tunnel upward. In mining parlance, it is as definite a term as is the word 'winze'; it is understood the world over, where English is spoken, as a distinct type of mine-opening and is as thoroughly established by usage as any other word in the language. Why then attempt, at this late date, a reversion to the orthography of the word?

Personally, there is affectation in the changing of many of the other words, so well established in mining, smelting, and metallurgy, as 'tailings,' 'smelter' (referring to the plant), and others which have been under discussion during the past two or three years. Such words have become general in their usage and familiar to all the world, as of definite meaning; they are firmly established by usage; they have, as in the use of the word 'tailings,' been applied to a definite product of a plant or to a type of plant, just as 'block' has been applied to a building in the business section of a city, or 'tree' to a type of vegetable growth. These words have not been applied from their orthographic relation, but merely suggested thereby and the 'rise' has been named a 'raise'; therefore, as it was christened a 'raise' some generations ago, let it be called a raise; let a lessee who is 'scramming' in a mine, be called a 'leaser,' as he has been by usage for years past; let the metallurgical plant, used for smelting our ores, remain a 'smelter' as it has been for some generations, and let the 'tailings' run as 'they' have since we of this generation were born.

L. S. Ropes.

Helena, Montana, April 21.

[We welcome discussion and criticism, if for no other reason but that it helps us all to understand one another. In the comments of Mr. Ropes and other worthy friends, we find great play made with the word 'usage.' Yes, we respect usage, but whose usage? Only too often the loose speech of the mining camp is quoted in support of the employment of sundry terms of an entirely local character. In many cases the vulgarisms and colloquialisms of the careless educated or reckless illiterate are called "established," while as a matter of fact they represent new variations foisted on older literary usage. What is "the mining world" to which Mr. Ropes refers? All those that are engaged in legitimate industry are worthy of honor, especially the shift-boss, but does he suggest that the trammer and timber-man are to pass on technical terminology? The 'lexicographer' or dictionary man defines words according to the usage of authoritative writers, that is, those that have a loving care for the niceties of speech and endeavor to give it maximum efficiency as a medium of thought from man to man. Is the 'lexicographer' to ask the single-handed stoper how to spell technical terms? As to 'raise' and 'rise,' we are not dogmatic. We believe the latter form preferable, and so we use it in the *Mining and Scientific Press*. It is no infliction on our readers, for even in the guise of 'rise' it will not be confused with anything but 'raise.'

We suspect Mr. Ropes of getting a 'rise' out of us, when he tilts against the up-to-date use of the singular in such terms as 'tailing' and 'slime.' This usage—that is, the recognition of a valuable inflection as distinguishing singular from plural—has been adopted widely, notably by the leading technical society in South Africa, in London also, and by many technical authorities in this country. However, we must not boast. Perhaps somebody will come to our rescue, for our sword-arm is not free in replying to this thrust of Mr. Ropes. Yes, 'block' and 'tree' are standard, but has 'tailing' any less definite meaning than 'tailings'; nay, is not 'tailing' the more definite? How would Mr. Ropes write or speak concerning the one tailing that mingled with the several other tailings? Would he speak of the 'ores' of a mine, as is often done when the mine produces only one kind of ore; if he did, how would he distinguish this case from that of a mine producing several ores, a lead ore, a zinc ore, and a gold-bearing quartz ore. If we are to say of 'tailings' that 'they' run, what is *it* that runs? Indeed, the reckless and unthinking squandering of the plural inflection is the mark of wooly thinking. In poetry we talk about the "sands' on the seashore because we are thinking of the multitudinous grains of sand; but do you mix 'sands' or 'sand' with lime to make mortar? If tailing is to be used only in the plural, why use the singular of other words and terms? We have heard miners talk of "them quarts," and we know that the immigrants to Australia expected to find gold in quarts or double pints. Are we to adopt that usage? If not, why not?

Yes, if we are to adopt localisms generally, we must employ 'leaser' instead of 'lessee,' although 'leaser' is a corruption of 'lessor,' who is on the opposite side of the fence from the 'lessee.' Certainly, we shall then use 'scramming,' 'mucking,' 'dirt,' and all the other meaningless terms adopted by men too tired to trouble about precision of speech; but if we do that, then we must allow the Australian to talk about pug, paddock, and poppet-heads; we must allow the American in Siberia to speak of starateli, hishniki, and sajenes; we must permit the Englishman in South America to write about his oficina, caliche, and barilla, and so forth *ad absurdum*.—Editor.]

The Editor:

Sir—I was much interested in the 'kick' made by Mr. F. Sommer Schmidt, published in your issue of April 17, relative to the proper term for a "shaft upside down," and it does seem too bad that many of the old names that we have been accustomed to should be

changed; and yet your evidence appears to be indisputable.

Frequently a trivial expression will lead to naming some old custom with a new appellation, and to this end I beg to state that we have for some time past been 'raising' in a 'rise,' and during that period I received a telegram from one of our interested parties asking what progress we were making in the "up-lift." Why not call it 'up-lift'; there could be no dispute as to the orthography and it would have a more soulful accent.

A. L. HORNER.

Columbia, California, April 19.

['Uplift' is good. We remember a manager in Western Australia who wrote to his board of directors in London to tell them that a winze was needed on the 4th level. They telegraphed to him to buy one right away.—EDITOR.]

The Editor:

Sir—I am 'right with' Mr. F. Sommer Schmidt in all he says in his letter of March 16, 1915. When will the editors of the Century and the Standard dictionaries learn that the function of a dictionary is to record the usage and pronunciation of words and not to force down our throats the ideas of some pedantic college professor?

If we accept the Standard as our guide to salvation, we learn that there is no such mineral as chalco'pyrite, no such place as an as'say office, and no such city as Spokane (pronounced Spo'can). Instead we have a mineral called chalcop'yrite, a place called an assay' office, and a city called Spo-cane. When will the dictionaries learn that we make as'says in an as'say office? How long! How long!

AN INNOCENT BYSTANDER.

Clarkdale, Arizona, April 20.

[Our correspondent must have misread his Standard dictionary, as that authority (1913 edition), quite correctly, gives the pronunciations chalcopy'rite and Spokane'. It is true that the pronunciation of 'assay' preferred by our correspondent is the one commonly heard; nevertheless the dictionary rendering is the time-honored and correct one, as the word is derived from the old French *assay'er*, and the old pronunciation is invariably retained for the participle assay'ing. If the word were of Anglo-Saxon origin, it would be pronounced as'say. Current usage tends to ignore the origin of the word and in a few more years may become strong enough to prevail; meanwhile those who are careful of their speech adhere to the older pronunciation. The common form, indeed, has in it a hint of the stable that is scarcely complimentary to the ass'ayer. There are many words that are commonly mispronounced, but that does not suffice to establish the faulty pronunciation as good usage. Both our correspondent and Mr. Schmidt fall into error in supposing the common form to be the older one, and the dictionary usage a new-fangled invention, whereas the reverse is the case, the old usage having been modified by accident or intention.—EDITOR.]

The Cracking of Oils

The Editor:

Sir—I note with interest the item concerning cracking of oils in 'Concentrates.' The cracking process, wherever it is in use, is intended to produce a larger yield of light distillates than can be obtained by normal distillation methods. It consists essentially in distilling oil at a temperature higher than the normal boiling-points of the constituents which it is desired to decompose and convert into products of lower boiling-point. The method is a very old one and its practical application was first carried out by having the upper part of the stills uncovered, and allowing the vapors to condense on this portion of the still and fall back into the hot still-contents. Later similar effects were brought about by distilling at high temperatures and under pressures considerably above that of the atmosphere. I suppose, first and last, anywhere from five hundred to ten thousand people have done this very thing with oils, and the result is always the same, namely, to produce a larger quantity of lighter distillate than could be obtained by distilling in the ordinary way at atmospheric pressure and without heating beyond the normal boiling-point. The various patents for methods of this character have to do with apparatus and details of operation. Everybody has the right to distill under pressure, but there are restrictions imposed upon the general public by individual patents that cover methods more or less commercially feasible. The actual decomposition is simple. For example, a hydrocarbon like $C_{23}H_{48}$, which belongs to the paraffin or marsh gas series and which is one of the constituents of ordinary solid commercial paraffin, might be broken down and a liquid obtained that would contain C_6H_{14} and $C_{17}H_{34}$. The former is a light volatile liquid of the paraffin series known as hexane and is a considerable constituent of gasoline; the latter belongs to the olefine series and would doubtless possess a bad odor and could not be used for anything except fuel. You will see that almost any kind of permutation and combination can be worked. During decomposition a fixed gas is usually evolved and carbon is left behind, as the decomposition cannot be controlled exactly. The commercial objection to these processes is that the distillate evolved usually contains olefines and similar complicated members of the aromatic and other series, which impart an undesirable color and odor to the product, so that excessive treatment is necessary to get a merchantable material. Such treatment also usually results in almost total loss of everything except the paraffin series, so that this matter of increasing the gasoline content by cracking has many sides to it, and it is usually better to adhere to the ordinary distillation methods. There are exceptions to this, as there are to all generalities.

San Francisco, May 2. E. I. DYER.

[It is a pleasant experience to have a brief item evoke so much additional information from a specialist who speaks with authority, and we wish it might become a common one.—EDITOR.]

Cost and Efficiency

By HEATH STEELE

At the beginning of this discussion on costs I want to state that at best I hope to set forth only a few of the many governing factors. The object of this article is to make a plea for a concerted effort on the part of the mining fraternity to change the almost universal method of recording costs only in dollars and cents. Such ideas as I shall present were suggested from time to time by the obvious failure of statements of cost in dollars to furnish comprehensible data for estimates. It is certain that many others have noticed the anomaly. In fact, I know that several have the same complaint to make, namely, that in using such data there is no accurate way of determining the amount of material or energy represented; hence a just comparison cannot be made. A few operators figure their costs in detail on the basis of units of energy and material, but the prevailing custom is to make a sort of financial statement of cost-data for publication, the intended usefulness of which is to promote efficiency. For several years I have had occasion to investigate mining costs and have collected a mass of figures, more or less complete, on the expense of operating the principal mines of the world. Yet I do not feel that I am acknowledging any extraordinary lack of insight when I confess that these figures are abstruse.

One object in compiling records is to furnish data for comparison with past performances at the property, as well as a record of what is being done, but the engineer or manager who stops at this point fails to take full advantage of the information before him. If he does not go farther than this he will surely fall short of attaining the highest efficiency from his labor and material. He must not only know how his present work measures up to his past achievements, but how it compares with what the other fellow is doing. And the other fellow must not be limited to his neighbors in the same district, but must include, so far as it is possible for him to learn, every form of mining throughout the world. If he does this he will set the right standard of work at his property. There should be but one standard for doing any particular kind of work, whether it is in America or Asia; depending, of course, upon the facilities at hand. Yet where is the man engaged in mining who has not known of a day's work in one mine meaning a greater or less amount of effort in another mine of the same district? For example, a driller at one is expected to drill 25 ft. per shift, while 35 ft. per shift is demanded at the other mine. Such conditions result commonly from the acceptance of a standard of work below par and are undoubtedly due to the failure properly to compare the achievements of other mining enterprises with the records there being made.

Suppose the working conditions at two mines in the same district are identical and that both are using the same system of mining and milling. We would naturally expect their costs to be the same, but suppose that the cost at one amounts to $6 per ton and $4 at the other. Now, with full knowledge of working conditions and a detailed cost-statement in dollars before us, how are we going to say which is too high? It may be that at the mine where it costs $6 the ore is more carefully selected, waste being discarded that the other is treating as ore. If this be so, the true cost at the mine reporting $4 may be $6 and the selection of ore accounts for the difference in the reported cost. But if the trouble is not in ore selection, then it must be caused by inefficient labor, loss of mechanical energy, or waste of material. We are able to discover in a comparative table of detailed costs where the difference arises, but we are not able to make a clear analysis with measurements in dollars and cents. The item of labor may be too high. How are we to know it is not caused by inefficient drilling-machines or some other such cause instead of poor workmanship? Further, if we run the trouble down to drilling-machines, again the question arises, is the trouble with the machine itself or with the drill-steel. It is certain that such questions cannot be answered off-hand from any statement of costs of the usual kind. Some information must be furnished showing the rate of drilling by the machines during actual drilling-time and the average footage per drill sharpened. If the cost of supplies is high a mere statement that it is $2 per ton will not suffice. Neither will the statement that the cost of dynamite is 25% higher at one mine than at another indicate that the difference is caused altogether by a greater consumption of explosives; one may buy its supplies more advantageously than the other. However, if the statement is before us that one mine uses 0.5 lb. of 40% dynamite per ton and the other 0.625 lb. of the same dynamite there is no question of the fact. These simple illustrations are given to emphasize the difficulty of drawing correct conclusions from general cost data, such as usually fill the engineer's note-book and the technical press, when such details are necessary before passing final judgment on records at first hand. In milling and smelter practice the custom of stating costs in units is more common, and anyone with experience knows how readily a fair comparison may be made with such statements.

Of what real use is it to know that it costs a mine in Colorado $1.50 per ton for labor and a Montana mine $3 per ton, working under the same conditions, unless supplemented with more information? On the other hand, if we know that one secures 5 tons per 8 man-hours, while the other gets only 2½ tons, the difference is explained. It is at once evident that something is wrong with the class of labor employed or with the management. The

failure to analyze records from the standpoint of the amount of human energy, mechanical power, and materials required to accomplish the different steps in mining operations has undoubtedly led to the prevailing opinion that cheap labor is always an advantage in securing a low cost, that a mine employing labor at 45c. per day has a distinct advantage over one paying $3.50 per day. As a matter of fact at many places where such low wages prevail, as in India, the tonnage per man is so low that there is a difference of about 20% in favor of the American miner at the higher wage. One fact to be borne in mind is that the amount of effective energy secured from labor varies with the intelligence of the laborer as markedly as the effective power of an engine varies according to its state of repair.

Given the rate of work to be expected from labor, the amount of power required to perform the various mechanical operations, and the consumption of supplies an engineer may apply local prices for labor and supplies and come very near making an accurate estimate of the cost of operating a new enterprise. It is hardly necessary to remark that the first factors to investigate when studying costs are the geology of the district and the nature of the country in which the deposit is situated. With the geology of the deposit must be considered the character of the orebody and methods of mining and treatment. In connection with the character of the country such factors as the climate, distance from markets, methods of transport, supply of labor, and natural resources that may be utilized for operations, must be considered. All these general factors can be ascertained in regard to the principal mining districts. Such information might be put to better use if data could readily be obtained showing the average tonnage per man, items of principal supplies expressed in quantities per ton of ore, and the horse-power required in mining and treatment per ton. With all these data and the cost-statements now obtainable, a standard of work could be computed for each group of mines working under similar conditions. It should be possible to go farther than this, to secure such details as tonnage broken per man in stopes, rate of drilling per hours of running-time, average hours of running-time for machines per shift, powder consumption, rate of timbering, rate of shoveling, and other like detailed data as easily as itemized costs expressed in dollars can now be obtained. This would certainly improve the efficiency of mining operations, for it would permit any manager to search carefully into his records to find where he falls below the other fellow. He might find differences in his cost attributed to a higher wage-scale to be partly due to inefficiency in some part of his organization.

In construction work and some branches of engineering the cost is figured by units of material, energy, etc., but mining engineers have been slow to reduce their cost-factors to this basis. One result of this is that those desiring such data are handicapped because few mines keep any complete records in these units. The accompanying form is only an outline of a summary sheet, the principles of which might be adopted by any concern. Such a summary may be compiled from more detailed information kept by each department and will show the general result at a glance. The greatest value of such a record would come through its adoption by mining companies in general and the publishing of the information in the technical press. It would require too much space to give forms that might be kept for separate operations, or to try to cover all items, but it might be well to mention a few of the subjects that should be covered. While the general departments such as offices, mechanical, electrical, etc., are finally absorbed in the cost of running the main operations, some information should be at hand to compare their efficiency with those of other companies. Careful consideration should be given to the number of men necessary to run these departments for a mine of given size. The consumption of supplies for their maintenance and machinery efficiency are equally important. A record should be kept of the total shop-hours operated, details of labor employed by occupation, average man-hours per shop-hour, average cost of supplies for maintenance per shop-hour and man-hour. Some of the following facts are important to ascertain about mining operations:

Tons per day per man employed on surface.

Tons per day per man employed underground.

Tons per day per man for all men employed at the mine.

Tons broken per day per man employed in stopes.

Tons produced per day per man employed in development.

Tons produced per day per man employed in general underground work.

Feet of development work per day per man on development.

Foot-tons trammed per day per man from development headings.

Foot-tons trammed per day per man from stopes.

Feet drilled per machine-shift in stopes.

Feet drilled per machine-shift in development.

Drills sharpened per foot drilled by machines.

Actual drilling-time in stopes.

Actual drilling-time in development.

Tons broken per machine-shift in stopes.

Feet advanced per machine-shift in development.

Total air-consumption for drilling per ton of ore produced.

Tons secured from stopes per cubic foot of free air in drilling.

Feet advanced in development per cubic foot of free air in drilling.

Tons broken in stopes per foot of hole drilled.

Feet advanced in development per foot of hole drilled.

Average consumption of drill-steel per ton of ore produced.

Average amount of drill-steel sharpened per man-hour.

Pounds of powder consumed per ton of rock broken in stopes.

Pounds of powder consumed per cubic foot of development.

Timber consumption in stopes per ton of ore.

Timber consumption per foot of development.

Total timber consumption per ton of ore produced by mine.

Average amount of track, spikes, rails, etc., consumed per ton of ore produced.

Average pipe-consumption per ton of ore produced.

Lubricating oils and greases consumed per ton of ore produced.

Average hoisting depth or total foot-tons hoisted.

Average power consumed per ton or foot-ton hoisted.

Details of power-consumption in operation, such as pumping, etc.

Total power-consumption at mine per ton of ore produced in horse-power-hours.

Milling data should be collected to show the power, labor, and supplies required for the various steps in the course of treatment as expressed in units. For example, the amount of power required to crush a ton of ore from one size to another and downward through concentration to the final product. Data published on the efficiency of machines are usually compiled in units of power, but if the practice of giving out this information was more widespread it would be better. It is necessary to face the fact that while a dollar is a known quantity in the monetary system, it is by no means a definite expression when used to denote quantities of labor and material, and that so long as operators continue to use it to measure labor, supplies, and power in mining they will fail to raise mining operations to the highest standard of efficiency.

By these remarks I have not intended to convey the impression that I advocate the introduction of such data into the general accounting or cost-record system of mining companies, or that all these facts should be published in their annual reports. But I do advocate that operating departments should keep some such records and that the heads of these departments should make a careful study of their costs on this basis. To further the cause of efficiency they should, if possible, publish such information in the mining journals, so that general comparisons may be made between mines.

GENERAL SUMMARY OF COST & EFFICIENCY DATA FOR ALL OPERATIONS

		Departments	Mines	Trans-portation	Milling	Smelting	Selling	Construct-ion	Total
	Tons Handled								
LABOR	Total Labor Cost								
	Total Man Shifts								
	Av'g Wage per Man Shift								
	Tons Handled per Man-Shift								
	Cost Labor per Ton Handled								
SUP-PLIES	Total Cost Supplies								
	Av'g Cost per Man-Shift								
	Cost Supplies per Ton Handled								
MISCL. CHGS.	Total Cost Miscellanies								
	Av'g. Cost per Man-Shift								
	Cost per Ton Handled								
POWER	Total Cost of Power								
	Total H.P.-Hours								
	Av'g. Cost per H.P.-Hr.								
	Tons Handled per H.P.-Hr.								
	Cost Power per Ton Handled								
	Total								
	Distribution of Department Charges								
	Total Cost of Operations								
	Total Cost per ton Handled								
	Net Metal Production.								
	Total Cost Per Unit of Metal								
	Per Balance Sheet	No.	No.	No.	No.	No.	No.	No.	No.

Average cost of keeping mine-tracks in repair per mile of track, labor in man-hours.

Ton-miles hauled by underground locomotives.

Details of power-consumption for underground haulage in horse-power-hours, per ton-mile.

Ratio of supply-cost to labor-cost.

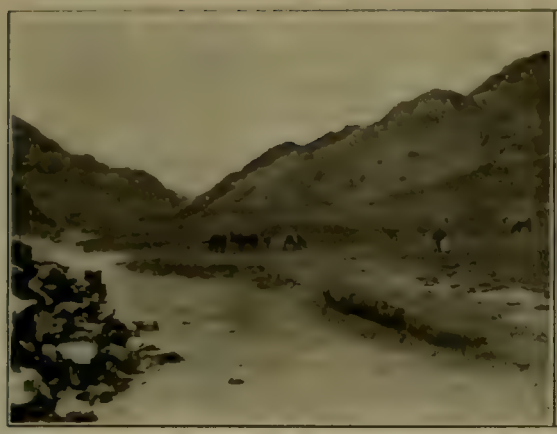
Ratio of cost of separate operations to total cost.

Many of these and other facts may be obtained from the regular system of reports now in use. When publishing such information it is important to know the hours represented by a shift, the amount of ore and waste actually broken, the amount of ore and waste hoisted, proportions of rock hoisted as ore that is later discarded as waste in sorting, ratio of development work to ore produced, average grade of underground tracks, etc. It is also interesting to collect these details to show the relative merits of the different systems of mining employed, and to show development data for driving, shaft-sinking, rising, and sinking winzes, in fact, any segregation of costs that will throw any light on the performance of work under different conditions about the mine.

GOLD AND SILVER MOVEMENTS in New York up to March 27 were as follows:

	Exports.	Imports.	Same period of 1914.	
Gold	$2,493,700	$6,255,809	$18,335,854	$3,008,936
Silver	9,347,185	1,401,203	9,769,732	2,793,657

Added to the imports of the current year is the sum of $30,500,000 received from the Bank of England's auxiliary reserve at Ottawa, Canada, to which over $100,000,000 was sent from New York last year. Nearly 50% of the gold exported between August 1 and December 31, 1914, has been returned to this country.



1. THE PASS.

2. CALUYO STAGE-STATION.

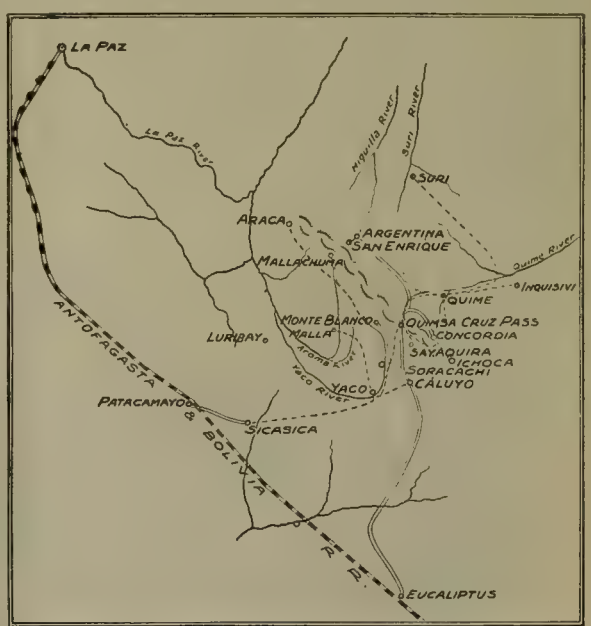
Quimsa Cruz Tin District, Bolivia

By FRANCIS CHURCH LINCOLN

The tin deposits of Bolivia extend from Carabuco, on Lake Titicaca, near the Peruvian border, southeast for some 400 miles along the main range of the Andes to Portugalete, near the Argentine boundary. The northernmost producing district is that of Milluni, in the department of La Paz, north of the city of that name, which has been described in a previous article.* The next in order is that of Quimsa Cruz, in the same department, but southeast of the city of La Paz, about midway between it and Oruro, as may be seen by reference to the sketch-map.

The Quimsa Cruz district stretches from the town of Araca, and for about 35 miles to the town of Ichoca. Quimsa Cruz means 'Three Crosses' in Aymará Indian, the name having first been applied to the principal pass, and later to the district as a whole. The pass has an altitude of 15,570 ft. above the sea and derived its name from three piles of stones, locally termed 'crosses,' which mark the trails to Caluyo, Yaco, and Quime, respectively. The Indians believe that the high passes of the Andes are inhabited by genies, who can be placated by the throwing of a stone upon a pile by the roadside. This will bring good luck. The designation of the piles as crosses indicates an attempt on the part of the missionaries to Christianize a heathen superstition.

This district lies northeast of the Antofagasta-Bolivia railway, which runs from La Paz to Oruro, and thence to the Chilean coast at Antofagasta. Most of the tin ore and concentrate produced in the district is packed on llamas, burros, or mules to the railway at Eucaliptus or Patacamayo, while a little is transported as far as La Paz and Oruro. A regular weekly stage-coach runs from Eucaliptus to Caluyo, 42 miles from the railroad, beyond which the road branches to the Monte Blanco, Huanchaca, and Concordia mines. The Caluyo stage-station is shown in the accompanying photograph. Mail for the district comes from La Paz weekly by rail to Patacamayo and thence by carrier *via* Sicasica. There



MAP OF THE REGION.

are Government-telegraph stations at Caluyo, the towns of Yaco and Quime, and the mines of Monte Blanco, Concordia, and Pacuni.

The country-rocks of the tin lodes are slate and quartzite intruded by a granitic batholith and acidic dikes.

Mining and Scientific Press, March 27, 1915.

At the Concordia mine, and probably elsewhere in the district, the sedimentary rocks are of Devonian age. Outside the lode-area, as at Yaco, where tin placers are worked, the slate and quartzite are overlain unconformably by red desert sandstones of Triassic age. The granitic intrusion appears to be quartz-monzonite, while the dikes are quartz-porphyries. The quartz-monzonite makes its most southern appearance at the Argentina mine, 15 miles north of Quimsa Cruz pass, the outcrop being said to extend north for 10 miles to Araca. Several quartz-porphyry dikes were observed south of Quimsa Cruz pass. The tin lodes appear to be genetically related to these igneous rocks. The topography of the district is glacial, and small glaciers still exist on the higher peaks.

The lode deposits are all veins, but so greatly do their characteristics vary that no general description will suffice. The valuable mineral is cassiterite, which is usually purer and richer closest to the surface and at the highest altitude. This condition may be explained, in part at least, by secondary sulphide enrichment, which is apt to proceed deeper in higher altitudes because the ground-water level is lower. The leaching of the upper parts of the lodes increases the purity of the ore and renders it richer per ton if not per cubic foot, while the precipitation of sulphides in the lower parts of the lode has exactly the reverse effect.

The Argentina and San Enrique mines adjoin one another in the quartz-monzonite area. Sugar-Loaf peak, at the Argentina mine, is shown in the accompanying photograph; also the San Enrique mine. The igneous rock at these mines is sheeted almost perpendicularly, as may be seen by examining the photographs, the direction of this sheeting varying from N.75°E. at the Argentina to N.17°W. at the San Enrique. The veins are numerous and strike in all directions, frequently branching and occasionally crossing one another. They appear to have been formed contemporaneously. At the Argentina they are somewhat narrower and richer than at the San Enrique. The typical ore consists almost entirely of a gangue-mineral believed to be tourmaline, and the ore-mineral cassiterite. The tourmaline occurs in radiating groups of dark-green acicular crystals, ⅛ to ½ inch in diameter, the interspaces being filled with brown cassiterite.

Across the range, just outside the quartz-monzonite area, is the Mallachuma mine. The workings at this mine extend beneath a glacier. The veins are in quartzite, but the glacier brings down boulders of quartz-monzonite, showing that the outcrop of the igneous rock is not far distant. The veins are nearly parallel, but they branch and unite, forming a linked system with a strike ranging from N.10°E. to N.80°E., and nearly perpendicular dips. This linked-vein system cuts across the quartzite, which is thickly bedded and dips from 29° to 35° in a direction varying from S. to S.15°E. As at the Argentina and San Enrique mines, the veins at Mallachuma all seem to have been formed at the same time. The filling consists of quartzite, quartz, pyrrhotite, arsenopyrite, pyrite, cassiterite, and a little hematite, chalcopyrite, and tourmaline. Traces of lead, antimony, zinc, and silver are also shown by assay. The proportion of the various vein-minerals varies widely, not only in different veins but also in different parts of the same vein.

There is one American mine in the Quimsa Cruz district, the Concordia mine of the Andes Tin Company. This vein is also in quartzite, but, unlike the Mallachuma veins, it has a brecciated filling and has in places been intruded by a dike of quartz-porphyry. The strike of the Concordia vein is N.10°E. and its dip nearly perpendicular. It has been faulted in numerous places, the northern segments always having moved toward the east. The filling consists of brecciated pieces of quartzite, tongues of quartz-porphyry, quartz, tourmaline, feldspar, muscovite, sphalerite, pyrite, and cassiterite. The geology of the Concordia lode has been described in detail by William R. Rumbold,† who has also described briefly the geology of the Coya, Monte Blanco, Barrosa Cota, and San Roque mines in the Quimsa Cruz district. Besides the American mine, there is also an American prospect in the Quimsa Cruz district, namely, the Scranton of B. Sandall & Co.

Stream-tin derived from the Quimsa Cruz lodes is found in the Yaco and Aroma rivers. It occurs on and near bedrock in both the river and bench-gravels. The river-gravel is 5 to 12 ft. thick and consists of equal amounts of sand and small boulders; while the bench-gravel is 5 to 30 ft. thick and contains a larger proportion of sand, together with soil and clay, not present in the river-gravel. The stream-tin varies in size from powder to boulders a foot in diameter. Its metallic content is low; shipments of first-class ore ranging from 52.67 to 58.45% metallic tin, but it is much less complex than the lode-ore, the principal impurity being quartz. Besides the first-class ore, which makes up about 85% of the product, there is 15% of second-class ore of lower tin content and containing pyrite. Gold has also been found in the Yaco river, nuggets weighing several ounces being not uncommon and one weighing 51 oz. having been discovered, but it is very irregularly distributed and of little commercial importance. On the Yaco river, the quantity of stream-tin per square yard of bedrock increases toward the lode mines, but suddenly decreases before they are reached. This suggests that a glacier was active in bringing the stream-tin down to the point where the sudden increase begins, the small amount of stream-tin above this having been brought down during or after the retreat of the glacier.

Tin was discovered in the Yaco river in 1903 and about 4 long tons of first-class ore has been produced from the Yaco and Aroma rivers since then. Most of this has been mined by tributers. These miners dig small pits in the river-gravel to bedrock, work out as much ground as they can reach from the bottom before the pit caves, and then start a new one. The tributer must dispose of his product to the owner of the placer.

†*Economic Geology*, Vol. IV, p. 321 (1909).

who pays him a certain pre-arranged rate per 100 lb. (quintal), which varies with the price of tin. In 1914 this ranged from $6.40 to $8 (16 to 20 bolivianos). J. A. Sedlmayr, manager for the Nuevo Jerusalem placer, employed miners by the day to dig trenches as shown in the photograph. These men were paid 40c. per day and given a bonus of $\frac{1}{10}$c. per pound on all the stream-tin they extracted.

The wages paid at Yaco are the lowest in the district, because labor is plentiful, the cost of living low, and the climate good. At the lode mines it is wet and cold, living is dear, and labor comparatively scarce. Labor is frequently supplied by contract, the contractor being paid 40c. for each Indian. Sometimes a bonus of 20c. is paid for such Indians as stay a second month, and an additional bonus of 10c. for those who stay a third. The wages paid are about as follows:

Outside men	$0.80
Shovelers	1.20
Trammers	1.40
Miners	1.60
Blacksmiths	2.00

About three-quarters of the wages earned is usually spent in the company stores, where profits ranging from one-sixth to one-eighth are realized, thus reducing the actual cost of labor by one-eighth to one-quarter.

Mining supplies cost about as follows:

Dynamite	$0.40 per lb.
Caps	0.88 per 100
Fuse	0.10 per 20 ft.
Charcoal	1.40 per 100 lb.
Blacksmith coal	4.80 per 100 lb.
Wood	0.60 per 100 lb.
Drill steel	0.16 per lb.
Hammers	0.20 per lb.

Figures as to the cost of mining are difficult to obtain, as detailed accounts are seldom kept. The following detailed costs of mining 811 tons from a narrow vein with 9 men stoping will therefore be of interest:

Labor:	Per ton.
Miners	$1.980
Blacksmith and helper	0.096
Nipper	0.060
Trammers	0.232
Sledging in stopes	0.092
Loading and firing shots	0.056
Sampling	0.008
	$2.524
Supplies	0.804
Supervision	0.500
Overhead charges	1.544
Total	$5.372

Mining the same type of vein on a large scale would greatly reduce the cost of supervision and the overhead charges, bringing the total down to about $4.50; while in wider veins this would be further reduced to about $3. The cost of development work on the same property, exclusive of superintendence and overhead charges, was about $10 per foot for 5 by 7-ft. adits, cross-cuts, rises, and winzes; and $8 per foot for intermediate drifts averaging 3½ by 4½ ft. The list on the next page shows the producing mines in the Quimsa Cruz district in the spring of 1914.

The methods of milling employed in the district range from the crudest to the most refined. Primitive methods are in use at the small mines. At the Argentina mine, crushing is performed by rocking great stones, known as *quimbaletes,* back and forth over the ore. The crushed ore thus obtained is screened by hand and concentrated on convex buddles.

The mill at the San Enrique mine is a complex form of the primitive type. Instead of using *quimbaletes,* a Chilean mill having a single granite roller, chipped by hand out of the solid rock, is employed. Power for this

mill is supplied by a small impulse water-wheel. Concentration is effected by hand-screens, hand-jigs, circular convex buddles, oblong moss-bottomed buddles, and barrels fitted with paddles. These machines are used and re-used, according to a complicated system that produces concentrate ranging from 58 to 62.3% metallic tin. The loss by this system is high, probably exceeding 30%.

Modern mills have been erected at the Viloco, Monte Blanco, Huanchaca, and Concordia mines. The cost of milling at these plants is about $1 per ton. The loss is said to range from 5 to 25%, and probably usually exceeds 10%.

I took 29 samples from four properties in the Quimsa Cruz district. The assays ranged from 0.41 to 10.81% metallic tin, and averaged 4.83%. With a milling loss slightly in excess of 10%, such ore would concentrate 15 into 1, yielding 65% tin concentrate. With a cost of $4 per long ton for mining and milling, the cost of producing one long ton of 65% concentrate would be $60. Transport to the railroad would cost about $30; while exporting, shipment to Europe, and smelting would cost about $200; thus bringing the total cost up to $290. The value of the tin in 65% concentrate, when the price of Straits tin in London is £185, would be $585. Deducting $290 from this would leave $295 as the profit per long ton of concentrate, equivalent to nearly $20 per ton of original ore.

WITH THE PAYMENT of its posted dividend of 65c. per share on March 25 the total dividend disbursements by the Homestake Mining Co., of South Dakota, will reach a total unsurpassed by any gold mine in the western hemisphere, namely, nearly $37,000,000.

MINERAL PRODUCTION of Rhodesia in 1914 was as follows:

	1914.	1913.
Gold	£3,580,209	£2,903,268
Silver	14,275	15,105
Lead	2,487	5,234
Chrome iron	107,612	141,481
Tungsten ore	.....	427
Asbestos	8,612	5,224
Coal	115,099	78,421
Copper	50,559	.....
Arsenic	161	.....
Diamonds	3,985	7,781
Total	£3,882,999	£3,156,941

The increased gold production of £676,941 is principally due to new producers, namely, the Bell, which entered the producing list in March (£60,410), Falcon in August (£50,416, apart from copper), Cam & Motor in January (£171,602), Eileen Alannah in the same month (£46,864), Shamva in February (£272,871), and Golden Kopje in September (£28,274), while the Kimberley, which came into the list late in 1913, increased its output from £30,000 to £75,000, and the Antelope similarly from £4600 to £94,300. The decreases that may be expected in the future will doubtless be more than counterbalanced by the yields of the new producers. Nor must the part, large and important in the aggregate, played by the small producers be overlooked.—*South African Mining Journal.*

GOLD YIELD of the Lena property, Siberia, from September 30, 1914, to January 10, 1915, amounted to 61,130 oz. from washing 121,895 cu. yd. Gravel mined totaled 255,122 cubic yards.

Quantitative Blowpipe Analysis in the Field

By GEORGE DELIUS

For the benefit of those interested in making blowpipe assays during field-work I shall give a few hints by which the work may be much simplified. During a period of over 20 years of experience with this method, I have found that blowpipe analysis gives accurate quantitative results, as proved by check assays. Accurate results are certain, in a fraction of the time required by the usual fire-assay, providing the operation is conducted in the proper manner. The apparatus can be purchased from any reliable dealer in assayer's supplies; but I have found some of the usually advertised parts to be not quite suitable for practical work, especially for the field. The whole apparatus should be of the simplest, yet at the same time of the most practical, construction possible. A stout satchel which opens at the top, with strong straps and handles convenient to transport on pack-animals if necessary, is used for carrying the outfit. Bottles with acids should be separately packed, to guard against injury in case of breakage. A small folding table is desirable, but not essential. Any place sheltered from the wind will do to set up the apparatus to perform efficient work. As fuel for the blowpipe lamp, I have found common kerosene to be the most satisfactory. An efficient blowpipe lamp is readily constructed by fitting a common large-necked bottle, about 6 inches high and having a metal screw-cap, with a large-sized lamp-burner with a flat wick. By removing the superstructure of the burner, soldering it to the screw-cap, and filing the upper flat part to an angle of about 35°, a most efficient blowpipe lamp is produced. A flame over 5 inches long can be obtained by using this lamp and kerosene. It is easily regulated and the flame answers for both reduction and oxidizing purposes. If turned down until smokeless, the lamp can be used for gentle heating for such purposes as parting.

I will briefly describe in detail the different parts of the outfit, and their proper uses. A small bell-shaped mortar, about 5 in. across the bell, is most satisfactory for the fine crushing of ore samples. I generally crush to about 20 mesh, after having quartered down in the usual manner. The 20-mesh pulp is quartered to about 1 oz. This quantity can be quickly reduced to 150 mesh or finer in the mortar. It is, of course, of prime importance to sample correctly, and nothing coarser than 150 mesh should be used to obtain the final sample. The fine pulp is now ready to be mixed on a sheet of black glazed sampling-paper. It should be spread evenly in a thin sheet. From this sheet of fine pulp, with the aid of a small and thin spatula, small quantities are taken from as many equally spaced places as convenient, and one or more blowpipe assay-tons (100 mg. in weight each) weighed out accurately. The weight of one blowpipe assay-ton being 100 mg., a button of silver obtained by the assay weighing 1 mg. represents exactly 1% in weight of the one assay-ton of pulp taken for assay.

I have found the common pulp-scale unhandy under some field conditions, and furthermore not quite delicate enough, but have managed to devise a more accurate pulp-balance for this purpose. It is constructed on the balanced single-lever principle, shows quick-weighing qualities, easily weighs down to 0.1 mg., and when dismantled occupies a very small space. The small scale-pan can be lifted off the balance, after weighing the pulp, and is of the proper shape to pour its contents directly into the small mixing scoop, in which the pulp is thoroughly mixed with proper fluxes, such as borax glass, sodium bicarbonate, silica, and test lead. The weights used for this pulp-balance are in the form of small riders made of aluminum, different sizes representing blowpipe assay-tons or fractions thereof. By using standardized regular assay-balance weights as counterweights, these riders are constructed without difficulty. A set of regular assay-weights from 1 gram to 0.1 mg. should be carried, to construct new weights at any time or check up old ones.

Suppose now sampling has been attended to, the exact assay-ton (100 mg.) weighed out, the fluxes in proper proportion mixed with the pulp in the mixing scoop, the charge is next transferred to a small soda-paper cornet and folded up into a little ball about ⅜-in. diameter. These cornets are made from a good grade of filter paper, previously saturated with sodium bicarbonate, and dried. The paper capsules are very simply made by cutting the impregnated filter-paper into rectangular pieces 1½ by ¾ in. and by rolling the little paper squares around a smooth wooden mandrel (made from a lead-pencil), making a paper tube about ⅜ by ⅝ in. long. They are each tightly folded over on the end of the mandrel, and slipped off ready for use. The charge is readily poured into the tube by the aid of a fine camel's-hair brush without any loss. The open end is then folded over tightly and it is ready for the furnace. The furnace in this case is a stick of charcoal with a crucible-shaped hole bored in either end. The quality of charcoal for this work is of prime importance. I have found that common pine or fir charcoal, if properly burned, answers the purpose admirably, and I recommend its use in preference to willow charcoal. The stick should be about 5 or 6 in. long, and the holes bored, with a proper charcoal-borer, to a depth of ½ in. by approximately ½-in. diameter at the open end and smaller at the bottom. The holes must be bored at the grain ends of the charcoal in every case.

A gentle oxidizing flame is now directed upon the

folded paper surface of the charge in order to burn off the surplus paper. After the contents of the crucible are in a fluid state, the reducing flame reduces all the test lead, which, if properly done, collects the metal contents of the assay into one button, attached and partly surrounded by the fluid slag. The heat is now increased, using the reducing flame only. When finished the charge is ready to be poured. I use for this purpose a small, smooth, cup-shaped piece of Acheson graphite, as neither the slag nor lead button will adhere to this. While the pour is still red-hot in the graphite cup a drop of water will, if properly handled, form a balloon-shaped bubble of cold slag. This gives a valuable clue to the content of the gangue rock by the color imparted to the slag.

The lead button should be bright and soft; if otherwise, it shows the presence of sulphur, arsenic, or antimony. If bright but very hard, it indicates a high silver or gold content. The operation having proceeded so far, the lead button is now ready for cupellation. If the button is not perfect, it can be readily purified by replacing in the same crucible and scorifying it until pure. If this is not done the impure lead button will present difficulties in the subsequent cupellation for fine metal. The cupels for blowpipe use must be made of not less than 60-mesh bone-ash, of the best quality. They must present a smooth inner surface, and in spite of fine grain must show no tendency to form cracks, for the minute spherical silver or gold buttons resulting from low-grade ores might be lost into the cracks. Besides, if the button comes to final rest directly over a crack, its perfect spherical form, which any blowpipe button should assume on solidification, would be destroyed.

The cupellation of the lead button, which now contains all the silver or gold originally in the pulp taken for assay, is next. The lead button is cleaned from any adherent slag and placed on the smooth cupel, after heating the cupel to a low red heat by the blowpipe. The cupel itself is readily made by using the metal cap of a No. 10 paper shot-gun cartridge for a receptacle for the fine bone-ash, which must be dry and powdery. The little brass cap is filled tightly with bone-ash, and the surface made perfectly smooth by the aid of a smooth pestle, shaped according to the curved surface to be desired. I have found nothing better for this purpose than a common glass or agate marble about 1½-in. diameter. This gives just about the right curvature to the cupel surface, and also the smoothness necessary. The lead button is placed near the rim of the hot cupel and a small oxidizing blowpipe flame is directed on the lead button. A gentle heat will cause the lead to 'open' and commence to scorify. The oxidizing red-hot lead should be surrounded by a partly melted bath of litharge. When the lead button becomes about the size of a large mustard-seed, it is allowed to roll upon the clean, hot cupel surface; it is kept rolling about until the sudden brightening of the resulting silver or gold-silver bead shows that the operation is finished, the lead having been completely removed.

The silver, or silver-gold, button thus produced is now ready for weighing. The small button is a perfect sphere, with a minute flat spot where it came to rest on the smooth cupel, and is, for blowpipe work, not generally weighed on an assayer's balance, but measured on a Plattner ivory scale. The principle of the scale is based on the fact that the diameter of a sphere of any given metal is exactly proportional to its weight. The ivory scale is constructed of a thin polished strip of pure white ivory, about 7 in. long by ⅛ in. wide. On this smooth surface two converging hair lines are drawn with a diamond point. These two fine lines come together at one end, and diverge at the other end a distance of less than one millimetre. The whole length of these converging hair lines is divided exactly by 50 cross-lines, with subdivisions representing, for silver, weights from 0.00002% at the lower end to 3.48% at the upper end for each 100 mg. in weight taken for the assay.

The accuracy of the ivory scale is proved by taking a series of five or six silver buttons of different weights, ranging from 3 mg. to ½ mg., weighed with extreme accuracy on a good assayer's button-balance. Re-treat each button, after ascertaining its exact weight, on a fine blowpipe cupel with a minimum of pure test lead. Then measure the buttons on the Plattner ivory scale. If the scale is properly constructed, each little button will correspond to the weights previously determined by the button-balance. If variation exists, the ivory scale is imperfect, not having been properly calibrated.

When cold the bead is lifted off the cupel and is ready for weighing. It is removed from the cupel with a fine pair of jeweler's tweezers and transferred carefully to the Plattner ivory scale. With a good magnifying glass its exact position between the two hair lines can be determined quickly. The true place being found, the corresponding number on the scale at once shows its exact weight. Suppose the little spherical bead fits exactly between the hair lines on the ivory scale at the place numbered 33; its weight, if pure silver, is exactly 1% of the charge of 100 mg. taken. This corresponds to 291.66 oz. per ton of 2000 lb. If the silver button contains gold, it is parted with a drop of parting acid, washed, and the gold taken up with a tiny piece of pure leadfoil, held by the tweezers. This is replaced on the cupel, re-cupelled, and the weight of the pure gold deducted from that of the silver.

A little practice will soon make the operator sure of all operations in handling small quantities of pulp. For convenience, and in order to save time, I have calculated the results in weights corresponding to the numbers on the Plattner ivory scale and plotted them in the form of a simple table which is a great convenience, especially in the field. The operations of quantitative blowpipe analysis are simple, although requiring patience and practice in order to become sure of results. I hope this synopsis will contribute to a better understanding of it.

Labor-Saving Devices

By S. A. WORCESTER

The adoption of minor conveniences that operate automatically is often the means of saving the labor of one or more men, in milling plants. It is an established fact that for the majority of simple mechanical operations, machines are more reliable than manual labor, so that a mill designed to be automatic is less liable to interrupted operation than one having few automatic features and requiring careful attendance at many points.

The devices shown, while not claimed as original, are much needed, as I know from extended observation, in a large number of mills, where they would prevent many sloppy overflows and kindred troubles, saving labor in some cases and power in others.

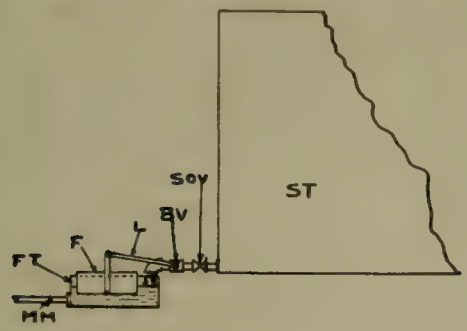

FIG. 1.

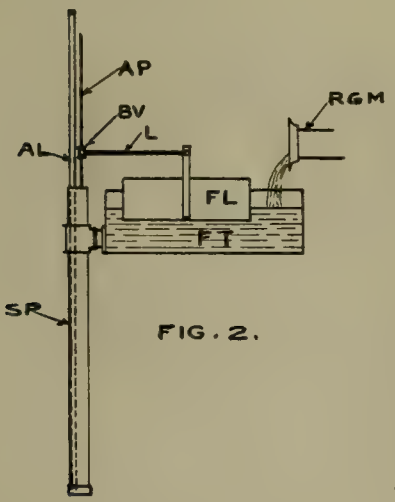

FIG. 2.

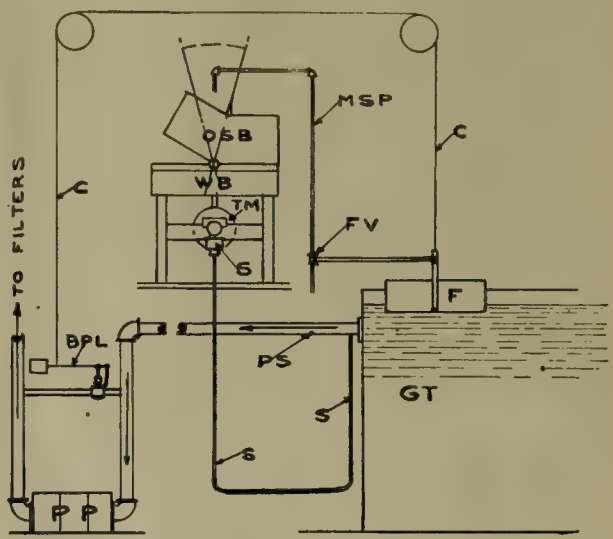

FIG. 3.

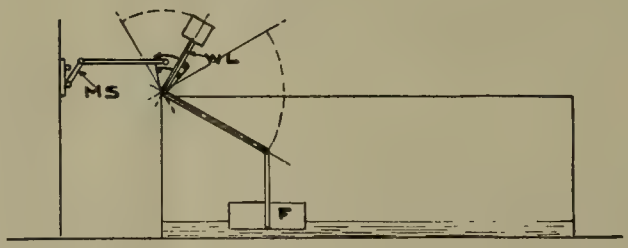

FIG. 4.

Mill-Pressure Regulator

Where a uniform head is needed for supplying water or solution to classifiers or concentrators, the float arrangement shown in Fig. 1 is satisfactory. Receiving water or solution either from a storage-tank, as shown, in which the level of the fluid varies from near the top to near the bottom, or in other cases receiving from a main in which the pressure fluctuates, the float-tank *FT* has its liquid-level maintained within a narrow limit of variation and allows the pressure in the mill-main *MM* to fluctuate but slightly, not more than a few ounces, whatever the mill-demand or the supply-variation may be. The float *F*, connected by the lever *L* to the butterfly-valve *BV*, governs the supply to the float-tank. A lever-gate or almost any form of lever-valve may be used, but I prefer the butterfly-valve as the easiest to operate. It is desirable in most cases to have a shut-off valve *SOV*, in addition to the regulating valve, for use in case of shut-downs, because a lever-valve, particularly the butterfly, seldom closes tight. The float shown is a light steel pan or bucket, but a cheap float can be made of wooden blocks nailed together, or a single large block.

The lever-valve should be large enough to give an opening equal to the full pipe without opening wide. It will then regulate the flow with slight movement of the float.

Air-Lift Regulator

Air-lifts for raising pulp from the discharge ends of tube-mills and other re-grinding machines are usually run with considerable waste of air. This regulator, Fig. 2, effects a considerable saving. The float *FL*, connected by the lever *L* to the butterfly-valve *BV*, governs the quantity of compressed air admitted through the air-pipe *AP* to the lift *AL* in the submergence pipe *SP*. Any increase in pulp-supply from the re-grinding machine *RGM* raises the float and admits more air to the lift, while a decrease in pulp reduces the air supplied. The float-tank is made small, so that the pulp will keep in motion and not accumulate enough to impede the movement of the float.

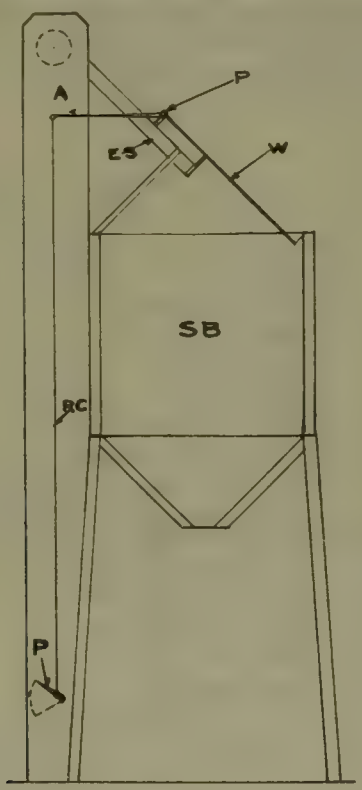

FIG. 5.

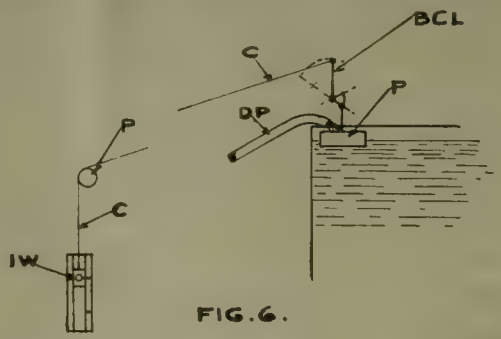

FIG. 6.

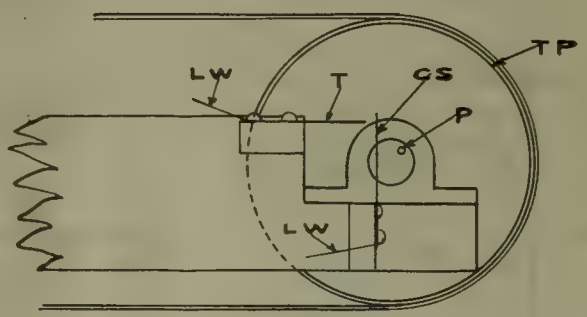

FIG. 7.

Zinc-Dust Feed-Regulator

This arrangement, Fig. 3, governs the quantity of solution delivered by the precipitation-pump *PP* to the filter-presses, and at the same time proportions the amount of zinc-dust fed to the pump-suction *PS*, to the volume of pregnant solution drawn from the gold-vat *GT*. The gold-solution level is thus kept within a narrow range while the influx may vary widely. The float *F* is connected by the cord *C* to the by-pass valve-lever *BPL*. The pump has constant speed and delivery, but when it reduces the level of the gold solution sensibly the float is lowered, opening the by-pass and reducing the volume pumped to the filters. Increased inflow to the gold-vat raises the float, closing the by-pass and increasing the quantity pumped to the filters. Zinc-dust is supplied to the pump-suction by a feeder operated by the oscillating solution box *OSB*, the frequency of oscillations and proportionate feed depending on the quantity of mill-solution supplied to the oscillator through the float-valve *FV* and pipe *MSP*. The float thus governs both pump and feeder. The oscillating box rotates, by means of a ratchet, a small screw-conveyor in the bottom of the zinc-dust hopper, feeding the dust out into the water-box *WB*, from which the solution discharged from the oscillator washes it out into the tube-mill *TM*. Here it is thoroughly emulsified and discharged into the open end of the siphon *S*, through which it enters the suction *PS*. It is obvious that by using a long or short lever for the float, the range of the solution level may

be varied from a few inches to several feet, as may be required under the conditions prevailing in the plant.

Automatic Pump-Control

Fig. 4 shows a simple device for such applications as, for instance, returning barren solution from sump to stock-vat, etc. An individual motor driving the pump is started and stopped by the switch *MS*. The float *F* can rise until the vat is nearly full, or lower until it is nearly empty, before forcing the weight-lever *WL* to one side or the other of the perpendicular, so that it falls, throwing the switch and starting or stopping the motor. This prevents the tank from overflowing, and avoids wasting current by running the pump after the tank is empty.

Storage-Bin Indicator

Fig. 5 shows a tell-tale for indicating when an elevated bin for crushed material is full, without the necessity of climbing to the top of the structure. The wing, or paddle, *W* is so hung and pivoted at *P* on the elevator-spout ES, over the storage-bin *SB*, that as the crushed material delivered by the elevator rises above the bin, it swings the wing *W* outward and upward. The arm *A*, attached to the wing, is connected by the rod or cord *RC* to the pointer P, placed near the ground-floor. When the wing rises this pointer swings down, showing to the operator that the bin is full.

Pump-Discharge Indicator

Fig. 6 shows a device to indicate whether a pump is discharging to full or part capacity. When the pump is on the lowest floor and the discharge is on the highest, several floors above, and at a considerable distance, this device saves time, labor, and trouble. The shallow pan *P*, hanging under the pump-discharge pipe *DP*, has a bottom outlet that is adjustable by a slide or damper. The pan hangs on the bell-crank lever *BCL*, which has attached to it a light cord *C*, passing over the pulley *P* to the indicator-weight *IW*. This indicator is placed at some convenient point in full view of the operator. The pan outlet is so adjusted by experiment that when the stream entering the pan is less than the full pump-capacity, the pan will but partly fill and the weight will partly overbalance it and descend a part of its stroke. When the discharge stops, the pan soon empties and the weight descends to the bottom of its travel, showing that the pump has stopped.

Electric-Conveyor Tell-tale

Fig. 7 shows an electric appliance to indicate the continued running or the stoppage of a tailing or other conveyor that may be placed at a long distance, or out of sight, from the mill. The pin *P*, in the end of the shaft of the tail-pulley *TP*, presses the contact-spring *CS* against the terminal piece *T*, at each rotation of the tail-pulley, making connection between the light wires *LW*, so as to flash a light at a convenient place in the mill at each turn of the pulley. If the light stops flashing, it gives warning of stoppage of the conveyor.

Metal Production of Japan in 1914

The yield of the principal mines was as follows:

Gold. Hidachi, $1,803,873; Sado, $367,167; Yamagano, $281,113; Kushikino, $238,605; Kosaka, $225,452; Kamaishi, $146,518; Tomiki, $105,902; Serigano, $83,803; Abeshiro, $81,087; Okayabu, $70,178; Nishinomiya, $67,680; Matsuoke, $66,145; Omori, $61,220; Okuchi, $56,387; Miyagi, $55,213; Ushio, $51,368; Horobetsu, $50,355; Ikuno, $50,290; and 37 other mines producing less than $50,000 each, $547,795; making a total of $4,476,500.

Silver. Kosaka, 956,885 oz.; Hidachi, 802,700; Tsubaki (closed in September), 460,668; Ashio, 320,035; Kamioka, 283,620; Ikuno, 221,968; Abeshiro, 232,914; Sado, 166,257; Kushikino, 126,084; Omodani, 119,838; Omori, 119,140; Takonai, 85,124; Kunitomi, 66,492; Yoshioka, 64,944; Ani, 60,969; and 45 other mines producing less than 60,000 oz. each, 578,061; making a total of 4,647,767 ounces.

Copper. Ashio, 24,025,589 lb.; Hidachi, 22,897,819; Kosaka, 16,991,684; Betshi, 16,829,118; Asarusawa, 4,717,545; Ikuno, 4,516,380; Abeshiro, 3,911,130; Agoya, 3,348,869; Ani, 3,103,557; Obiye, 3,092,844; Kamaishi, 2,637,396; Makimine, 2,241,389; Yaguki, 2,222,201; Kunitomi, 2,216,736; Arakawa, 2,077,409; Hibira, 1,742,165; Yusenji, 1,852,145; Yoshioke, 1,678,141; Nagamatsu, 1,424,246; Okura, 1,543,141; Hisaichi, 1,351,764; and 37 other mines producing less than 1,333,000 lb. each, 13,910,013; making a total of 139,676,531 pounds.

Coal. Muke, 2,226,700 short tons; Tagawa (Mitsui's), 1,092,285; Onoura, 880,000; Yubari, 774,400; Minenoike, 737,250; Futase, 660,500; Iriyana, 596,300; Yoshinotani, 575,000; Meiji, 550,700; Hokoku, 537,000; Namazuta, 522,000; Shinnyu, 468,500; Tadakuma, 454,100; Shiozumeo, 449,300; Yamano (Mitsui's), 446,000; Uchigo, 416,100; Aichi, 404,000; Kanada, 366,400; Shin-Yubari, 364,900; Matsushima, 351,000; Hondo (Mitsui's), 346,260; Koma, 343,400; and 59 other collieries producing less than 333,000 tons each, 8,099,115; making a total of 21,695,071 tons.

Sulphur. Horobetsu, 24,472,654 lb.; Numakiri, 24,314,530; Okushiri, 23,357,224; Kobui (Mitsui's), 21,593,009; Iwaonobori (Mitsui's), 20,766,445; and ten other mines producing less than 6,666,000 lb. each, 36,244,533, making a total of 150,548,300 pounds.

Petroleum. Nugata-Ken, 1,680,000 bbl.; Akita-Ken, 620,000; Shizuoka-Ken, 1370; Hokkaido, 3840; Taiwan (Formosa), 14,950; and other *kens* (prefectures), 616,080, making a total of 2,936,240 barrels.

A gold nugget found in 1900 in the placer workings of Esashi, on the northern coast of Hokkaido, weighed 205 momme (24.7 oz.), and was said to be the largest nugget ever found in Japan. But a nugget recently found at Tansen, Kankyo-Nando, Korea, is much larger than this, as its weight is 245 momme (29.5 oz.). It was bought by the Chosen Bank for 1100 yen, and is now on exhibition in that institution.

New System of Mining Coal at Dawson, New Mexico

On October 22, 1913, an explosion at the Stag Cañon Fuel Co.'s No. 2 mine resulted in the death of 256 men. This was caused by the ignition of dust during working hours through a badly directed shot, fired against the most rigid rules. In 1914, according to the annual report just issued, only five men were killed in the mines in the production of 1,355,938 tons of coal. According to the general manager, T. H. O'Brien, the following system has been devised:

In order to confine explosions, which in spite of every precaution are liable to accompany coal-mining, to the smallest economical area it has been decided to reduce the size of each mine to an average daily production of about 750 tons. Underground work, therefore, during the past year has been laid out with that object in view. In carrying out these improvements, barriers are being built, dividing No. 2 mine into what will hereafter be designated as mines No. 2 and No. 3. Similar subdivisions are being effected in No. 1 mine and in No. 5 mine.

In carrying out these precautionary measures the removal of the pillars formerly left between the rooms has supplied a large proportion of the year's output, and our experience has led us to decide upon a rather radical change in our methods of mining.

The plan, after a fair practical test, is to drive entries to the boundaries before turning rooms, and it has worked so satisfactorily that it is in contemplation to adopt this modification in all of the mines. This will hereafter result in recovering all the coal at one operation, and secure the advantages of the long-wall system of mining. If unforeseen obstacles should present themselves, there will be no difficulty in returning to the room-and-pillar system if experience proves that to be the most satisfactory method.

One of the most serious conditions to contend with in these mines is the dry and dusty character of the coal. To reduce the sifting of fine coal from the old-fashioned cars with their end doors, tight cars are being substituted, and changes made at the tipples to discharge these tight cars from rotary dumps. This alteration has been made at the tipple of No. 5 mine, and the 200 tight cars already ordered will be used in that part of the property. As soon as possible, similar alterations in equipment will be made at the other mines. Before each of these tight cars starts on its journey from the heading, its contents are thoroughly sprayed with water to prevent the fine dust being picked up by the strong ventilating currents. To moisten the mine air, adjustable sprays have been devised, which are working in a most satisfactory manner.

In order to further increase the moisture, radiators have been installed at the entrance of the mines. The temperature of the air has to be raised and the steam and water discharged into the elevated temperature. For this purpose boilers have been installed at mines No. 1, 2, 3, and 5. Mine No. 4 is supplied from the tipple boiler-plant.

Previous to this year the miners loaded their holes and connected their rooms with the system of shooting wires. This practice has been discontinued, and special men now do the loading and make the connection after the men have left the mine.

Mining Costs at Goldfield Consolidated

In 1914, from the mines of this Company, there was stoped 282,936 tons of ore at the following cost:

Item.	Total cost.	Per ton.
Superintendence	$ 2,828	$0.010
Foreman	4,050	0.014
Shift-bosses	11,190	0.039
Miners	123,651	0.437
Shovelers	117,949	0.416
Trammers	36,409	0.129
Timbermen	65,448	0.231
Cagers	10,575	0.038
Hoistmen	16,902	0.060
Top carmen	19,189	0.068
Shaftmen	11,062	0.039
Pumpmen	3,056	0.011
Nippers	8,922	0.032
Filling labor	70,633	0.250
Blacksmiths	6,022	0.021
Blacksmiths' helpers	999	0.004
Carpenters	3,632	0.013
Watchmen	3,727	0.013
Miscellaneous	16,480	0.058
Total labor	$532,723	$1.883
Timber lagging	$130,600	$0.462
Explosives	26,380	0.093
Illuminants	6,862	0.024
Drills, fittings	6,558	0.023
Pipe, fittings	1,200	0.004
Track, fittings	789	0.003
Cars, repairs	575	0.002
Iron, steel	1,532	0.006
Lubricants	1,158	0.004
Tools	2,230	0.008
Sundries	11,747	0.041

Grand total	$806,879	$2.852
Per cent of total underground		78.58

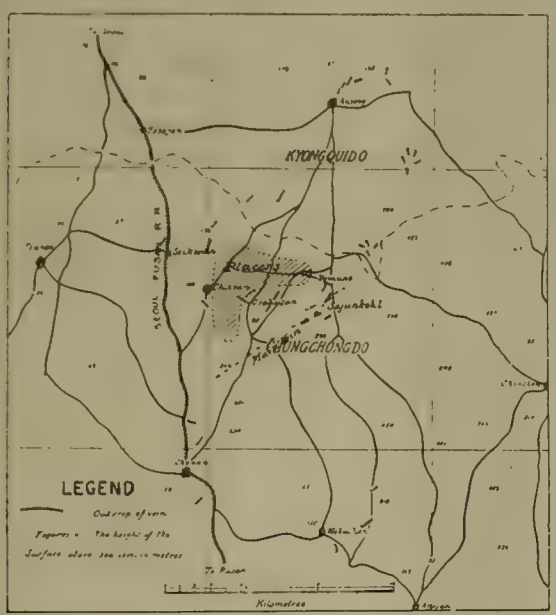
Development, which amounted to 30,028 ft., brought up the underground cost to $3.411 per ton, or 21.42% of the total of $1,026,808. Cross-cuts cost $7.52 per foot; rises, $6.62; winzes, $14.26; and diamond-drilling, $5.02 per foot for 379 ft. Timbering cost 73.6c. per ton; tramming, 13.6c.; hoisting, 20c.; pumping, 2.4c.; and surface charges, 17.8c. per ton.

Cyanide Plant of the Chicksan Mines, Korea

By CHARLES W. De WITT

*The ore treated at the reduction plant of the Chiksan Mining Co., Korea, is brought from four of the company mines, and from the small tribute mines. The largest shipments come from the Sajunkohl mine, situated about a mile and a half from the mill. The ore is quartz of medium hardness. The average assay-value in gold is $6.95 per ton. At the mine the ore is put into bins, and is then trammed over an 8% grade to the tipple-bins above the mill, where it is drawn through the mill-holes as desired. The capacity of the bins is about 3500 tons.

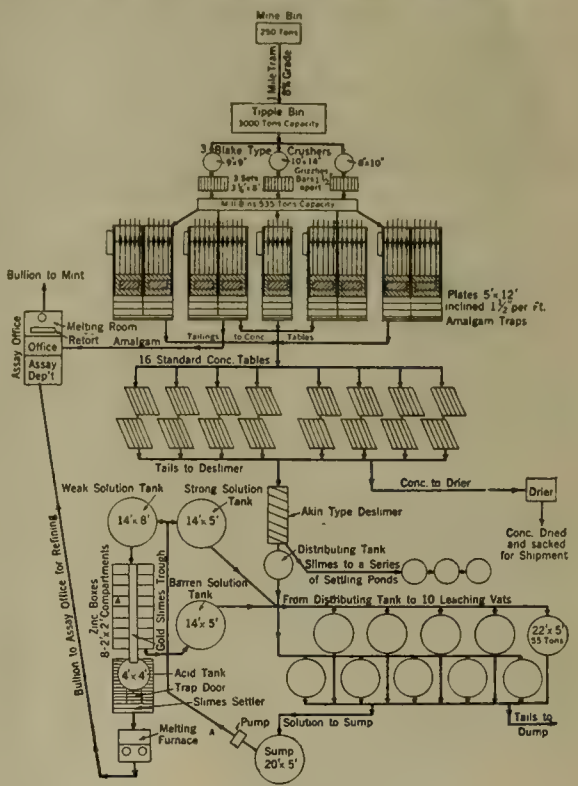
Ore from the Moonsukohl, Chung Tarrie, Yang Chun,



MAP OF CHICKSAN MINING CO. PROPERTY.

and the tribute mines is brought in by bulls and bull-wagons. The bulls carry from 350 to 800 lb.; the average wagon-load is about 1200 lb. One shovelful of ore out of every ten is taken as a sample. Considerable ore is brought from the outside mines, and this method of sampling is used to avoid mixing the lots. However, a series of bins will be erected in the near future and an automatic sampling-device installed so that the ore can be handled to better advantage.

Since 1907 our plant has been enlarged from a two-stamp to a 45-stamp mill. The course of the ore through the mill is shown in the flow-sheet. From the tipple-bins it is drawn through chutes into 1¼-ton cars and trammed to the mill, where it is dumped over grizzlies, 3¼ ft. wide by 8 ft. long, the bars being set 1½ in. apart. The oversize goes to three Blake crushers of the following sizes: 9 by 9, 10 by 14, and 8 by 10. The crushed ore drops direct to the mill-bins; it then gravitates through 9 Challenge feeders, which supply the 9 batteries. The stamps weigh 1250 lb. each and are operated at 100 7-in. drops per minute. The distributed



FLOW-SHEET OF MILL.

weight of the stamp is: stem, 610 lb.; tappet, 150 lb.; boss-head, 300 lb.; and shoe, 190 pounds.

The ore is crushed to 30-mesh, and is then run over amalgamating-plates, both inside and outside amalgamation being used. The plates are 5 by 12 ft. and have a slope of 1½ in. per foot. The pulp passes from the plates into Pierce amalgamating traps, and from the traps is distributed to the first series of eight concentrating tables. The middlings from these tables go to another series of eight tables on the floor below. The concentrate is dried, sacked, and shipped to the United States. After the completion of the de-slimer, the tailing will be run direct to vats in the cyanide plant; at present it is stacked before cyanide treatment.

In August 1913 the cyanide plant commenced operations. At that time six vats, 22 ft. diam. by 5 ft. deep, with a capacity of about 55 tons of damp sand, were

*A paper to be presented at the September (San Francisco) meeting of the American Institute of Mining Engineers.

used for leaching; during the year it was necessary to add four more vats of the same type to handle the mill-tailing. An Akins de-slimer is being installed and will be ready for operation early in 1915. The sand will then be run from the de-slimer through a rotating launder-distributer, which will supply the vats; slime from the de-slimer will be run into a series of settling-ponds, and if found to contain sufficient gold, will be cyanided after a large enough amount has accumulated.

At present the vats are filled and emptied by coolies, carrying 'jiggies.' This is an uncertain method, for when the planting and harvesting seasons come the coolies go to work on the farms, leaving the cyanide plant short-handed. For this reason the plant can be run to its full capacity only a few months of the year.

The sand in the leaching-vat is first treated with a 0.2% solution of potassium cyanide, supplied to the vat through a $2\frac{1}{2}$-in. pipe from the solution-tank. After about 7 hr. the solution is drained off, and while draining a 0.1% cyanide solution is run in; this is drained after a few hours, and at least two washings of water applied. The vats are then unloaded and prepared for a new charge, four days being taken for total treatment, including the loading and unloading of the vats.

The pregnant solution is pumped to the receiving-tank from which it flows to two 8-compartment zinc-boxes, having a total length of 20 ft., with compartments 2 ft. square. Zinc-shaving is used as the precipitant. The solution from the boxes is run into the barren-solution tank, and is then pumped up to the strong-solution tank, where it is made up to the required strength.

The gold slime is cleaned from the boxes and run into the acid-tank, where for three days it is treated with sulphuric acid. The slime is then run into a vacuum-settler and drained; after which it is dried over a large iron drying-pan, weighed, and melted, the resulting button being sent to the assay-office for refining and assaying.

The performance of the mill for the year ended December 31, 1914, was:

Tons crushed	46,402
Average assay-value	$6.956
Gross value (head assays)	$322,770
Bullion (21,872 oz.):	
Gold	$231,932
Silver	5,794
Concentrate (414.33 tons)	31,388
Total	$269,114
Milling cost, per ton crushed	$0.67
Average assay-value of concentrate	$75.75
Stamp-days	11,190.24
Stamp-duty per 24 hours, tons	4.12

The costs and recovery at the cyanide plant for the year 1914 were:

	Per ton.	Total.
Recovery	$0.799	$29,426
Cyaniding cost	0.335	12,462
Profit	$0.464	$16,964

Total recovery from reduction plant was:

Bullion (28,105.6 oz.):	
Gold	$259,013
Silver	8,062
Concentrate	31,388
Total output	$298,463

Water for the mill is brought from the creek through a small ditch about a mile long. During the summer or dry season the water-supply was insufficient to run the mill, so it was necessary to make settling-ponds; the water from these ponds is pumped back to the mill. The mill is operated by a 300-hp. Russell compound engine, which also drives a 75-kw. alternating-current generator, which in turn drives the other small 5 and 10-hp. motors and supplies the lighting service for the mine and camp. Power for the engine is supplied by three 150-hp. boilers.

PUBLIC INTEREST in the statistics regarding imported potash salts is keen, according to *Commerce Reports*, published at Washington, D. C., both by reason of their wide application in the manufacturing and other industries and the fact that the United States is still dependent on foreign countries for practically the entire supply thereof. The following table shows the imports of potash salts during February 1915 compared with that month last year. The figures are so grouped as to show those potash salts used chiefly as fertilizers, which are entered by the long ton, and those which are used in the arts and chemical industries, of which the unit of quantity is the pound.

	February 1914.		February 1915.	
Class of salts.	Quant.		Quant.	
Fertilizer salts:	Tons.	Value.	Tons.	Value.
Kainit	72,008	$321,723	1,852	$ 18,445
Manure salts	12,451	124,422	900	14,748
Sulphate of potash	5,098	210,327	1,378	59,804
Muriate of potash	13,172	431,820	22,818	836,368
Other potash salts:	Pounds.		Pounds.	
Carbonate of potash	1,674,685	49,110	1,317,849	46,015
Caustic potash	520,166	19,607	308,805	17,508
Nitrate of potash	22,699	928	.....	.....
Cyanide of potash	5,641	890	266,654	39,327
Other potash salts	638,112	52,119	456,011	42,429

THE EXPLOSION at the New River & Pocahontas Coal Co.'s mine near Layland, West Virginia, on March 2, killed or imprisoned over 160 men, and one was killed on the outside of the mine when passing the entrance. The chief mining engineer of the U. S. Bureau of Mines, George S. Rice, has written a paper on the rescue of 42 entombed men. The run of rescue-car No. 8 (133 miles in 196 minutes), work of the oxygen-apparatus crew, repairs to fan, the way the men bratticed themselves off from the rest of the mine, and other interesting events are all described. The recovery of the entombed men furnishes a splendid illustration of the wisdom of men who have escaped the direct violence of an explosion in bratticing themselves off, when the exits are filled with afterdamp; and of the importance of their keeping calm and collected under the trying conditions which prevail following an explosion.

CONCENTRATES

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Chemicals and supplies at the Nipissing low-grade mill cost $2.0457 per ton of ore treated in 1914.

Native mercury is often found in quicksilver mines; it is due to the reduction of cinnabar by acid waters.

Uranite is the hydrated phosphate of copper and uranium. It contains 61% uranium and 9% copper oxide.

Decorated glass is made by painting the surface with easily fusible glazes. After drying the glass is put in a kiln and heated sufficiently to fuse the glaze.

Platinum is derived entirely from detrital or placer deposits, but in the Ural region it has been traced to its source in dunite, an olivine rock rich in chromite.

Florence zinc is the name applied to the oxides of zinc made by the French process. The best known of these products are produced by the Vieille Montagne.

Chrome brick is advised as an interior lining of blast-furnaces for copper smelting at high altitudes, that is, over 10,000 ft., because such brick retards radiation and consequent freezing.

Analysis of subway dust in New York gave the following contents: metallic iron, 46%; iron oxide, 14.5%; lime and plaster, 12.1%; grease, 1.12%; and water and organic matter, 12.6%.

Feldspar, not felspar, is the correct spelling. Dana says that the dropping of the 'd' is "bad orthography." It arose from an error made in Kirwan's 'Elements of Mineralogy,' published in 1784.

Slag cement is made by chilling the slag by a stream of water, it is then mixed with slaked lime and finely ground. Lately cement has been made by mixing the ground slag with portland cement.

Counterforts are increases in the thickness of a wall or dam made at regular intervals for the purpose of strengthening it. Some civil engineers believe that they are ineffective for this purpose, and insist that a greater increase of strength would be produced by using the the same amount of masonry in increasing the thickness of the wall throughout its length.

Silver and mercury are lost to some extent in melting at the Nipissing refinery at Cobalt. Experiments are being conducted with the Cottrell process on the fume from the furnace, with a view to reducing losses.

Carnotite contains both uranium and vanadium. In a pure state it averages 63% V_2O_3, 20% V_2O_5, 10% K_2O, and 5% H_2O, but it is usually mixed with silica. It is a commercial mineral in Montrose county, Colorado.

More than 3000 technical articles dealing with almost every conceivable phase of nitrogen fixation have appeared in different languages. The patents applying to the subject in all its branches number into the thousands.

Creosote lowers the crushing strength of mine-timbers, especially if heat is used during the treatment. Cold saturated brine is a good fire-proofing material and has the least injurious effect on the crushing-strength of timber.

London price of spelter in pounds (£) per ton, if divided by 4 gives the New York equivalent in cents per pound, including the duty payable. This does not include any allowance for freight. Shillings and pence should, of course, be calculated as decimals of a pound.

Neat's foot oil is made by boiling the feet of cattle in water. It is an excellent lubricating oil, but is chiefly used in the manufacture of leather, and is frequently adulterated with other oils, since it is comparatively expensive. It takes its name from the old-Saxon word 'neat,' meaning ox or cow.

Moving pictures are dependent on chemical industry, since the transparent films are made from a solution of pyroxylin, or nitrated cotton, and camphor in wood alcohol or amyl acetate. This solution is poured on a smooth glass plate and allowed to evaporate, yielding a flexible and transparent film. It is estimated that the world's

production amounts to 200,000 sq. ft. of film daily. Their manufacture in the United States is controlled by patent No. 610,686. In the settlement of a recent infringement suit between $30,000,000 and $40,000,000 was paid.

ALLAYING DUST is of great importance in Rand mining, where water-drills, water-blasts, and water-sprays are used for the purpose. The first are used wherever practicable, blasts are used in development work, and sprays are placed at those points in the underground working where traveling dust might be expected.

UNDERGROUND crushing-stations are in operation in several important mines. The system reduces costs. It is gaining in favor. The latest property to have such a plant is the Dome at Porcupine. On the 425-ft. level of No. 2 shaft, a 36 by 54-in. Buchanan jaw-crusher, grizzly, 500-ton bin, and another crusher will reduce the ore for the stamp-mill. In March, this mine yielded 23,220 tons averaging $4.20 per ton.

TWO NITROGENOUS COMPOUNDS, nitrate of soda and sulphate of ammonia, constitute in value 80 to 85% of the total raw nitrogen compounds produced throughout the world. The value of their combined production in 1913 was between $190,000,000 and $200,000,000. It is estimated that 80% went to agriculture, corresponding to an annual per capita tax on the 600,000,000 inhabitants of the earth of 33 cents.

PROSPECTING by hydraulicking is a feature at the Nipissing mine, Cobalt. In 1914, 95.55 acres was washed at a cost of $499.47 per acre. The cost per cubic yard was 9.01c. Average depth of soil was 3.43 ft. There were 153 set-ups made, 35,540 ft. of 16-in. pipe taken up, and 33,769 ft. laid down, and 18,730 ft. of road constructed. The average pressure at the nozzle was 138 lb. The pump worked 79% of the possible time. Little ore was uncovered.

RE-GRINDING at the Winona copper mine in 1914 showed the following results:

Ore stamped, tons	123,339
Sand re-ground in Hardinge mill, tons	59,500
Costs:	Cents per ton ground.
Power, 1.054c. per kw.-hour	13.64
Labor	0.65
Pebbles, 0.8c. per pound	2.08
Silex lining at 1.436c. per pound	0.09
Steel lining at 5.242c. per pound	0.33
Sundry charges	0.43
Total	17.22
Cost per ton stamped	8.31
Cost per pound of copper obtained	3.86

COAL-TAR is a black oily liquid that separates from the gases produced in the destructive distillation of coal. It consists of light oils, pyridine bases, phenols, naphthalene, anthracene, heavy oils, pitch, complex organic compounds insoluble in benzene, water, ammonia, and dissolved gas. It is refined by removing the water and more or less oil by distillation, and may then be used to saturate roofing felt, to coat roofs, as a cheap paint, and for applying to wood that is to be buried in the ground. For the making of by-products it is distilled; yielding crude naphtha, heavy oil, dead oil or creosote oil, and pitch. From the first, benzol, toluol, naphtha, and a residue that is added to the second are made. Among the great variety of products made from the other three are phenol, cresol, ortho-cresol, meta-cresol, and para-cresol, xylenol, naphthalene, and anthracene. From these an almost infinite number of organic chemical products can be made.

CONSIDERABLE confusion exists, in the mining world especially, as to the meaning of the word 'tamping.' It originally included the compressing of a charge of explosives in the borehole, also the compressing of the inert material used to confine the explosive charge in the borehole so that it would not blow out. This tamping included the ramming of the powder itself so as to compress it as tightly as possible, to fill all the available spaces in the bottom of the borehole. With black-powder charges the clay, sand, or earth is also packed in as tightly as possible, as there is little chance of obtaining the full power that the black powder is capable of generating unless it is packed in and confined as tightly as possible. The earth, clay, etc., was also termed tamping. When dynamite and permissible explosives appeared, it was quickly recognized that they would not require to be compressed as tightly as the blasting-powder charges. To attempt to do so was highly dangerous. It was found, however, that the confining of the charge was as necessary in some kinds of work as confining of the black powder charge, and especially with permissible explosives. The compressing and forcing of the charge into the borehole being eliminated, the word 'tamping' came to mean the inert material used for confining the explosive in the borehole, according to the *Dupont Magazine*. In England, and in the literature of the U. S. Bureau of Mines, the word 'stemming' has been used to designate the clay, sand, or other inert material used to confine the charge of explosives, whether the explosive is blasting-powder or a high explosive. It is rather desirable that this word be used in this connection to avoid confounding it with the pounding of the explosive charge itself. When a manufacturer strongly recommends that the charge of permissibles be thoroughly 'tamped,' it means that the explosive charge shall be placed carefully and without forcing in the borehole, and the inert material be placed on top, at first placed lightly in place. After this it can be packed as tightly as can be done by pressure alone, without ramming, with a light wooden stick. If the word 'stemming' were used exclusively to designate the inert material for confining a charge of any explosive and the process of placing this material and packing it firmly in the borehole, a dangerous confusion of terms would be eliminated.

Nevada Minerals at the Exposition

This state is chiefly known on account of its mineral production. In 16 counties there are about 190 mining districts, containing nearly 800 producing properties. In 1913, a normal year, 5,367,211 tons of ores from 786 mines, yielded 570,589 oz. gold, 16,090,083 oz. silver, 90,693,751 lb. copper, 16,344,023 lb. lead, and 14,419,671 lb zinc, valued at $37,097,710.

In the Palace of Mines and Metallurgy at the Exposition, the display of Nevada minerals is excellent. It is neat and attractive, a credit to those who designed and arranged the booth. More than this, it is instructive. Just above the floor at the main entrance is a large map of the state in relief. The numerous north and south ranges and valleys are a feature of the topography. At the back of the booth are colored cubes representing the output of the various metals. A map shows the mining districts. Cases containing exhibits line the walls. Production charts show the yields for 10 years. Other charts show the yield per head of population. There are numbers of district maps, geologic sections, panoramic views and flowsheets of the important mills. The glass models are instructive. The Buckhorn mine is shown down to the 250-ft. level. The Nevada Hills is visible to No. 15 level. Part of the Goldfield Consolidated is on view. From National comes a horizontal and topographical view of the National mine, also a cross-section of the Charleston Hill. Methods of mine-timbering are shown by a model of the square-set system devised by Philip Diedesheimer at the Comstock. This is the original model. It has been exhibited elsewhere several times. There is also a model of the diamond triangular set at the Belmont mine, Tonopah. The Mackay School of Mines sent a head-frame, which was made there. As there are about 300 samples exhibited from mines and prospects, it is impossible to name them all.

Two of the show-cases contain high-grade gold ores from all over the State. Several polished pieces are exhibited by E. C. Smith. Stall Bros. of Humboldt county have $1500 ore. The Seven Troughs Coalition sends rich ore. Some malachite bloom is interesting. Polished Ludwig ore shows its structure. In the early days of Candelaria the assay-buttons were not parted, consequently a large amount of gold was not paid for. Some of these are shown by H. F. Whirlow. A small specimen of platinum ore from the Boss mine in Clark county is on view. This development last year caused considerable discussion. Two exhibits of miniature mining tools by G. L. Kennedy of Tonopah, and W. F. Reid of Goldfield, are worthy of mention. They show skilled work in their manufacture.

Tube-mill pebbles have been discussed frequently in the *Press*. Most of them used in America have come from Europe. Now the supply for Nevada is available from the American Onyx Co.'s quarry and plant at Manhattan. Rough and finished pebbles are shown.

What are termed the mineralogical cases in the exhibit contain interesting specimens from widely-separated districts. They include copper, antimony, sulphur, coal, graphite, wolfram, molybdenite, nickel, opal, salt, mica, diatomaceous earth, alunite, gold, silver, iron, platinum, and tin. Structural materials are building stones and gypsum. In connection with the last named, it might be stated that most of the plaster used at the Exposition came from the deposits at Mound House in Storey County.

The other displays in the booth consist of cases, each containing the individual rocks, ores and mill products of the large mines, as follows: Nevada New Mines Co., Rawhide; Goldfield Consolidated Mines Co., Goldfield; Jumbo Extension, Goldfield; Nevada Wonder, Wonder; Rochester district rocks and ores; Seven Troughs Coalition, Lovelock; National Mines Co. National; Consolidated Nevada-Utah Corporation (controls Amalgamated Pioche); Round Mountain Mining Co.; Nevada Bunker Hill Mining Co., Bullion; Nevada Consolidated Copper Co., Ely (on a stand by itself is a slab of 99.5% copper weighing about 500 lb.); Buckhorn Mines Co.; Nevada Hills Mining Co., Fairview; and Mason Valley Mines Co. To those interested in quicksilver, the exhibits of the Nevada Cinnabar Co., at Ione, Goldbanks Mercury Co., at Goldbanks, and Mercury Mines Co. at Ione, are of great interest. Cinnabar occurs in rhyolite, quartzite, and limestone respectively. Near Mina some ore occurs in limestone. The exhibits include furnace charge, residue, condenser sublimate, and quicksilver. At Ione the Scott furnace is used, and at Goldbanks the Adamson. The Tonopah Belmont Development Co. exhibits average and rich silver ore. In a small case is some briquetted precipitate, and bar No. 1915, weighing 2050 oz. MacNamara Mining & Milling Co., West End, Montana, and Tonopah companies are together.

Comstock men will be disappointed in the display from the lode which has yielded nearly $400,000,000 in silver and gold. It includes crushed timber, the Burleigh drill (the first Rand machine used, weighs about 500 lb.) compared with the latest type, a large piece of ore from the Mexican mine, and silver-gold ore from 1650 and 1950 ft. in the Con. Virginia, and 2100 ft. in the Ophir. The mining booth is in charge of J. H. Price.

Minerals of New Zealand at the Exposition

New Zealand is essentially an agricultural country. In 1914, its population of about 1,100,000 people exported materials valued at £26,261,447. Of this, metal and minerals was £1,674,974. In 1913 the mineral production amounted to £3,187,191. The total to date is approximately £124,000,000. Gold and silver contributed £85,500,000; coal, £21,000,000; and kauri gum, £17,000,000. The balance of £500,000, distributed over several other minerals, shows that little attention has been paid to them. Some occur in small quantities, and one or two as large deposits. Apart from these facts, several mines in New Zealand are great producers and have attracted world-wide interest.

In the Palace of Agriculture at the Exposition, the exhibits of agricultural products from the Dominion of New Zealand loom large against the small mineral display. The latter includes the following: gold-silver ore from the Thames district, which has a production of £7,000,000; the Waihi, Grand Junction, and Talisman mines in the North Island; and the Blackwater, and New Big River mines in the South Island; also auriferous gravel from Ross Flat, and gold-bearing black sand from Hokitika, the latter has produced several million pounds worth of gold to date; gold conglomerate from the Golden Crescent mine at Weatherstone. Gold scheelite from the Dominion mine; samples of coal; kauri gum of all grades in the E. Mitchelson and other displays; iron ore from Parapara, where is about 64,000,000 tons of good grade material; iron-sand from Taranaki, where the beaches contain enormous quantities of good grade; silver-telluride ore from the Silverstream mines, sulphur from White island and hot springs in the Taupo region of the North Island; oil, refined products, wax, and coke from the Taranaki Oil Wells Co.; oil-shale from Orepuki; cinnabar from Mackaytown, near Karangahake and Waihi; manganese ore from south Wairoa; copper-molybdenite ore from Mt. Radiant; silver-lead ore from Wangapeka; phosphate rock from Clarendon, Otago; native copper from Aniseed valley; Greenstone from Westland; Wilson's portland cement; and granite, marble, and limestone for building, including the well known Oamaru stone.

Final returns from the Hauraki peninsula of the North Island in 1914, show that the yield of gold and silver was worth £913,953. This is an increase of £53,505. The Waihi-Karangahake districts contributed £875,734 of this amount. The banner year was in 1910, when they produced $1,296,115.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

TORONTO, ONTARIO

ASSESSMENT WORK MUST BE DONE.—DOME, JUPITER, REA, PIKE LAKE, PORCUPINE PET, PEARL LAKE, LA ROSE, SALVADOR, TEMISKAMING, AND RIGHT OF WAY MINES.

A stimulus to development has been given by the decision of the Lands, Forest, and Mines Department of Ontario to allow no further extension of time for assessment work on claims. Last year, on account of the War and the financial depression, the Government relaxed the stringency of the mining regulations. It provided that the period between August 15, 1914, and August 15, 1915, should be excluded in computing the time within which work should be done. The Government has had numerous requests for a further extension. It is now officially announced that these will not be granted. This decision will tend to relieve the unemployed situation that has for some time presented a serious problem. It will encourage prospecting and development.

At the Dome mine, Porcupine, electric storage-battery locomotives, hauling cars carrying 5 tons each are to be used to

PROSPECTING BY HYDRAULICKING. THIS IS A FEATURE OF SURFACE WORK AT THE NIPISSING MINE, COBALT.

collect ore from the stopes.——The Jupiter, which has been closed down since the McKinley-Darragh company abandoned its option last fall, has contracted for a supply of power. It will be shortly re-opened. It has a small orebody blocked out on three levels.——At the Rea, now operated by the Mines Leasing & Mining Co., a diamond-drill is putting in flat holes on the 300-ft. level. The mill is treating 40 tons per day. The extraction is about 86%.——Highly satisfactory results of development at the Pike Lake are reported. The vein on which the shaft is being sunk shows a width of 18 ft. Assays are high. Several veins in the property show free gold.——The Porcupine Pet has closed down. The company has made a voluntary assignment to creditors. A 5-stamp mill has been saving some gold during the last year. Working costs have been heavy on account of the ore being spotty.——A plan is on foot for the financial re-organization of the Pearl Lake. It is proposed to organize a new company capitalized at $2,500,000 to offer 2,000,000 shares to shareholders in the proportion of 400 new to every 500 now held, at 11c. per share. This money will defray the Company's liabilities amounting to $220,000. The remaining $500,000 will provide funds for further development.

The annual report of La Rose Consolidated was discouraging. Exploration work undertaken last year has resulted in no important discoveries of ore. The properties have been almost exhausted of high-grade ore. Ore reserves have been reduced to 859,919.——The Temiskaming & Hudson Bay has secured an option on the Wright claims, known as the Salvador property. It contains a smaltite vein carrying low silver content. Development has been encouraged by the favorable results of work on adjoining properties.——At the Temiskaming the end of a rich ore-shoot has been found in an old drift on the 450-ft. level.——Work has been resumed at the Right of Way. Three drills are working. ——The Columbus is to be pumped out and operations resumed.

The Hon. G. Howard Ferguson, Ontario Minister of Lands, Forests and Mines, is making his first visit to the mining districts of northern Ontario, in order to familiarize himself with the conditions and requirements of the mining industry.

JOPLIN, MISSOURI

ZINC CORPORATION DRAINS LARGE AREA.—NEW ZINC SMELTING CO. ORGANIZED.—GOVERNMENT PROTECTS INDIAN LAND-OWNERS.

Four large pumps have been installed, and two more are to be, by the Zinc Corporation on its recently acquired tract of 770 acres situated in the centre of the south Carterville, Missouri, district. On the Luscombe land, which comprises a portion of the new lease, two 6-in. pumps are at work. In ten 24-hour shifts they lowered the water in the old mines to a depth of 180 ft. Mining was formerly done at this point. Work on this property was stopped many years ago. The main reason was the water. Through the draining of the Luscombe lease, a large part of the south end of the Cornfield lease also is drained. This will mean a resumption of work on this property. Two 4-in. pumps are working on the Ohio lease of the Burgner land, also held by the Zinc Corporation and included in the 770 acres. The water here has been lowered to the bottom of the old drifts, a depth of 175 ft. Deeper mining is contemplated. The two pumps yet to be installed will be on the Homestead tract. T. J. Franks, local manager for the Zinc Corporation, thinks that the entire tract will be drained by May 20. Several companies are planning to take sub-leases on the property.

S. Y. Ramage, who recently purchased 40 acres of the Schifferdecker land, also is interested in a new zinc smelter to be started at Pittsburg, Kansas. It will have a capacity of 300 tons of concentrate per week. The old North Pittsburg smelters have been taken over by the new company, which will be known as the Joplin Ore & Spelter Co. Only Joplin concentrate will be used. Turner & Co., of New York, are associated with Mr. Ramage in this venture. The plant will be arranged to run at full capacity by May 15. These smelters, which will have 1344 retorts, were last operated by the Cockerill Zinc Co. Another smelter at Pittsburg, Kansas, to resume operation within the past few weeks is that of the Pittsburg Zinc Co., owned by J. G. Starr, of Joplin, and the Lanyon interests of St. Louis. The plant has been leased to the American Metal Co. It is understood that Joplin ores will be used in conjunction with western ores.

Scores of speculators in Joplin, Galena, and Baxter Springs, Kansas, Miami, Oklahoma, and other cities of the Missouri-Kansas-Oklahoma zinc and lead district, are affected by the decision of the Supreme Court of the United States. This

reverses the decisions of lower courts relative to the rights of Indian land-owners to sell their royalty rights in mining properties. The lower Courts held that the Indians could barter their royalty rights as they wished. The Supreme Court prevents the Indians from so disposing of their rights. It provides that suit may be brought against those who have purchased such rights to force them to return the money they may have received from royalties. The Indians were found, as a rule, to be willing to dispose of their rights for ridiculously small sums. A state official of Oklahoma is owner of a right which he purchased for $300 from an Indian named Arthur Buffalo, a Quapaw. On this lease is situated the famous Turkey Flat mine, the royalties from which have aggregated almost $100,000 since the Quapaw relinquished his rights to it. The Court also maintains that overlapping leases are void. It was the custom of lessees to procure renewals each year from the Indians. The Court holds that the leases expire at the time specified in the first lease taken out. This will affect many large lease-holders who procured leases about 10 years ago, and who have been renewing them for periods of 10 years each year or so, following the procuring of the first lease.

Morrison & Co. have sold their soft-ground mine on the Connor land, south of Webb City, Missouri, to T. F. Coyne. He will immediately begin construction of a mill to replace the old hand jig-plant that has been in use at this property for several years. Although this lease is surrounded on three sides by hard, sheet-ground mines, the ore formation at this immediate property is in soft ground requiring heavy timbering. The ore occurs at 235 ft. This is about 30 ft. deeper than the level of the customary sheet-ground development at the surrounding properties.

The initial turn-in of concentrate has just been made from the remodeled mill of the Jasper County Mining Co.'s No. 1 plant on the Connor land, south of Webb City. Operations are conducted at 220 ft. in sheet-ground. The mill, which has a capacity of 300 tons, is practically new. The old plant had not been operated for many years. Formerly it was worked under the name of the McKinley Mining Company.

G. L. Cole is constructing a 300-ton concentrating plant on the Calumet lease, west of Neck City, Missouri. Mining is conducted in soft ground at a depth of 180 feet.

Firm zinc-ore prices at $55 to $60, basis of 60% metallic zinc, are stimulating much small activity throughout the district. Operators are looking for better ore prices in view of the strength of the spelter market.

CRIPPLE CREEK, COLORADO

New Leasing Company.—Ore in the Trail.—Elkton.—Drainage.—Isabella.—Portland Lessees.

The Cripple Creek Deep Leasing Co. is the name of a new syndicate in this district. It was organized by H. A. Riedel and A. P. Mackey of Denver. It has leased the ground between the sixth and eighth levels of the Jerry Johnson mine.

The Trail mine, whose west side-line parallels the Cresson, but which has been idle for some time, is back on the list of shippers again. Chris Eby and associates drove into this ground from the 1200-ft. level of the Dexter. They have opened a 4-ft. vein that returns about $100 per ton. They have now a stope nearly 100 ft. long on this shoot. Since the ore generally resembles the bonanza ore of the Cresson, great things are predicted for this lease.

The outlook at the old Elkton is bright once more. This is due to the good ore being mined on the No. 15 level. The cutting of another water-course in the Roosevelt drainage adit a fortnight ago lowered the water sufficiently to enable work on this level to proceed. The management reports the ore found to be most satisfactory. This mine is the next in line to be immediately benefited by the drainage adit. The contract now to be let calls for completing the adit to the Elkton shaft. The water at the end of April is receding in that shaft at the rate of six inches per day.

The Isabella is developing well again. On the ninth level of the Lee shaft, on the Buena Vista vein, or possibly on a vein parallel to it, a new shoot is yielding $25 per ton for coarse rock, and $150 to $200 for screenings. On the ninth level of the same shaft the Theobold lease is producing a good tonnage that will average 5 oz. per ton. The vein is well defined, and giving every indication of being persistent.

The Portland company recently decided to lease what is known as the tunnel level of No. 2 shaft. Several lessees have been successful in finding ore. One set, Miller & Co., have opened a vein one foot wide which assays about 20 oz. per ton. The stope now being cut will be 60 ft. long, with ore still showing in the face of the drift. The Portland company is working two shifts, employing about 400 men. It is keeping the local mill and that at Colorado City going full blast.

Lessees on the Vindicator are doing remarkably well just now, especially the Shatz lease on the 800 ft. level of the main shaft. This lease has been in operation about two years. It has brought splendid returns since the beginning. Another good one is the Brunner on the 1100-ft. level of the same shaft. Returns for this ore average $100 per ton continuously. The company is at work on the No. 17 and 18 levels in good ore. Average shipments on company account return between 2 and 4 oz. per ton.

SALT LAKE CITY, UTAH

Beaver, Salt Lake, and Summit County Notes.—Alta District.—Ohio Copper Company.

In Beaver county the Leonora mine in the Star district, situated between the Moscow and Cedar-Talisman mines, is doing some interesting work to expose the vein on the 400-ft. level. Production continues from the 150-ft. level.——The Rob Roy owners, who have been quiet for a long time, are entering on a development campaign due to some encouraging results of recent prospecting.

In the Alta district of Salt Lake county, the Cardiff mine, which was the scene of a rich development a few months ago, continues to be the centre of attraction. It has caused a considerable boom in that whole Cottonwood section. The limits of the orebody have not yet been determined. Net profits in sight are somewhere near $1,000,000. The company has shipped 1500 tons to date extracted in developing the orebody. This ore nets $30 per ton. On September 8, 1914, the stock sold for 3c., on April 26, 1915, it sold for $3.50. As the ore occurs on a limestone-quartzite contact that has been little explored, and is quite extensive, a good deal of the Alta excitement is justified.

A. S. Ross and others of the Pittsburgh-Idaho company have exercised an option on the control of the West Toledo Mining Co.'s stock. This property adjoins the Cardiff. The company will be re-organized.——The Michigan-Utah company has reorganized with a strong directorate. Bondholders took stock in the new company. The company owns 1000 acres, including the City Rocks and Grizzly veins. These are credited with a gross production of about $800,000.——The finding of high-grade ore in a rise in the Alta Tunnel & Transportation Co.'s property has aroused great interest. This tunnel, which crosscuts many of the best veins of the district at great depth, will be a great benefit in drainage, transportation, and prospecting. It is now 1200 ft. long. It starts in Silver Fork and Big Cottonwood, and heads almost due south for a point near the southern boundary of the Michigan Utah property, making a total contemplated length of 5000 ft. Among other veins it will intersect are the Prince of Wales, Richmond-Teresea, Alta Con., and Michigan-Utah.——By May 1 the Alta Con. and Wasatch mines will be able to use the roads for freighting ore.——The South Hecla expects to begin shipping on June 1.

The American Flag mine is to begin shipping to the Park

City mill, Summit county, next week. With the completion of this mill the American Flag now has a market for the low-grade ore developed in the past. Sommer Schmidt is in charge. The Thompson-Quincy Co. has reorganized under the name of New Quincy. Development is to be started. The property is well situated adjoining the Daly-Judge and Daly West.

The Ohio Copper Co., Salt Lake county, which has been in trouble, has apparently profited by having its copper tied up by the Court. The mine has been shut down by the Court for some months. Meanwhile copper has risen to 18 cents per

MAP OF UTAH.

pound, so that by this increase in value the company is much stronger financially than it was before. The Bingham Central Railroad Co. had a suit against the Ohio for $22,000. The Ohio had a counter suit for $135,000. The Salt Lake Engineering Co. had a suit for $36,000. Unsecured creditors also had a lien. There are promises of an early adjustment of the financial difficulties.

The Utah Metals & Tunnel Co. has come into the field as a shipper, the ore going to the Murray smelter.——There is unusual activity in Stockton. Lessees in the Hidden Treasure mine are keeping six ore-teams busy.

GOLDFIELD, NEVADA

TAILING TREATMENT.—JUMBO EXTENSION AFFAIRS.—ATLANTA VENTILATION.—PLACER GROUND.—BOOTH, ORO, SILVER PICK, KEWANAS, GREAT BEND.

With the dry weather, the Goldfield Consolidated will begin the treatment of its vast accumulation of tailing, a Lidgerwood cableway having been erected at a cost of $90,000 for the purpose of conveying this product back to the mill. Exhaustive tests throughout the large area of the tailing-pond indicate a return sufficient to insure a substantial profit from this source. Changes or additions to the mill-equipment for this operation involved little expense. The 100-stamp mill is treating a little over 1000 tons daily, the ore coming from the Mohawk, Combination, Laguna, Clermont, and Grizzly Bear mines, all of which are connected at various levels. From the Mohawk workings, on the 450-ft. level, drifts are being advanced into the Combination Fraction, which adjoins the Mohawk on the south, and is under lease to the Consolidated.

On the railway-spur at the Jumbo Extension mine, cars are being spotted for the shipment of some 300 tons of ore that has accumulated from development in extending the rich 524 drift. During April, 6 carloads, approximately 300 tons, was shipped to relieve the congestion in the bins. This ore yielded net returns more than sufficient to defray the operating cost for the month. Under the stipulations with the Booth company, entered into subsequent to the filing of the apex suit by the latter, all funds realized from production are impounded in the bank, but both companies have called special meetings of stockholders for the purpose of ratifying the agreement in settlement of this litigation, and immediately following such ratification the apex suit will be dismissed and all restrictions placed upon the Jumbo Extension company's operations will be removed. The dividend of 5c. per share, declared in January and payable to stockholders of record February 1, will then be paid, and it is probable that another dividend will be disbursed shortly. The capital stock of the Jumbo Extension company is to be increased from 1,250,000 to 1,750,000 shares, and out of the increase 300,000 shares will be transferred to the Reorganized Booth company in settlement for all claims of extra-lateral rights within Jumbo Extension territory. The latter company will resume operations with approximately $250,000 and 200,000 shares of stock in its treasury, and with a large tonnage of high-grade shipping ore available for immediate marketing. At the Velvet shaft, now 300 ft. deep, the new equipment is being installed, and sinking will proceed with all possible speed to a depth of 1017 feet.

In the Atlanta, air has been obtained for the workings on the 1750-ft. level by connecting vertical rise 1010-A, from the 1750-ft. level, with a winze sunk from the extended 1400-ft. level of the adjoining Grizzly Bear mine of the Goldfield Consolidated. Connection between the air-rise and the drift in ore, at the top of another incline-rise, 115 ft. above the 1750-ft. level, ensures good ventilation. Stoping will now proceed on this ore, with shipments for the present at from 30 to 40 carloads of 50 tons each per month. Drifts will be advanced into the Grizzly Bear claim, the south half of which, below the 1400-ft. level, is under lease to the Atlanta company.

Tests of the placer ground on the Sandstorm and Kendall groups have shown a gold content of from $3 to $10 per cubic yard over a considerable area, and for an average depth of 18 inches. Further tests to determine the best process of treatment have been delayed by storms.

On the 500-ft. level of the re-organized Booth, a drift near the foot-wall is progressing in ore sampling from $8 to $12 and of a character suitable for cyanidation. If any tonnage is developed here the product will probably be treated by the Goldfield Consolidated.——Goldfield Oro, adjoining the Booth, has exposed many seams of pay-ore in large masses of highly mineralized quartz, on the 700 and 800-ft. levels.——Silver Pick Con. has completed sinking its main shaft to 700 ft., and is cutting a station here, from which a cross-cut will be driven west for the shale contact and the large vein that dips toward the shaft.——At a depth of 840 ft. the Kewanas is extending drifts northwest and southeast along the latite-shale contact, the northern drift following a wide fissure that extends into the shale.——Development work is in progress on more than two dozen properties in the district.

The Goldfield Great Bend company has placed an order for new surface equipment, including a 6-drill compressor, a 42-in. by 10-ft. air-receiver, and a 75-hp. Westinghouse motor. The new equipment also includes a two-stage Cameron pump and new head-frame. The 75-hp. electric hoist has been installed at the vertical shaft, the unwatering of which will drain all the old workings. J. K. Turner is consulting engineer for the company, and work will be under the direction of Jack Campbell, who was in charge of the famous Reilly lease on the Florence and the almost equally productive Quartzite lease.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press

ALASKA

Cordova

A small dredge is to be constructed this season for C. Herron at Six-mile creek, Cook inlet, near Seward. The ground was prospected by a Keystone drill last year.

Fairbanks

A new Heilig stamp-mill has been started at the head of Fairbanks creek. A 14-ton lot from the Mizpah mine yielded $1150. Goyette and Ward, Hoover, Moreno, Huddleston, McNeil, and others have a fairly large tonnage to be crushed.

Juneau

March returns from the mines on Douglas island are as follows:

Details of operations.	Mexican.	Treadwell.	United.
Development, feet	373	1,130	1,238
Stock of broken ore	-16,653	-43,128	-16,572
Stamps working	120	540	270
Ore crushed, tons	19,985	76,787	43,547
Concentrate treated, tons	447	1,795	963
Total gold recovered	$40,733	$156,490	$93,433
Average per ton milled	2.04	2.03	1.85 to 2.55
Operating profit	$16,755	$70,931	$36,573
Construction	3,793	14,411	10,907
Net profit	12,962	56,520	25,665

Nome

In the *Press* of April 10, placer mining on the Seward Peninsula was discussed. Transportation in the Kougarok was mentioned. K. Knott and C. Philipson, dredge engineer and superintendent of the Kougarok Dredging Co., of Nome, returned to Seattle on the last trip of the *Victoria*. Contrary to the belief of many old-timers in the territory, particularly transportation men, the caterpillar engine, sent up last season to transport the company's freight, was a decided success. Freighters at Nome wanted $120 per ton for taking the dredge 65 miles into the Kougarok district. The Caterpillar transported 10 tons, or the first load of freight, for less than $20 per ton. It was hauled over ravines, gullies, and tundra, up 25 to 40% grades at 2½ to 3 miles per hour. Owing to the lateness of the season in getting into Nome, this company stored a considerable portion of the outfit, but is now prepared immediately to install and operate as soon as navigation opens in the spring.

ARIZONA

The local papers have been discussing the recovery of gold from various placer deposits of the State. They are all dry, and some method must be devised to treat them. Rich gravel occurs in the Plomosa and La Paz districts of Yuma county, Weaver in Yavapai, San Domingo, Leviston, and Old Hat in Maricopa, Quijota and Greaterville in Pima, and many others.

Cochise County

Officials of the Mascot Copper Co., whose mine is at Dos Cabezos, were in Douglas last week. According to Mr. McCauley, 1,500,000 tons of copper ore is blocked out. The Mascot and Western railroad from Wilcox to Mascot will be finished in about six weeks. Ore shipments, amounting to 200 tons daily, will be sent to the Copper Queen smelter at Douglas.

An increase of wages was announced at Bisbee on April 29. The average extra pay is 8%. About 6000 miners and smeltermen will be affected. The increase is due to the advance in copper.

Gila County

Construction at the Inspiration is proceeding at the usual pace. Concreting the main east shaft is practically completed. When the guides are in, the Nordberg hoists described in the *Press* of April 17 will be tested. The air-compressors are ready for work. They consist of two Ingersoll-Rand machines of 1400-cu. ft. capacity each for 100 to 1000 lb. pressure. The latter is for the Porter locomotives. Another I.-R. engine delivers 7000 ft. per minute. The other compressor is a Nordberg of 3000 ft. capacity. One of the three 3000-kw. Curtis turbo-generators was recently tested. The General Electric guarantees were beaten.

At the Iron Cap there are 25 men employed. Stoping is under way between the 650 and 800-ft. levels. Five cars of ore have been shipped. This contained from 8.45 to 11.80% copper.——The Calumet & Arizona company is preparing to mine at full capacity. The carpenter-shop at the smelter was burned on April 27. Damages are about $2000.——In the suit of C. A. Barrett *v.* the Ray Consolidated for $30,000, the plaintiff was awarded $500. He was injured in the mine at Ray, Pinal county. It was the first case tried (at Phoenix) under the State's employers' liability act.——The Old Dominion company at Globe has posted a notice regarding increased wages. Under the new scale a miner who at 15c. copper receives $3.75 per day will, with the metal at 16c., get $3.90; at 17c., $4; at 18c., $4.15; at 19c., $4.25, and all others in the same proportion.

A complete display of the minerals of Gila county will be the next attraction added to the headquarters of the Gila branch of the Arizona chapter of the American Mining Congress.

The International smelter, at Miami, is to be blown in on May 10.

Mohave County

It is reported that at a depth of 60 ft. in new ground, 400 ft. from the west boundary of the Gold Road mine, a wide body of rich ore is being opened.

Yavapai County

It is reported at Jerome that the Copper Chief company will erect a 150 to 200-ton stamp-mill and cyanide-plant. A large tonnage of ore has been developed.

CALIFORNIA

Gold and silver received at the San Francisco mint in April amounted to 374,680 oz. and 126,655 oz., respectively. This was from other besides California producers. Coinage executed was worth $2,231,500. The stock of bullion, etc., on hand at the end of the month totaled $280,142,358.77.

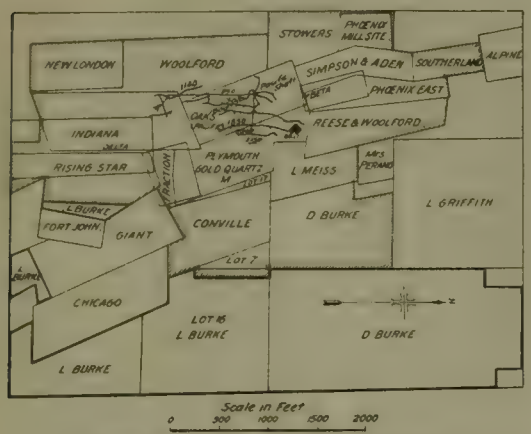
Amador County

On April 25 the Argonaut company paid its regular quarterly dividend of $60,000. The monthly output is about $60,000. An electric hoist is being installed at 3900 ft. in the incline shaft. The bottom level is at 4200 feet.

The report of the Plymouth Consolidated Gold Mines for the year ended December 31, 1914, has just been received from London. It makes interesting reading. Plans accompany it.

Development totaled 1816 ft., at a cost of 60c. per ton. Sinking and enlarging the main shaft (Pacific) curtailed this work. It is vertical to 1600 ft. Then it is inclined to 2150

ft. Cross-cuts were driven to intersect the drifts on the lode at 1850 and 2000 ft. Stations and ore-bins were cut at 1600, 1850, 2000, and 2150 ft. On the 1500-ft. level the main south drift was extended from 191 to 468 ft. From 300 to 392 ft. the vein was 77 in. wide, averaging $7.44 per ton. A rise above this level opened $5.28 ore over 79 in. width. At 2000 ft. the north drift averaged $6.48 per ton over 58 in. between 116 and 167 ft. The south drift opened $9.84 ore, 71 in. wide, between 48 and 121 ft. Stoping revealed greater widths of ore than were exposed by development on the various levels.



PLYMOUTH CONSOLIDATED PROPERTY. CLAIMS HATCHED, COMPLETELY HELD; DARK LINES, UNDERGROUND RIGHTS ONLY.

The grade has not been maintained over the increased widths.

Of the 44,773 tons of ore extracted, the following were the sources: development, 1455; surface dump, 3895; 950 ft., 1214; 1500 ft., 1510; 1600 ft., 14,530; 1850 ft., 15,073; and 2000 ft., 7096 tons. Mining cost $1.67 per ton.

The 30-stamp mill started in August. It treated 44,773 tons of ore. By amalgamation and concentration the yields were 5799 oz. gold and 1736 oz. silver, and 3654 oz. gold and 1133 oz. silver respectively. The yield was $4.36 per ton. The extraction was 88.24%. Tailing assayed 57c. per ton. Treatment cost 42c. per ton. Bullion and concentrate realization cost 29c. per ton. Revenue totaled $195,000. Costs totaled $3.26 per ton. A profit of $33,600 was made. Depreciation and other charges reduced this to $1060. Stores on hand are valued at $13,500.

Calaveras County

(Special Correspondence.)—The Finnegan and Finnegan Extension claims, at Carson Hill, four miles south of Angels Camp, have been acquired by the Carson-California Mining Co. This is composed principally of Denver men. The property has been under option for several months. A thorough examination has been made, including a 30-day mill-run. Results were so satisfactory that the present 10-stamp mill is to be doubled at once. A cyanide plant may be added. E. N. Hawkins is consulting engineer, and R. H. Toll superintendent.

Carson Hill, April 26.

Kern County

In commemoration of the twentieth anniversary of starting mining at Randsburg, *The Randsburg Miner* issued a special illustrated number on April 23. It states that there are nearly 100 gold mines in operation in the district. Short descriptions are given of the Yellow Aster, which has 100 stamps, the Black Hawk, Merced, King Solomon, Napoleon, Sunshine, Placer company's dredge, Consolidated, Red Dog mill, Baltic mill, Butte Lode, Atolia tungsten area, and the Southern Sierras Power Company.

Modoc County

Roads are being constructed to the Modoc mine in the High Grade district.——Some good developments are reported from the Quartzite, Tamarack, and other claims.

Nevada County

Construction material and machinery for the new mill at the Brunswick are arriving. The new railroad spur is proving useful in facilitating handling supplies. A cyanide plant is to be erected.

Concentrate from the Golden Center worth $10,000 is being treated at the Pioneer works near Nevada City.——Some good ore is being opened at 800 ft. in the Union Hill mine.

Plumas County

Two auto-trucks are now hauling copper concentrate from the Engels mine at Taylorsville to Keddie on the Western Pacific line.

It is reported that J. J. Reilly has sold a fourth interest in the Van Winkle claims for $20,000.

COLORADO

Gilpin County

At 1200 ft. in the Old Town mine, in Russell gulch, the Roberts and Hutchins lease has opened 12 ft. of rich gold ore for over 70 ft. A shipment of 25 tons to the Iron City mill returned about 6.4 oz. per ton.

Lake County (Leadville)

On April 26 the first water pumped from the Penrose shaft started to flow down Fourth street, Leadville. Great interest is being taken in this work.——Zinc sulphide ore mined here is being sold mostly to local buyers in the state.——The demand for manganese is increasing.——Lessees at the Hayden on Fryer hill are producing 20 tons of 22% carbonate of zinc ore.

Ouray County

In March the Camp Bird mine produced 2290 tons of ore. The profit was $36,000.

Teller County (Cripple Creek)

Smelters are now receiving 8% of the district's ore production. Formerly they handled only 5%.——The New York Trust Co., trustee under the mortgage on the properties of the United States Reduction & Refining Co., commonly known as the Mill Trust, has filed suit in the United States District Court for the appointment of a receiver on account of a default in the interest on the $2,650,000 of first-mortgage bonds outstanding. This means that all properties, including the Standard mill and the Colorado No. 2 mill at Colorado City, and the Union mill at Florence, will be sold. It will remove all chance of opposition to the Golden Cycle Mining & Reduction Co., recently reorganized by A. E. Carlton. These plants are out of date. The United States company was founded by Charles M. MacNeill and Spencer Penrose. The rates charged were so high that when J. T. Milliken bought the Golden Cycle mine he erected his own mill. From that day the trust began to lose money.——McGillvary and partners, lessees in the El Paso, have opened a shoot that averages $50 per ton without sorting.——Four carloads (30 tons each) of ore from the Cresson were shipped recently. The average value was about $1200 per ton. The Golden Cycle mill is treating this ore.——A 100-ton treatment-plant has been erected at the Jerry Johnson by F. T. Caley. He has a lease down to 650 ft. Below this the Cripple Creek Deep Leasing Co. has the ground. The shaft is down 925 ft. The output of the mine to date is approximately $1,750,000.

IDAHO

Bonneville County

Work has been resumed at the Carbon gold mine in the Mt. Pisgah district, 12 miles southwest of Soda Springs, on the Oregon Short Line. The main shaft is to be retimbered. A hydroelectric plant is proposed for Eagle creek, 2½ miles distant. About 160 hp. can be developed. A 10-stamp mill is ready for crushing. About 12,000 tons of $6.15 ore is opened. F. A. Putnam is in charge.

Shoshone County (Coeur d'Alene)

Dividends paid by Coeur d'Alene companies in April totaled $638,850.

Construction of the aerial tramway of the Interstate-Callahan company connecting the mill with the railway at Sunset station, began two weeks ago. Between 70 and 80 men are employed. It is anticipated that the line, about 10,500 ft. long, will be completed and ready to operate not later than May 15.——In the suit of the Stewart Mining Co. *v.* the Ontario Mining Co. and others over apex rights, the U. S. Supreme Court has decided in favor of the latter. This upholds decisions of the State District and Supreme Courts.——On May 4 the Bunker Hill & Sullivan company paid dividend No. 212. This amounted to $81,750. The total to date is $16,119,000.——An excellent contract has been made by the Success company for the sale of its lead-zinc-silver ores. There are 130 men employed at the mine and mill.——The Federal company's Frisco and Morning mines are to be further equipped and developed. A 2500-cu. ft. Ingersoll-Rand compressor has been ordered for the latter.

MONTANA

The revised itinerary of the U. S. Bureau of Mines Rescue Car No. 5 in this State is as follows: Stockett, May 2 to 8; Sand Coulee, 8 to 15; Belt, 16 to 22; Lehigh (mail address *via* Windham), 23 to 29; Roundup, May 30 to June 5; Klein, 6 to 12; Billings, 13 to 14; Bear Creek, 14 to 19; Washoe, 19 to 26; Red Lodge, June 27 to July 3; and Billings, July 3.

Granite County

Development of the phosphate deposits near Philipsburg is to be commenced by the Montana Phosphate Co. J. D. Fields is in charge of the organization. A U. S. Geological Survey bulletin just issued shows that the production of phosphate rock in the United States in 1914, as shown by the quantity marketed by States, was 2,734,043 long tons, valued at $9,608,041. Output in the preceding year amounted to 3,111,221 tons worth $11,796,231. The War has interfered with foreign business, hence the decrease. Florida yielded 2,138,891 tons; Tennessee, 483,203 tons; and South Carolina, 106,919 tons. Western States produced only 5030 tons.

Silverbow County

The large electric hoist at the North Butte mine has been tested. It is capable of raising 7 tons of ore per trip. From a depth of 4000 ft. it can haul 200 tons per hour. Drums are 12-ft. diameter. The steel rope is 1⅜-in. diameter.

The report of the Anaconda company for 1914 shows that the plant treated 3,748,726 tons of ore at Anaconda and 488,244 tons at Great Falls. Metal output was 223,720,292 lb. copper, 8,314,116 oz. silver, and 99,651 oz. gold. Some of this was from custom ore.

Open-cut mining has been resumed at the Bullwacker. The mill will not be operated. One hundred tons of ore per day is to be sent to the Pittsmont and Washoe smelters.

In the long suit of minority shareholders (Peter Geddes and others) in the Alice company *v.* the Anaconda company, the former was given a verdict on May 1 by Judge George M. Bourquin. Briefly, the dispute was one in which the minority holders wished to stop an executed sale of the Alice mine to the Anaconda. They consider the price too small. The decision ordered that a re-sale be made. If no better price is secured, the previous transaction remains undisturbed.

NEVADA

Clark County

'A Gold-Platinum-Palladium Lode in Southern Nevada' is the title of Bulletin 620-A, written by Adolph Knopf, issued by the U. S. Geological Survey. It may be obtained free from the Director of the Survey at Washington, D. C. The deposit consists of a mass of fine-grained quartz inclosed in dolomites of Carboniferous age. The precious metals are especially associated with a rare mineral that is known by the rather unwieldy name plumbojarosite, a hydrous sulphate of iron and lead. The mineral is locally known as greenish talc. This name accurately describes its main physical properties. Pockets of the pure mineral carry 100 oz. or more of platinum and palladium and several hundred ounces of gold to the ton. This richness points to a concentration of the precious metals in the oxidized ore by surface solutions, so that in depth the pockets of extremely high-grade ore, such as are now being extracted, will give place to ore of moderate grade.

Elko County

In a special copper edition of 44 pages, *The Contact Miner* describes the present condition of the Contact district and its possibilities. The area has been worked for over 40 years. Some promising properties are the Brooklyn, Contact Copper, Copper Shields, Delano, Carria, Nevada Copper, and others. Contact is 20 miles south of the Idaho line, on the Little Salmon river, which almost encircles the district. Flotation processes have proved successful on the ores produced.

Esmeralda County

The Atlanta shipped nine carloads of $20 ore to the Western sampler during April. Rise No. 1011-A is in $27 ore. Some contains copper. No. 1012-A is up over 65 ft. in $8 ore.——At 500 ft. in the Reorganized Booth, the drift is opening $10 ore.——The winze below 500 ft. in the Sandstorm-Kendall is to be sunk deeper.

The estimated production of the Goldfield Consolidated company for April is as follows: Ore mined, 30,822 tons; gross extraction, $317,000; operating expenses, $169,500; and net realization, $147,500.

Nye County

In the suit of the Jim Butler-Tonopah Mining Co. *v.* the West End Consolidated Mining Co., involving the ownership of ore in part of the latter's property, Judge Mark A. Averill, on April 30, decided in favor of the West End company. The case was one of extralateral rights, of great importance. Editorial reference to the dispute appears in this issue of the *Press*.

The pending suit of the Tonopah Mining Co. of Nevada *v.* the Tonopah Extension Mining Co. has been settled out of court by the directors in Philadelphia. A side-line agreement has been arranged. At 400 ft. in the Extension the west stope on the Egyptian vein is 20 ft. wide. On the 1260-ft. level the Murray vein has been cut. It is also 20 ft. wide. At 1170 ft. the shoot is 35 ft. wide. The weekly output is 1680 tons.

Eight mines at Tonopah produced 10,665 tons worth $217,930 during the last week of April.

Storey County

On May 3 the United Comstock Pumping Association had succeeded in lowering the water below the 2700-ft. level.

OREGON

Josephine County

(Special Correspondence.)—The mines of western and southern Josephine county, in and about the old mining town of Kerby, are more active this season than they have been for many years. The westward extension of the railroad from

Grant's Pass to Crescent City, California, has much to do with this awakening. A number of the larger properties are low-grade, and need adequate transportation. The assurance of this has stimulated mine-owners and mining companies to resume work on claims and properties that were practically abandoned. Copper, platinum, silver, iron, chrome, manganese, and limestone ores also occur in commercial quantities, and are being developed.——The new owners of the Takilma mines and smelter, Gunnell and Reddy, are preparing for the summer's work.——Prospectors are going forward up the Siskiyou trail from Holland, up around the old Briggs mine at an elevation of 4000 to 5000 ft.——Though there is considerable snow on the Siskiyous and the coast ranges, old

SOUTHWEST OREGON AND NORTHWEST CALIFORNIA. A NEW RAILROAD IS TO BE CONSTRUCTED FROM GRANTS PASS TO CRESCENT.

surface miners predict a shortage of water for placering this spring and early summer. The reason given for this is that the snow fell on dry ground. Mr. Wimer, manager of the Deep Gravel hydraulic mine, this being one of the most important in southern Josephine, states that his observations, covering many years in this district, lead him to believe the present season will be short, as the snow will melt without raising the streams, most of the water being absorbed. He is, however, making good use of the existing supply, and operating steadily.——The Logan and Simmons hydraulic placers have two to three giants in continual operation. The manager, John Logan, says this has been a fine season for these mines, and a number of very satisfactory clean-ups has already been made.——Among the quartz gold properties of this district that are making good showings with development done is the January First, on Sucker creek, owned by Harry Siskron. Ore is being packed out by burros and treated in a distant mill, and returns a profit.——The Little Gem mine, nearby, owned by D. K. Sutherland, is also opening satisfactorily.——One of the highest mines of the district is the Bird, at an elevation of 5300 ft., on Bollon creek. It is owned and being developed by Herz & Tibbits.

Philomath, April 28.

UTAH

The metallurgical treatment of the low-grade and complex ores of Utah is the subject of a preliminary report, 'Technical Paper 90' of the U. S. Bureau of Mines, by D. A. Lyon, R. H. Bradford, S. S. Arentz, O. C. Ralston, and C. L. Larson. It is issued jointly by the Bureau and the department of metallurgical research of the engineering station of the University of Utah. The paper consists of 38 pages, and should be procured by all mining men in the State. The discussions include cheaper treatment of silver ore, lack of zinc smelter in the State, the milling problem at Park City, low-grade ores of Tintic, characteristics of the ores of Utah, present processes, and possibilities of other methods.

Salt Lake County

The Arthur and Magna mills of the Utah Copper Co. are operating at full capacity. The payroll is now about $320,000 per month. In the suit of the company against the county for excessive taxation, the latter authorities had to pay $31,790. Two other cases are pending for nearly similar amounts.—— The Koehring cyanide process is being installed at the Wasatch Utah company's mine at the mouth of Little Cottonwood cañon.——In March the Utah Apex shipped and treated 3738 and 9890 tons of ore respectively. Operating profit was $10,920.

Utah County

To drain and afford easier development of the American Fork district mines, it is proposed to drive a 2000-ft. adit. Water has prevented shafts from being sunk below 100 feet.

WASHINGTON

Snohomish County

(Special Correspondence.)—The Eclipse Consolidated Mining & Investment Co., of Seattle, has a quicksilver mine in this county. Ore reserves are estimated at 78,125 tons. The average content is 2.25% mercury. The ore also contains a large value in gold and silver. One furnace is in operation. Others are to be built in May.

Seattle, April 27.

Stevens County

After a lapse of 15 years, 45 tons of silver-lead ore from the Bonanza mine, near Bossburg, has been sent to the Trail smelter. In the early days this property produced nearly $1,000,000.——The United Copper mine has shipped 2842 tons of ore this season to Trail. Twenty-five additional men are to be taken on. Fifty stamps are being added to the mill.

CANADA

British Columbia

A three years' lease on the Kootenai gold mine, near Nelson, has been taken by the General Mining & Milling Co. of Spokane, Washington. The price is about $85,000. A 20-stamp mill has been working for 18 years. It will be remodeled. The output to date is about $1,000,000. Twenty-three sets of lessees are working. A lower adit is to be driven. This company is to erect a mill on the Flying Dutchman, 15 miles north of Nelson. E. V. Boog is in charge.

The Rocher de Boule Copper Co., operating near Hazleton, has sent 900 tons of ore to the Granby smelter. The ore will average $50 per ton. The present output is between 100 and 125 tons per day. An aerial tramway, 3½ miles long, connects the mine with the Grand Trunk railroad. D. Williams is in charge.

Ontario

Diamond-drilling is being done at 300 ft. in the Vipond. A winze is being sunk from 300 to 400 ft. The mill yielded $77,000 in the first quarter of 1915.——In March the Hollinger mill treated 25,780 tons of ore averaging $11.53 per ton. Owing to power shortage, operations were curtailed somewhat.—— At the Cobalt Reduction Co.'s mill the new slime plant was started last week. It has a capacity of 170 tons per day.

KOREA

On May 6 the Oriental Consolidated Mining Co. paid dividend No. 29, of 50c. per share. On 429,390 shares issued this is equal to $214,695.

PERSONAL

C. S. Herzig is at New York.

Charles M. Rolker is at New York.

Walter Harvey Weed is here from Boston.

Howard F. Wiebum was in Oregon recently.

L. A. Smith is at Lebong Donok, in Sumatra.

D. M. Riordan is now residing in San Francisco.

W. R. Lewis has returned to London from Siberia.

W. B. Cogswell is here from Syracuse, New York.

W. W. Mein is at Oakland on a visit from New York.

Leon J. Pepperberg has gone to Texas and Oklahoma.

Scott Turner sails from New York for London on May 1.

H. C. Wilmot has gone to Oregon and Idaho on professional work.

G. E. Stephenson has gone from London to Western Australia.

Rensselaer H. Toll, of Denver, is at Angels Camp, California.

H. W. Faulkner, recently in Mexico, has been on a visit in England.

Herman A. Prosser now has his office at 120 Broadway, New York.

E. N. Skinner is now with Hayden, Stone & Co., at their New York office.

L. L. Moore is superintendent at the Gold Road mine, at Oatman, Arizona.

Wallace E. Pratt expects to return to the United States in July for a vacation.

J. H. Collbran passed through San Francisco this week on his way from Korea to New York.

M. S. Brandt is engineer to the Seneca Consolidated Gold mines in Plumas county, California.

H. C. Dudley, of Duluth, passed through San Francisco, going from Arizona to the Coeur d'Alene.

L. D. Ricketts and J. C. Greenway were at the Fairmont hotel during the week; they have returned to Warren, Arizona.

J. V. N. Dorr was in San Francisco this week and has returned to Denver, where he will remain for the rest of the month.

William F. Jahn, metallurgical engineer, from San Juancito, Honduras, is sojourning in San Francisco on his way to New York.

F. Sommer Schmidt has been appointed superintendent of the American Flag mine and consulting engineer to the Park City Milling Co., at Park City, Utah.

Frederic R. Weekes, for the past five years connected with the New York office of A. Chester Beatty, will continue his engineering practice at 71 Broadway, New York.

David W. Smyth, formerly floor-member of the firm of Thompson, Towle & Co., is now a member of the firm of Filor, Bullard & Smyth, the former firm having been dissolved.

H. A. Morrison, formerly shift-boss for the Globe Consolidated at Dedrick, California, has left for Aurora, Nevada, where he has accepted a position in the mill of the Aurora Consolidated.

Durward Copeland, Professor of Metallurgy and Ore Dressing in the Missouri School of Mines and Metallurgy, is at New York preparing for a trip to England, the Straits, and other tin-producing countries.

S. C. Thomson, formerly consulting mining engineer to S. Neumann & Co., and J. N. Bulkley, formerly consulting mechanical and electrical engineer to the General Mining & Finance Corporation, have opened joint offices at 120 Broadway, New York.

Lead Production in 1914

By C. E. Siebenthal.

(Advance statement, U. S. Geological Survey.)

World's Production of Lead

Short Tons

Country.	1911	1912	1913

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, May 6

Antimony	28	—28¾
Electrolytic copper	19¼	—19½
Pig lead	4.45	— 5.45
Quicksilver (flask)	$70.00	
Spelter	15	—15¼
Tin	45	—46½
Zinc-dust, 100-kg. zinc-lined cases	17	

On account of the rise in spelter, zinc-dust is higher. Carload lots are sold at 15c. per pound. Zinc sheets are also high.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, May 5.—Copper is easier, lead is dull; urgent demands for spelter have subsided.

On the following page of this issue appears the first of a weekly letter from New York covering the metal markets.

COPPER

Prices of electrolytic in New York, in cents per pound.

June	13.60	....	Dec.	12.75	....

Exports during the week ended April 17 totaled 10,098,634 lb., valued at $1,504,985. Of this, 5,702,566 lb. went to England, 2,298,396 lb. to France, 1,360,329 lb. to Italy, and 560,335 lb. to Russia by way of Siberia. Imports amounted to 9,645,745 lb. in ore and matte and 2,528,538 lb. in bars, etc.

March yields of Chino, Nevada Con., Ray, and Utah Copper were 1,416,087, 4,535,192, 5,632,168, and 10,203,882 lb. respectively. Calumet & Hecla has sold ahead of production 45,000,000 lb. at 15 to 20c. per pound.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date		Average week ending	
Apr. 29	50.62	Mch. 24	50.33
" 30	50.50	" 31	50.14
May 1	50.50	Apr. 7	50.04
" 2 Sunday		" 14	50.06

May	58.21	....	Nov.	49.12	....
June	56.43	....	Dec.	49.27	....

The silver market shows strength for a few days, then quotations fall. Evidently there is a lack of support, or too much is placed on the market for sale. On May 1 about 350,000 oz. left San Francisco for the Orient. Last week the Nipissing shipped 250,501 oz. to London via New York.

ANTIMONY

Little can be said of antimony so far as English brands are concerned. Their quotations throughout April were nominal at 32c. for Hallett's, and 35c. for Cookson's. All of the business was in Chinese metal, the prices of which ranged from 20 to 21c. England's reason for placing an embargo on the exportation of antimony is due in large part to its use as a hardener in shrapnel bullets. The shot which the shells scatter contains 10 to 12% of antimony.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date		Average week ending

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending

The American Zinc, Lead & Smelting Co. has sold to the General Electric Co. 150 tons of spelter at 17c. per pound for June and July. On May 1 zinc ore at Joplin was in good demand at $70 to $75 per ton, basis of 60% metal. Highest price paid was $78. Weekly production is about 5400 tons. Shipments are over 6000 tons. Stocks are therefore decreasing. The Picher Lead Co. has leased the Carlinville zinc smelter of 1536 retorts, at Carlinville, Illinois.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1914.	1915.		1914.	1915.
Jan.	37.85	34.40	July	31.60	....
Feb.	39.76	37.23	Aug.	50.20	....

May	33.29	....	Nov.	33.51	....
June	30.72	....	Dec.	33.60	....

On May 5 tin was dull at 39.50c. per pound.

ALUMINUM

Spot aluminum is nominal at 19 cents.

Eastern Metal Market

New York, April 30.

SUMMARY

The strength of copper is unimpaired. Tin is lower following larger arrivals. Lead is quiet at unchanged prices. Spelter is scarce and stronger. Chinese and Japanese antimony is stronger, while English brands continue nominal.

COPPER

In the past few days there has been a good business in both electrolytic and Lake copper, with the latter in greater demand. It is estimated that the domestic consumption for ordinary industrial purposes is about 60% of normal, which is something of an improvement. The urgent call, however, continues to be for metal to be used in the manufacture of munitions of war. Electrolytic is quoted today at 18.62½c., cash, New York, and prime Lake at 21c. cash. It remains true that the prices of choice brands of Lake are subject to private negotiation and at least 23c. is paid for some of them. More ordinary brands sell at 21 to 22c., and arsenical brands at 20c. or less. Producers of prime brands of Lake are sold up to August, and there is not much electrolytic to be had for early delivery.

Following the rising market, the American Smelting & Refining Co. announced the base price of hot-rolled sheet-copper in April as follows: April 8, 21c.; April 13, 21¼c.; April 14, 21½c.; April 17, 22c.; April 19, 22½c.; April 22, 23c.; and April 28, 24 cents per pound.

SPELTER

Large consumers of spelter in the manufacture of galvanized sheets are showing anxiety over the future supply of the metal. They do not want to commit themselves to forward deliveries of sheets unless they know that the necessary spelter will be forthcoming. Spot metal is quoted today at 14.50 to 15c., and only an occasional car can be found. Sales of prime Western have been made at 14c. for future delivery. Metal has been offered at 13.25c. to 13.50c. for June and July, and at 12.25c. for deliveries scattered through the remainder of the year. The ordinary differential between New York and St. Louis prices no longer exists. London has been much excited in the past few days. On April 28 it advanced £5 10s. to £64 10s., thereby breaking all records for sharp advances in the spelter market. Another effort to halt the market was made on the floor of the New York Metal Exchange on April 28, 100,000 lb. being offered for May delivery. It was sold in two lots of 50,000 lb. each, bids being accepted at 13.25c. and 13c. These prices are not taken, however, as being a true index of the open market. The interests that sold are the same as sought to bring the market down a few weeks ago, and with some success, although this time it was the metal and not a price which was offered. The chief demand continues to be for the choice grades used in the making of cartridge metal, and fancy prices are obtained. The base price of sheet zinc was announced on April 28 as 16c. f.o.b. smelter, an advance of ½c. per pound.

TIN

Activity of late has been almost entirely confined to futures, with the spot market nominal at declining prices. The quotation today was 39.50c., against 55c. April 14. The cause of the decline was the heavy arrivals, particularly from the Far East in the last few days of April. The steamer *Chinese Prince* arrived with 400 tons from Singapore, 125 tons from Penang, and 75 tons from Batavia and Hongkong. The *Shimosa* arrived with 550 tons from Singapore, 400 tons from Penang, and 25 tons from Hongkong; the *Dardanus*, with 575 tons from Batavia, while there also were fair arrivals from London and Liverpool. In the month 4310 tons arrived. Much of this tin will be applied against old contracts, and it is predicted that another scarcity will exist shortly. The quantity now afloat is 2200 tons, 725 tons of which is from Banca. The deliveries for the month were fair, amounting to 3200 tons, 1100 tons of which came to the East by way of Pacific ports. In stocks and landing April 30 was 3041 tons. The trade continues to be greatly hampered by the regulations and restrictions imposed by the British government. The Tin Committee of the New York Metal Exchange has been directed to continue its efforts to obtain a modification of England's requirements, and in the meantime sellers will not be liable on their contracts to deliver unless consumers supply the necessary agreements. It also was decided that sellers were not liable on April contracts if the necessary agreements were not received in time.

LEAD

The market is quiet. London quotations have been up and down alternately, though in quotations here there has been little change. The New York price is 4.20c. and that at St. Louis 4.10c., the latter being fixed by independent producers. The great war demand for copper and spelter does not seem to be shared by lead, much as the latter metal is associated with ammunition. A recent break in London is attributed to manipulation by interests who sought to buy to advantage, with a view of then letting the price rise again.

ANTIMONY

In the past few days the mere offering of antimony was sufficient to cause a scramble. Yesterday there was large buying of spot and future Chinese metal, and the market advanced to about 30c. per lb. It was quoted at 27 to 28c. theretofore. Cookson's is nominal at 35 to 36c., and Hallett's is unquotable. Future Chinese antimony has sold at 27 cents.

ALUMINUM

Prompt shipment metal, 98 to 99% pure, is quoted at 19.25 cents per pound.

EXPORTS OF METALS, APRIL 1 TO 30, 1915

Copper	15,472 tons	Spelter	4854 tons
Lead	5,963 "	Tin	74 "

Schools and Societies

The UNIVERSITY OF UTAH summer session of five weeks will commence on June 7. The faculty for 26 subjects will consist of 45 instructors.

The AMERICAN PETROLEUM SOCIETY will hold its annual meeting at San Francisco from October 25 to 30. Besides the reading and discussion of papers special excursions to the oilfields of California and Oklahoma are being arranged.

The St. Louis branch of the A. I. M. E. held its annual meeting, dinner, and excursion on May 1. W. L. Saunders and Bradley Stoughton were present, also H. W. Gepp, of Broken Hill, New South Wales. The new zinc smelter of the Granby company at East St. Louis was visited.

The department of Mining Engineering and Metallurgy of the MASSACHUSETTS INSTITUTE OF TECHNOLOGY has received through the courtesy of Charles Hayden, '90, a member of the Corporation, an interesting addition to its laboratory equipment. This is a complete working unit of the Janney oil-flotation apparatus. The machine is fitted with more than the usual adjustments for various ores. It has an electrical control to enable it to be worked at different speeds, also observation windows for observing the action.

Copper Production in 1914

By B. S. Butler

*The smelter production of primary copper in the United States in 1914 was 1,150,137,192 lb., compared with 1,224,484,098 lb. in 1913, a decrease of about 6.1 per cent.

The total value of the 1914 output, at an average price of 13.3c. per pound, is $152,968,246, against $189,795,035 in 1913.

In the following table the production for 1914 is apportioned to the states in which the copper was mined. The total is made up of fine copper contents of blister produced, and of the smelter output of ingot and anode copper from Michigan. The production of 1913 is given for comparison.

Production of Copper in the United States in 1913 and 1914

[Smelter output, in pounds fine.]

	1913	1914		1913	1914
Alaska	23,423,070	24,980,847	Pennsylvania	245,337	422,741
Arizona	404,278,809	382,444,922	Philippine Islands	22	
California	22,492,265	29,784,173	South Dakota	4,549	
Colorado	9,052,194	7,310,066	Tennessee	19,489,654	18,061,112
Idaho	8,711,490	5,875,205	Texas	39,008	34,272
Maryland		12,248	Utah	148,057,450	100,589,660
Michigan	155,718,286	158,009,748	Vermont	5,771	
Missouri	570,204	73,519	Virginia	46,961	17,753
Montana	285,719,918	230,805,845	Washington	732,742	683,602
Nevada	85,209,536	60,122,904	Wisconsin		10,098
New Mexico	50,196,881	64,204,703	Wyoming	362,235	17,082
North Carolina	180	19,712	Undistributed	40,803	55,381
Oklahoma	11				
Oregon	77,912	5,599		1,224,484,098	1,150,137,192

The total production of new refined copper in 1914 was 1,533,781,394 lb., a decrease of 81,286,388 lb. from the 1913 output.

The production of electrolytic, Lake, casting, and pig copper from primary sources and the production of secondary copper by the regular refining plants in 1913 and 1914, is shown in the following table:

Production of Primary and Secondary Copper by the Regular Refining Plants in 1913 and 1914

[In pounds.]

	1913		1914	
	Domestic.	Foreign.	Domestic.	Foreign.
Primary:				
Electrolytic	1,022,497,601	378,243,869	991,573,073	323,358,205
Lake	155,715,296		158,009,748	
Casting	22,606,040		21,506,325	
Pig	36,004,986		39,334,043	
Total primary	a 1,236,823,913	a 378,243,869	a 1,210,423,189	a 323,358,205
	1,615,067,782		1,533,781,394	
Secondary:				
Electrolytic	14,862,577		27,702,968	
Casting	22,360,182		4,224,052	
Total secondary	37,222,759		31,926,980	
Total output	1,652,290,541		1,565,708,374	

a The distribution of refined copper of domestic and foreign origin is only approximate, as an accurate separation at this stage of manufacture is not possible.

The figures for Lake copper include the Michigan copper that was electrolytically treated.

In addition to the secondary material treated by the regular refining companies, plants that treated secondary material exclusively produced a total of 224,000,000 lb. of copper as copper and in brass and other alloys of copper, making a total production of 256,000,000 lb. from secondary sources. Of this total at least 80,000,000 lb. was produced by re-melting clean scrap produced in the process of manufacture of copper and brass articles.

If the output of plants treating purely secondary material is added to the production of the regular refining companies, the contribution of domestic plants of the United States to the world's supply of copper for 1914 is found to be 1,790,000,000 pounds.

In addition to the output of metallic copper, the regular refining companies produced bluestone with a copper content of 8,602,861 pounds.

*Advance statement of U. S. Geological Survey.

Returns from all producing companies show that the following stocks of electrolytic, Lake, casting, and pig copper were on hand at the beginning and end of the year 1914:

Stocks of Refined Copper

	Pounds.
January 1, 1914	90,385,402
January 1, 1915	173,640,501
Increase during 1914	83,255,099

In addition to the stocks of refined copper, there were reported as at the smelters, in transit to the refineries, and at the refineries, blister copper and material in process of refining to the amount of 203,067,571 lb., on January 1, 1915, as compared with 247,789,811 lb. on January 1, 1914.

The apparent consumption of refined new copper in the United States in 1914 was about 711,268,000 lb. In 1913 it was about 812,268,000 lb. The method employed in determining the quantity of copper retained for domestic consumption is shown in the following table, which does not include stocks of copper held by consumers:

Apparent Domestic Consumption of Refined New Copper in 1912, 1913, and 1914

[In pounds.]

	1912	1913	1914
Total refinery output of new copper	1,568,104,478	1,615,067,782	1,533,781,394
Stocks at beginning of year	88,372,105	105,497,653	90,385,402
Total available supply	1,656,476,673	1,720,565,435	1,624,166,796
Refined copper exported	a 775,000,658	a 817,911,424	a 748,902,137
Stocks at end of year	105,497,653	90,385,402	173,640,501
Total withdrawn from supply	880,498,311	908,296,826	922,542,638
Apparent consumption	775,978,332	812,268,689	711,624,158

a Exports of pigs, ingots, and bars reported by the Bureau of Foreign and Domestic Commerce.

If to the 711,624,158 lb. of new refined copper is added the 256,000,000 lb. of secondary copper and copper in alloys produced during the year, it is found that a total of about 968,000,000 lb. of new and old copper was available for domestic consumption.

Copper Selling Prices in 1914

The following table from *The American Metal Market* shows the averages received by the selling agencies in 1914. Phelps, Dodge & Co. received the highest.

	Sold, pounds.	Prices, cents per lb.
Phelps, Dodge & Co.:		
Copper Queen, Detroit, Moctezuma	141,662,324	13.72
Calumet & Arizona	52,667,920	13.72
United Metals:		
Utah Consolidated	7,584,391	13.57
American Smelting & Refining Co.:		
Ray Consolidated	57,004,281	13.41
Tennessee Copper	12,871,113	13.706
American Metal Co.:		
Old Dominion	23,903,958	13.71
East Butte	8,175,579	13.5685
A. Lewisohn & Sons:		
Miami	32,879,447	13.3488
Shattuck-Arizona	10,846,918	14.1293
Calumet & Hecla (Lake):		
Tamarack	1,074,808	12.80
Isle Royale	6,601,235	13.16
Ahmeek	13,634,000	13.08
L. Vogelstein & Co.:		
United States Smelting	17,946,659	13.404
United Verde	32,449,116	13.553
Direct:		
Mohawk (Lake)	11,094,859	12.47
Quincy (Lake)	15,356,380	13.3

New Machines and Devices

Information based on letters and catalogues from manufacturers.

A New Cupel

The Joseph Dixon Crucible Co., Jersey City, New Jersey, has put on the market what it calls 'Dixon's wonder cupels.' These are made in three sizes, $1\frac{1}{4}$, $1\frac{1}{2}$, and $1\frac{3}{4}$-in. diameter. It is claimed that these cupels will be a veritable joy to refiners and assayers. Absorption of silver is much less than with cupels made from bone-ash, when used under similar condition. They are made of such strength that they will not break in handling. The cupels are packed in lots of 100, 500, and 1000.

A DIXON WONDER CUPEL.

On account of the War it has been a question for some time if it would be possible for foreign firms to supply United States laboratories and refiners with clay crucibles. The Joseph Dixon Crucible Co. has now a fairly complete line of assay crucibles, scorifiers, and goods of a like nature. So far the sale has not been of so great volume that the company has been able to compete in price with foreign makers. As scarcity increases, and larger orders are secured, there is little doubt but that as low, or possibly lower, prices can be made than imported goods of a similar nature now command.

Power Transmission at the Exposition

An instructive working exhibit arranged by the Dodge Manufacturing Co., of Mishawaka, Indiana, is open for inspection at the Palace of Machinery at the Exposition in San Francisco. Two forms of the Dodge 'American' system for transmission of power by manila rope are shown. The first is a direct drive from a motor to an intermediate shaft, horizontally. The second drives from this intermediate shaft vertically over idlers, thence horizontally to other idlers, thence down to the horizontal shaft. This shaft is mounted on floor-stands fitted with a friction-clutch that connects with an extension shaft that has a flexible-coupling and two pulleys driving a group of various types of conveyors. These conveyors consist of an oscillating-conveyor, a Zimmer shaking-conveyor, and three ordinary conveyor-belts. The first two mentioned are new for this particular service. This conveyor system, as shown, is attracting considerable attention among the mining men for handling and screening ore.

Among other interesting features in the exhibit is the 500-lb. flywheel running about 100 r.p.m., supported by the Dodge ring-oiling babbitted bearings, operated by a black linen thread (one strand) running over its periphery.

The method of lubricating what is known as the capillary bearing is shown. This is produced by a slotted block of wood placed in an opening in the bottom of the bearing, reaching down into a reservoir of oil underneath the shaft, held against the shaft by a coil-spring. The oil works through the slots up to the shaft by capillary attraction.

Two forms of friction-clutches, the Dodge split and the Dodge safety, are shown. The Dodge flexible coupling is another new feature. It consists of two flanges and a series of elliptical springs so arranged as to give freedom and flexibility to the coupling, even though the shaft may be out of line. This coupling is distinguished by not having any sliding or moving parts, the springs being held rigidly in place. There is also displayed Dodge wood split-pulleys, with bushing system; iron-spider, wood-rim pulleys, solid or split; standard iron split-pulleys; pillow-blocks for all services; line shaft-hangers; floor-stands; demonstration of methods of lubricating shaft bearings; demonstration of additional power required to turn shaft when out of line; example of action of capillary attraction feeding oil to shaft; collection of photographs illustrating process of construction; samples of Dodge 'Firmus' rope for power transmission; and samples of a long-fibre manila used in making 'Firmus' rope.

Metal Hose at the Exposition

A simple yet attractive exhibit in the Palace of Machinery is that of the Pennsylvania Flexible Metallic Tubing Co., of Philadelphia, Pa. It consists of copper and steel flexible tubing from $\frac{1}{8}$ to 8-in. diameter. Also connections. The pipe is suitable for liquid or gas. Three arches of 6-in. hose comprise the entrance to the booth. This tubing is used considerably at mines. At Panama over 200,000 ft. was employed. Severe tests were given. The company also shows an automatic barrel-filler. This cuts off the flow when the receptacle being filled has sufficient in it.

Manufacture of Spiral-Riveted Pipe

Spiral-riveted pipe has been in use for many years. Engineers and users of this class of pipe are familiar with its construction and the merits claimed for it over other types. In its manufacture, a strip of sheet-steel is wound into helical shape, with one edge overlapping the other for riveting the seam. In the process used by the American Spiral Pipe Co., of Chicago, the sheet is drawn and formed in such a manner that there is obtained a metal-to-metal contact in the spiral seam, stretching the steel on the outer lap slightly offset, in order that the pipe may be more nearly smooth on the inside. The riveting is done cold by compression, or squeezing under enormous pressure, not by percussion or hammering. This insures complete filling of the rivet-holes with slight countersink. The pipe comes from the machines in a continuous piece, and is cut to any desired length.

SPIRAL-RIVETED PIPE IN THE KLONDIKE. THAT USED BY THE YUKON GOLD CO. IS FROM 10 TO 42-IN. DIAMETER, OVER 30,000 FT. LONG, WITH A MAXIMUM HEAD OF 530 FEET.

Due to the mechanical construction of the pipe, the seam is the strongest part. This has been proved by hydraulic

tests for bursting pressure. This type of pipe has found a wide use in mining and the allied industries, where it has been profitably employed in connection with hydraulic power-plants also in hydraulic-mining operations.

The accompanying picture shows spiral-pipe with monitor connection as used at the Yukon Gold Co.'s property in the Klondike. At this particular installation there is between six and seven miles of spiral-riveted pipe, from 10 to 42-in. diameter. It is used for handling a head of water of 530 feet.

In the fourth edition of Catalogue No. 5, consisting of 80 pages, with illustrations, the AMERICAN SPIRAL PIPE WORKS, of Chicago, describes its products. This is an interesting publication. Besides showing the pipes and special fittings made, there are pictures of installations at the Homestake Mining, Yukon Gold, Henderson Light & Power, Sao Paulo, Brazil; Gotok Mining, Dutch East Indies; Incaoro Mines, Bolivia; Johnstown Water Co., Pennsylvania; Newhouse Mines, Utah; Ford Motor Co., and other mining and water companies.

Commercial Paragraphs

The April issue of the *Magazine* of the E. I. DU PONT DE NEMOURS POWDER Co., Wilmington, Delaware, contains some interesting notes on blasting for road construction, storing and thawing explosives, tamping and stemming, and electric blasting in coal mines.

The Isbell concentrator is the subject of Bulletin 1072 of the DENVER ENGINEERING WORKS Co., Colorado. Construction, operation, and points of superiority claimed are described. The table will treat feed containing from 6-mesh to slime, without previous sizing.

The sale of Nuttall gears, pinions, and trolleys, manufactured by the R. D. Nuttall Co., Pittsburgh, for the electric railway, mining, and industrial fields in the Chicago territory, has been transferred to the WESTINGHOUSE ELECTRIC & MFG. Co., 39 South La Salle street, Chicago.

In the annual report of the Inspiration Consolidated Copper Co., Arizona, the general manager, C. E. Mills, states that in the reduction of 14,000 tons of ore per day to 48 mesh MARCY ball-mills will be used. They will be fed with 1½-in. ore from the SYMONS disc-crushers.

The Sprague Electric Works of the GENERAL ELECTRIC Co. has issued two booklets on electric fans. These are for desks or ceilings, of all sizes, and are made for direct or alternating current. Prices are also given. The firm also publishes a folder on the 'Greenfielduct, the Pipe of Quality.'

In Catalogue U, the BROWN HOISTING MACHINERY Co., Cleveland, Ohio, describes its Brownhoist transfer-cars and larries. Cars of 60-ton capacity are used at the Bethlehem Steel, Dominion Iron, and other large companies' plants. The reciprocating gates used on bins give good service.

Electrically-driven centrifugal pumps are now unwatering the Penrose shaft of the Down Town Pumping Co.'s area at Leadville, Colorado. They were made by the PROVIDENCE ENGINEERING WORKS, Providence, Rhode Island. The drainage of this ground is expected to result in considerable ore being opened.

Three 30-in. LAGONDA multiple strainers are being added to the present equipment of the Duquesne Light Co., Pittsburgh, Pennsylvania. With this latest installation the plant will have a total of eight 30-in. Lagonda strainers. This company has also one 6, one 12, and one 14-in. strainer installed in its Rankin station.

Leschen's Hercules for April contains interesting illustrated notes on construction where its wire-rope is used, namely, at a gravel plant in Illinois, at the Alaska Gastineau mill at Juneau, Capitol of Utah at Salt Lake City, and constructing a 105,000-hp. hydro-electric plant in Alabama. Care of hoisting cables is discussed.

Type 'A' transformers of large capacities, type 'M' demand indicators (maxicators), type 'P' demand indicators (printometers), and commutating pole direct-current crane and hoist motor CO-1800 line are illustrated and described in *Bulletins* 45,201, 46,100, 46,101, and 48,100 of the Fort Wayne Electric Works of the GENERAL ELECTRIC Co. An index to active bulletins published is also to hand.

Oil-engines of the Diesel type are discussed in Bulletin 1532 of the ALLIS-CHALMERS MANUFACTURING Co., Milwaukee, Wisconsin. This particular design is of the horizontal type, operating on the true Diesel principle, using the open fuel-injection nozzle. The bulletin briefly describes the construction, governing, oils, cycle of operation, and shows indicator-cards of an engine using 12°B. Mexican crude oil.

For the power-plant of the San Luis Mining Co., Sinaloa, Mexico, sectionalized Pelton-Francis turbines and accessories were made by the PELTON WATER WHEEL Co., of San Francisco. Some parts were carried by mules, others by Indians. Three wheels will soon be in operation. Water for the plant comes from the Piaxela river. About 100 miles from Mazatlan the stream makes a wide ox-bow curve, flowing several miles through rock, then returning at one point within a few yards of its previous bed. Here the hydro-electric plant was built. Sectionalized wheels were described in the *Press* of February 6.

The report of the INGERSOLL-RAND Co. for 1914 shows that the net revenue was $1,967,723, only $50,177 less than in 1913. After paying interest, dividend, depreciation, etc., the surplus was $973,586. Two bulletins have recently been published by this firm. Form 3015 deals with portable air-compressors. These machines have been devised especially for contractors, miners, factories, and others using air-driven tools on work of a temporary nature. Form 4032 discusses the Jackhamer mounting, type JM-6. The mounting is for this machine, with or without water-feed, for flat, shallow holes in metal mines, and for use in coal mines.

Elevating, conveying, crushing, screening, power-transmission machinery for the mill, factory, and mine. 6 by 9 in., 384 pages. Illustrated. General catalogue No. 83. The JEFFREY MANUFACTURING Co., Columbus, Ohio, 1915. Among the 64 different industries using Jeffrey machinery are cement mills, chemical works, clay works, coal mines and accessory plants, dredges, filtration plants, foundries, irrigation works, mine ventilation systems, metal mines, power-houses, quarries, sand and gravel plants, and smelters. A great variety of screening and conveying systems is manufactured by this firm. Transmission of power by chains is gaining in favor. They are described in this publication in detail. A line of rope pulleys and friction-clutches is also made. Prices are given with each product mentioned.

An improved combination ore-feeder and ore-bin gate is being made by the E. H. MOYLE ENGINEERING & EQUIPMENT Co. of Los Angeles. In this patent the table of the feeder constitutes, and is, the bottom of the orebin. This arrangement is claimed to eliminate the old-style vertical ore-bin gate at the front of the bin, that was previously used to regulate the ore to the old-style feeder, located at the back of the mortar. This caused a considerable amount of trouble by reason of the clogging up of the vertical ore-bin gate.

Patents 1,121,117 and 1,121,118 have been granted to E. H. Moyle for a mortar for stamp-mills. They relate to improvements in mortars. The main object is to provide a means for distributing the ore to be crushed to each stamp separately, and to distribute the ore by circular means around the stamps. Other improvements claimed are in connection with access to stamps, prevention of cupping in dies, larger screen area, and increased capacity.

Mining and Scientific Press

Edited by T. A. RICKARD

Volume 110 | SAN FRANCISCO, MAY 15, 1915 | Number 20

TONOPAH is one of Nevada's famous mining districts. Just now it attracts attention on account of new discoveries and apex litigation. We publish articles on these allied phases of mining activity. Next week Goldfield will be our subject.

TONOPAH, NEVADA

WITH this issue also we begin a series of technical reminiscences by Dr. Albert R. Ledoux, of New York, ex-President of the American Institute of Mining Engineers. These will be found interesting and instructive, especially to the younger members of the profession.

See those Channels

The
Channeled Linoleum Top
of the
Card Concentrator

is indestructible. The superiority of channels over riffles has been proven by thousands of assays taken in competitive tests, resulting in every case in the installation of Card Tables

All patents valid and in force. Absolutely no litigation.

STOPING METHODS AT THE NEVADA WONDER MINE.
By Thomas M. Smither 757
Waste-filling is employed. The waste material for filling is mined from the walls of the stopes through inclined rises. The chutes and manways are timbered, using a minimum amount of timber. The disadvantages are that low-grade material must be left, and shoveling is required.

ASSAY OF CYANIDE SOLUTIONS.
By C. E. Roadhouse 760
The methods to be used in an assay-office depend not only on the results desired, but also on the arranging of the work so that can be performed with a minimum of effort. The method described gives satisfactory results, requires little manipulation and almost no watching during operation.

TECHNICAL REMINISCENCES—I.
By Albert R. Ledoux 761
The first of a series of reminiscences by an engineer whose work has brought him into contact with men of various types in many different parts of the world.

APEX LITIGATION. JIM BUTLER *v.* WEST END.
By H. V. Winchell 763
The decision handed down in this case establishes the two new points that a vein may have an apex within a claim even if it does not come to the surface, and that from an apex which resembles the crest of an anticline extra-lateral rights may be claimed along both limbs of the anticline. This further complicates the already hopelessly involved apex law.

EMPIRE DRILLS DREDGES EMPIRE

Placer Mining is a Sound and Profitable Business

Provided it is entered upon with the same good judgment that men apply to other business enterprises. And nothing has contributed so largely to place placer mining on a sound basis as the **"Empire"** Prospecting Drill, which eliminates every hazard from the operations and which gives absolute protection against unwise investment. If a property is barren, an **"Empire"** reveals the fact. If the values are there, an **"Empire"** not only shows them but shows how much, with an accuracy in no other way to be attained.

Let us send you the **"Empire"** Catalogs—a guide to good business in placer mining.

We also design and build a complete line of placer mining equipment, including **"Empire"** Gold Dredges, Hydraulic or Bucket Gravel Elevators, High Carbon Steel Sluices and Riffles, Hydraulic Pipe Lines, Giants, etc. We design and build to suit your conditions.

EDITORIAL

T. A. RICKARD - - - - Editor THOMAS T. READ - Associate Editor

MINING in the North is favored this year by an early break in the ice on the Yukon. The first steamer left Lake Lebarge for Dawson on May 5.

TRADE between Pacific ports, notably Seattle and the Orient, is breaking the record. The Great Northern Steamship Company has added Vladivostok to its ports of call. Mining engineers going to Siberia should note this fact.

PREPARATIONS are well under way for the use of flotation at Cananea, both for the treatment of current tailing and that which has been stored from previous operations. A machine devised for the purpose by Mr. David Cole will be used.

AMONG the survivors from the *Lusitania* disaster was Mr. Scott Turner, who at one time was on the staff of this paper and since then has made an honorable reputation for himself in a wider field. With his many friends we rejoice in his escape.

IN this issue we publish the first of a series of articles by Mr. Albert R. Ledoux, embodying technical reminiscences of a most interesting character. These were prepared for publication on our urgent solicitation, and will, we feel sure, be widely appreciated. Dr. Ledoux, as he is usually known in the profession, received his degrees of A.M. and Ph.D. from the University of Berlin, having previously spent three years in the Columbia School of Mines. He started business at New York in 1880 and since that time he has had a wide range of successful practice, as is well indicated in the articles we are fortunate in being able to publish.

WITH deep regret we record the death of Franklin Guiterman, on May 10, at New York. During recent years he was prominently associated with the Guggenheim mining and smelting enterprises, more particularly the New River coal company, in West Virginia. Before the big smelter consolidation was made by the Guggenheims, he was manager of the Durango plant in Colorado, and still earlier he was secretary of a clearing-house established at Denver for the distribution of the regional ore-supply. In this work he showed exceptional ability and tact, as he had previously as secretary of the Colorado Scientific Society. A graduate of Freiberg and a man of pronounced intellectual activity, Franklin Guiterman was a capable metallurgist, a sagacious man of business, and a good citizen.

MEXICAN MINERAL production figures have been almost impossible to secure of late. A supplement to *Commerce Reports* for April 30 contains interesting reviews of several states during the year 1914, as supplied by the respective United States Consuls. The declared exports of minerals were as follows, compared with those for 1913, the latter being in parentheses: Chihuahua—crude metals and ores, $3,661,820 ($4,390,-885); actual production, copper, 1,484,622 lb. (2,365,-056 lb.); gold, 10,998 oz. (13,127 oz.); lead, 24,040,508 lb. (33,985,575 lb.); silver, 5,052,439 oz. (5,490,594 oz.); and zinc (estimated), 107,977 lb. (8134 lb.) Aguascalientes—copper bullion, $1,399,873 ($8,816,376); and lead bullion, $189,177 ($938,051). Durango—gold, $36,-372 ($104,176); silver, $182,958 ($622,585); lead, $64,-794 ($181,634); and copper, $40,277 ($470,196). San Luis Potosi—bullion, $189,429 ($1,109,191). Tamaulipas—crude oil, $6,180,909 ($7,130,632). Nueva Leon—ore, $68,337 ($111,618); and bullion, $1,846,143 ($5,-210,835). Sinaloa—Silver and gold bullion, $584,687 ($2,502,430). These figures show exactly the result of the disturbed state of the Republic. Credits have been completely disorganized. Large producers will not resume operations until conditions become more stable. The supply of labor is insufficient and precarious. Supplies are difficult to transport to the mines, even when they are landed at ports. Currency is continually fluctuating and depreciating. Coke, cyanide, and dynamite have been confiscated. Retrenchment and uncertainty have prevailed in all lines of industrial enterprise or commercial activity. Railroad traffic has been hampered greatly. Such are the opinions voiced by the Consuls. Nevertheless, it is remarkable with what

tenacity operators cling to their mines and how they manage, despite misrule, to produce so large a volume of metallic products.

The Lusitania

The tragic end of this great steamship has caused a wave of emotion round the world. We shall not dwell on the political aspect of the event. To engineers the sinking of the ship appeals, among other reasons, as the destruction of one of the greatest feats of engineering, for the *Lusitania* in her hull, her machinery, and her internal arrangements as an ocean carrier was one of the proudest works of man. As a favorite among the vessels facilitating the crossing from New York to Liverpool, she was well known to a great number of mining engineers and metallurgists in every corner of the earth, and, as such, she with her officers, particularly the kind and genial purser, J. A. McCubbin, had won a special place in the regard of our nomadic profession. Fortunately on her last voyage she carried an unusually small quota of those engaged in metal mining, the larger portion of the business men aboard coming from among those dealing in war supplies and otherwise participating in the more deadly business to which millions of thinking men are now devoted. The news of the disaster had an effect recalling vividly the loss of the *Titanic*, but in this case the tragedy of the sea gained in horror from the fact that it was the deliberate action of man, not the accidental interference of Nature. For that reason to most of us the loss of life loomed larger than a ten-fold bigger casualty on the battlefield. It will sear the minds of even those that look on the European conflict as a cinema show, and it cannot fail to impress the wide world with the brutality of the destructive forces that have been let loose by the incidence of war.

Tonopah

In our last issue we referred to the outside activities of several of the leading companies in this famous silver-mining district of Nevada. From these it might almost be inferred that the district was decadent. Such an inference would be unjustifiable. True, the reckless days of bonanza discovery are largely past, but a large measure of progressive and expansive development continues. In the older part of the district—the portion identified with the early developments on Mizpah hill, at the foot of Mt. Oddie—the ore outcropped in vein-fractures traversing trachyte; the principal veins, the Mizpah and Valley View, being cut-off at a depth of 600 feet by an intrusion of rhyolite, accompanied by faulting. The Tonopah claim itself never yielded any ore below the 6th level, although numerous drill-holes were sunk 1500 to 2000 feet deeper. The premier company of the district is now gleaning from old workings. But in the two western claims, the Red Plume and Sand Grass, between the Tonopah Extension and the Midway properties, the work of development is proceeding on veins that show no bottoming of the ore. Elsewhere in the district the orebodies make no showing on the present surface, or, to use the terms of a much-abused law, they have no "top or apex" into the daylight of today. Fortunately, superficial prominence affords no measure of the persistence of ore at Tonopah, for the veins that outcropped were of brief continuity as compared with the lodes uncovered under the eruptive flows that cover the surface of a geologic yesterday. Under a cap of andesite the miner found lodes that not only followed the contact between the earlier and later eruptives, but vein-fractures and lode-channels that transgressed many of them. Despite a geologic structure that was complicated further by faulting of a manifold character, the miner, aided by the geologist, was enabled to trace the ore-bearing fractures and channels to a horizon far below that reached by the short-lived veins that had first invited exploitation. At the present time important orebodies have been uncovered in systems of fracture both in the trachyte and along its contact with rhyolite and breccia, and these orebodies are being followed westward under the flat that extends at the foot of Mt. Oddie. The rock encasing these new discoveries is later than the dislocation that interrupted the veins of the eastern area, hence they have escaped the geologic amputation associated with the intrusion of the rhyolite, more particularly. Recent developments westward, as we have stated, are encouraging, especially in the workings from the Murray shaft of the Tonopah Extension mine; also in the Tonopah Merger shaft northward. It is rumored that the West Tonopah is to be re-opened, while still farther west a new head-frame indicates the resumption of work at the Bonanza, on the strength of an important find in the Monarch Pittsburg, where a wide lode traversed by rich stringers was uncovered last February. By a joint agreement made between the owners of adjoining properties, the pumping in this territory is being done through the Victor shaft, so that the burden of unwatering and drainage is being performed systematically. All this is of good augury. Another cheerful note is furnished by the North Star mine, on the southwest slope of Mt. Oddie, where the lowest level, at 1250 feet, has found an orebody in a down-thrown block of trachyte. Apart from this peculiarity, the ore is remarkable locally on account of the increased proportion of gold. At Tonopah the average ratio of silver to gold quantitatively is 100:1; in this North Star orebody the ratio is about 12:1. Ore assaying $35 to $40 contains 1.35 to 1.5 oz. gold with 9 to 15 oz. silver per ton. The exploratory work at this place is meagre as yet, but it is highly promising and it is peculiarly interesting as indicating an increased proportion of the more valuable metal. As against these promising features there comes the threat of apex legislation, like a Banquo's ghost at the feast of the mining operators. The Jim Butler *v.* West End suit, just decided in the lower court, suggests the uncertainties of litigation, and we do not hesitate to express the hope that other disputants will be warned by it from going to law. It is no secret that the Jim Butler owners

were offered $125,000 and 'fifty-fifty,' that is, one half of the proceeds from ore below the disputed line; it being further suggested that the Jim Butler company should mine the ore while the West End people were to mill it. The ore in dispute was supposed to be worth $1,000,000. The Jim Butler company disdained the compromise outlined above and went to court, losing the first round of the contest. Meanwhile, with a good sense highly to be recommended, the Tonopah and Tonopah Extension companies have settled another apex quarrel, and we hope that this example may be followed. In a district where a real apex or outcrop is rare, it is unwise to make an appeal to the blind lady with the scales. For example, in one locality three separate veins unite in depth to form a lower contact. Which of these three veins is to give the apex right to that contact? And if not one of these three veins reaches the present surface, is the right of apex to be granted to one of them or all of them? Manifestly it will be more profitable to be a lawyer than a miner at Tonopah unless the good sense of the community exerts a restraining influence on litigious mine-owners. If the new discoveries of ore are to stimulate any measure of real prosperity in the district, it will be necessary to make such reasonable compromise as may ensure the spending of money in exploratory work underground, not in punitive expeditions in the courts. Given such a policy, we expect to see a healthy expansion of productive activity at Tonopah.

The Search for Platinum

Platinum ranks as one of the precious metals because of its value, approximately double that of gold. It also qualifies as belonging to the first rank of the so-called 'noble' metals, since it resists attack by both acids and alkalies; but according to use it might well be regarded as one of the necessary metals of industry, since its applications are almost entirely those of every-day work, its employment in the fabrication of jewelry being a recent fact that happily has attained no great vogue. Because of its freedom from attack by chemical reagents this metal has become essential to chemical research and engineering and no chemist ever has more platinum ware than he thinks he needs. As already indicated, the demand is persistent and strong, while the supply is limited. The mode of occurrence of platinum is essentially the same as that of placer gold, with which it is, indeed, found widely distributed in small amount. Some years ago there was much excitement throughout the United States over the discovery of the presence of small quantities of platinum in gold-bearing sand in many localities. The prospector was quickly disillusioned, however, for it was soon proved that the amount present was so small and the cost of recovering it so great that the sand could not be exploited at a profit. Fortunately for the chemist, however, platinum is found in large amounts in placer deposits in the Southern Ural mountains of Russia. There in the Perm, Tcherdinsk, South Ekaterinburg, and north and south Verchotur districts some 275,000 ounces of platinum is secured annually, about half of it by dredging and the remainder by ordinary washing operations. The Choco district of Colombia produces about 12,000 ounces per annum, also from placer deposits. The yield of the rest of the world is almost negligible, the production of all sources combined in the United States being only about 1000 ounces; one-half from placer operations and the remainder from the refining of copper and gold bullion. Russia is thus in the enviable position of controlling the world's supply of platinum, a situation that consumers do not regard with equanimity, since it would be perfectly feasible for the Government of that country to place an export-tax on platinum and make the foreign consumer pay it. Indeed, simply as a result of trade conditions, the selling price of platinum has doubled in the past decade. The search for platinum has, therefore, not only the stimulus of the high price of the metal but the added incentive of the desirability of finding domestic sources of supply.

The common practice of the gold miner after finding placer deposits is to hunt for the 'mother lode' from which they were derived. In the case of gold such search is not infrequently successful, but in the case of platinum deposits it has been uniformly unsuccessful. Until recently only in two cases has platinum been found in veins of any importance, in both instances associated with copper. The nickel-copper ores of the Sudbury district in Canada contain an appreciable amount of platinum in the form of the mineral sperrylite, the arsenide. About fifteen years ago sperrylite was also discovered in the copper ores of the Rambler mine, a short distance southwest of Laramie, Wyoming. This attracted much attention, but the deposit proved small in extent and the mine was quickly exhausted. This served to subdue the hopes of those who had seen in the finding of this deposit the possibility of discovering other lodes containing a recoverable amount of platinum, and though many copper mines have been developed since that time, in none of them has platinum been detected.

Recently a fresh field for the discovery of lode-platinum has been afforded by a find of that metal in a new association in the Boss Springs district of southern Nevada. This deposit consists of a mass of fine-grained quartz enclosed in Carboniferous dolomite. The platinum occurs associated with plumbo-jarosite, a hydrous sulphate of iron and lead, in notable amount, pockets of the pure mineral carrying as much as 100 ounces of platinum and palladium per ton. Statements as to the geology of the deposit are authentic, since it has been examined by Mr. Adolph Knopf for the United States Geological Survey. The vital question is whether the ore will prove to be non-persistent, as in the case of the Rambler mine, or whether masses of large size can be uncovered. If so, then the search for similar deposits in this and other districts will be much accelerated. This discovery serves to illustrate the fact that it is not safe to generalize too much regarding mineral associations. Platinum was not known to occur in lead deposits in

dolomite, and most geologists would have considered them an unlikely place for search until the find in Nevada put a new face on the matter.

An addition to the present domestic sources of platinum has also recently been made. The use of jigs on dredges to recover gold lost on the tables was described in our issue of November 28, 1914. It is proposed to use the jigs on the dredges of the Natomas company, recovering the gold from the jig-concentrate by grinding in Hardinge mills. The concentrate contains about $2 worth of gold per ton, and Mr. Charles Janin has recently made the important discovery that platinum, with its allied and equally valuable metals, is present. It is not yet certain whether this can be recovered cheaply, but if it proves practicable the platinum output of the United States will be nearly doubled thereby.

Industrial Journalism

On another page we publish a portion of an address on this subject delivered recently by Mr. Horace M. Swetland. We owe an apology to Mr. Swetland for giving so small a part of his address, which should be read in its entirety in order to be properly appreciated. While the subject is only related indirectly to the technology of mining, it interests us keenly. Industrial journalism has developed into a great institution, aiding and stimulating the application of science and system to the production and sale of manufactures. In America, more than anywhere else, this form of journalism has been one of the most serious and successful phases of press activity. Every division of industry has one or more periodicals devoted to the interests of those engaged in it; indeed, the term 'class journalism' is often used as a synonym, suggesting specialization in behalf of particular departments of industrial activity. Mr. Swetland himself mentions, as examples, several publications that are notable exponents of the textile trade, and we may add that he himself is the protagonist of the automobile business. At one time he was the publisher of our immediate contemporary and competitor at New York, so that he has an understanding of another branch of journalism, for we differentiate between the industrial and the technical phases of journalism. The latter may be included within the former, but it is, or should be, distinct from it. The distinction is not always visible to the unaided eye. What industrial journalism aims to be is told explicity by Mr. Swetland: its purpose is to serve the manufacturer and those supplying the raw material for manufacture. It holds out both hands frankly in solicitation for advertising patronage; to it the editor is a necessary evil; the business manager is the centre of productive activity. In short, the business of publishing such papers is frankly commercial, and they succeed exactly as they fulfil their function. "The constituent of the industrial press does not buy his paper to be entertained." He asks only that it shall be "of service to him in his business." He regards it merely as a commercial mentor and "leaves the problem of making the paper to the publisher," not the editor, who receives his orders from the controlling capitalist, who, in turn, goes in and out of the business as he sees chances to make money therefrom. There is no waste of sentiment and no continuity of tradition. The sole aim is to produce an effective device for merchandising by means of advertising. We trust that this description will not seem unkind just because it is plain. The work done by this branch of journalism is tremendously useful, and even if it is wanting in any lofty ideal, it is safe to say that it stands on a higher level than most of the daily press. We wonder whether Mr. Swetland and the other speculative publishers in New York will concede that technical journalism aims, even if it fails, to operate on a different basis? The technical periodical looks for readers, and all the support thereby implied, in a profession, not a trade. What is the difference? Well, the member of a profession does his work for the love of it, for the sake of doing it well, and in order to win an honorable livelihood; a tradesman does his work merely as a means of making money. A surgeon and a plumber are alike in some respects, but different in others; a society of mining and metallurgical engineers resembles an organization of plumbers, with a difference. How great that difference may be we leave to the reader to decide for himself. Our own idea is that it is considerable. The technical paper endeavors to give the information required by a particular profession; it aims to express the ideals of that profession; it takes its policy from the editorial, not the business, department; it is based upon the expectation of meeting the requirements of the particular profession. If it succeeds in these purposes, it is read by the members of that profession, and therefore its advertising pages become an effective medium for the display of the trade ministering to the requirements of that profession. On the advertising the prosperity of the enterprise depends, of course, but the editorial independence from the trade is essential to retaining the confidence of the readers. So long as the reading pages command the respect and confidence of those that have the say in the buying of the manufactures used in the profession, to the interests of which the paper is dedicated, so long will the advertising pages furnish an effective medium for merchandising those manufactures. Thus the trade meets the profession on neutral territory and business is stimulated without loss of integrity or independence on either side. That at least is the theory underlying the activities of the *Mining and Scientific Press*. It is well occasionally to make a confession of faith. We believe that by ministering to the current thought and knowledge of the mining and metallurgical profession, through reading matter carefully prepared, we shall cause a large proportion of the members of the profession to read this periodical; we also believe that if they read it, it will become an effective means of advertising the machinery and supplies used in mining and metallurgy. If we can do the first, the second will follow. That is technical journalism.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment

Speculation in Mines

The Editor:

Sir—It may be an open question whether mining is a more venturesome business than others. We are constantly reminded by statisticians that the majority of commercial and manufacturing enterprises fail. A bare 10% of the carefully calculated schemes of business men survive the uncertainties in production of raw materials, the vagaries of the markets, and the errors in judgment and foresight of those responsible for the operation. Nearly all endeavor in the world of business is a game of hazard. The miller who must grind grain and the spinner who must spin cotton to escape the financial perils that beset a halted enterprise is compelled to tempt fortune in the market, to take chances in making purchases when prices are reeling, and to risk consumption of his wares at remunerative figures. The merchant confronts identical difficulties, too obvious to necessitate illustration. Men plan and theorize, calculate and philosophize, while not a few consult mediums, and most of the time they are only guessing, and nine-tenths of the time are guessing wrong. Let us say, then, not merely that mining is speculative, but that business is speculative.

Surely no more than nine-tenths of the mines hopelessly and forever swallow the capital invested in them. It is necessary at this juncture to make haste to settle upon definitions, without which endless and aimless discussion must ensue. We must recognize that a mine is not a simple hole in the ground, nor a promoter's prospectus, nor yet a gudgeon's dream. A mine is a mineral deposit which has undergone sufficient development to warrant somebody who is supposed to know in seriously proposing it as an object on which worthily to spend money with a view to economic production. It is precisely like any other business. Someone thinks he sees an opportunity advantageously to make and sell mining-machinery, or pumps, or automobiles; many thousands see the vision but fail to materialize it; while out of the struggle for success emerges a Chalmers, a Deister, a Deane, and a Ford.

There must be a risk in developing a mine. It is commonly called a gamble. On the other hand, how safe are the chances for money placed in the hands of the enthusiast endowed with that poetic gift called imagination, who believes that the world has need of a new machine-shop and of him as its manager? Yet out of such visions come the successes that the world applauds. Out of the courage of the prospector, out of the faith of the men who follow up his discoveries with their money and their effort, come our Copper Queens, our Homestakes, our Nevada Cons., our Utah Coppers; and facing it fairly none can say that, save in exceptional cases, there exists a larger proportion of the speculative element in the development of these enterprises than in the creation of The Cotton Products Co., B. Altman & Co., The National City Bank, and the *Mining and Scientific Press.*

Keeping in mind that all enterprise is venturesome, it may be said that the evils of speculation in mining become more acute with a loosening of the money market and a tendency to rush incautiously into the business without taking advantage of engineering guidance and restraint. It is the mad spendthrift who disturbs the rational course of mining investment that is based upon well ordered technical formulae of probabilities.

COURTENAY DE KALB.

Tucson, Arizona, May 3.

Automatic Dressing of Amalgamating Plates

The Editor:

Sir—In 1909 I was assayer for the company which was at that time operating the Duplex mine, at Searchlight, Nevada. The mill, an antiquated 10-stamp affair, was in charge of Charles Hammil, one of the many clever mill-men to be found in the mining camps of the West.

The ore contained so much galena that the plates became coated with a heavy lead slime, which acted much like grease, after a run of only a few minutes. In spite of this fact the gold was surprisingly free, and it had become the custom to hang up one battery every half hour for the purpose of giving the plates a dressing in the ordinary way. Though this operation was quickly performed, the aggregate time lost was sufficient to appreciably cut down the daily capacity of the mill, the stamp-duty of which was already too low.

After giving the matter due thought, Mr. Hammil built over the plates, largely with his own hands, an endless brush something like a belt-conveyor. The motion of the brush was against the current and the plates were thereby kept bright and clean. It is further believed that a saving in float gold, which under ordinary conditions would have never come in contact with the plates, was effected. A set of brushes was installed on the plates from one battery and tailing-samples carefully taken and checked against corresponding samples from the adjoining plates. Good results were strikingly

evident from the first. The pulp below the brushes consistently ran from 25 to 40c. lower than the pulp from the other side. Unfortunately the plant was shut down shortly after this, and, to my knowledge, the experiment has never been tried again; there nor elsewhere.

The construction of the brush was simple. The bristles consisted of ordinary broom straw, mounted on wooden strips as long as the plate was wide. These strips were fastened, at the ends, to chains which passed over, and meshed upon, small sprocket-wheels set on shafts at the ends of a frame made of 1-inch gas-pipe. The frame was strongly fastened at the end next the mortar only, by hinges. At this end, of course, was the drive-pulley. The other end was free to be hoisted out of the way by means of a small block and tackle. A discarded belt was mustered into service and thrown over the line-shaft and the good work was begun. It is regretted that more definite data are not at hand but the above facts, such as they are, are offered with the hope that they may be of use to somebody.

E. S. Boalich.

Washington, D. C., April 24.

[Possibly the galena might have been kept in motion, and thus prevented from lodging on the plate, by giving it a higher velocity over the plate. The statement that the stamp-duty was low might indicate that too little water was used in the battery. Perhaps some of our readers will contribute a record of their experience with a similar ore.—Editor.]

Metallurgical Practice at Porcupine

The Editor:

Sir—I have read with much interest Mr. Poirier's notes on ball-mill performance at the Porcupine Vipond in your issue of April 17. Mr. Poirier is well qualified to speak with authority on the subject. Possibly one statement that he makes might be open to question, namely, that the tonnage of ore ground per horse-power is "double that of stamps." A performance with stamps that could readily be maintained at both the Dome and Hollinger, breaking from 2½-in. ring through ¼-in. mesh, was as follows:

Tons per 24 hours per 10 stamps	150
Horse-power, per 10 stamps	25 to 30
Tons per 24 hr. per hp	5 to 6

I believe the Vipond is treating about 100 tons per day, and that the intermediate crushing equipment consists of a pair of rolls and two 4-ft. Hardinge ball-mills. In order to break down double the tonnage per horse-power the duty of this equipment must be 10 to 12 tons per 24 hours per horse-power. In other words, 10 horse-power or less would be required to drive a set of rolls (the size of which I do not recollect) and two 4-ft. Hardinge ball-mills. The statement in my article to which apparently Mr. Poirier takes exception was "Power per ton of ore ground appears to be slightly higher than with stamps for the production of identical results," and I think that Mr. Poirier will find that this is borne out in Porcupine practice. It is a point of much interest at the present time, and as a sincere believer in the ball-mill, I shall be glad to find myself in the wrong if Mr. Poirier has data from actual practice to prove his point.

Noel Cunningham.

Denver, May 1.

Powder and Its Peculiarities

The Editor:

Sir—It is curious how differently powder acts under conditions apparently similar. I have been at the side of a man carrying a box of powder, when it fell and did not explode. Again, I have known it to fall from a man's shoulder and kill every one near-by. I once had a mule loaded with grain and 100 lb. of powder; the cargo became loose and frightened the mule, which ran away, scattering the powder for a hundred yards and even breaking sticks of it, but without any explosion. A number of years ago a pack-train of 22 mules loaded with powder out from Mazatlan, Mexico, disappeared. It is presumed a box fell off when loading. At any rate the whole pack-train, including the men, was killed. The remains proved insufficient for burial.

Once a partner of mine was thawing powder at an open-air fire while we were eating dinner. It caught fire and as we needed that powder badly, he grabbed a shovel and deliberately beat the fire out with it. I yelled, trying my best to stop him, and then, as he kept on, I ran; but there was no explosion. Later his carelessness caused the loss of his eyesight. While working in a 240-ft. tunnel we tried to fire six holes at the breast. One would not spit and, after lighting the others, we again tried to ignite it, but were finally obliged to run. The fuse still declined to spit, and the result was a misfire. My partner insisted on returning (probably 6 to 8 minutes later) to re-light it, while I built a fire to warm our coffee. I tried my best to persuade him to wait until after dinner, but he went and was just over the hole when it exploded. This fuse, examined afterward, showed no evidence of having been burnt. [The fuse declined to 'spit' and the result was that this one hole misfired.—Editor.]

A friend had an experience with defective fuse in the bottom of a shaft. The fuse would not light. He and the others waited the full noon-hour, when, upon entering the shaft, it exploded. I have known an ignorant man to throw powder down a 40-ft. shaft to a miner without it exploding. That miner, however, did explode; climbing the ladder, he chased the other man off the property. The latter never returned. I have seen boxes of powder thrown down a bank, 60 to 75 ft. high, sometimes breaking the boxes, and still without exploding. I have seen loose sticks thrown from one car to another loaded with rocks and bounce off the car without exploding. Again, powder has been known to explode from a very slight shock or fall.

I have seen two or three tons of powder burn up without explosion and again have seen it explode from the heat of a stove while being thawed. A few years

ago a ship-load was lost at the entrance to the Bay of Altata, at Sinaloa, Mexico, and after several months it was salvaged. It was so badly damaged that new powder had to be used with it in order to make it explode, but, the price of powder being high, it was all used.

The action under similar conditions of powder of the same make and strength is so different, that the utmost care should always be exercised when handling any explosive.

G. L. Sheldon.

Ely, Nevada, April 15.

The Editor:

Sir—The detonation of nitro-glycerine and its compounds, among which the best known are dynamite and gelatine-dynamite, can only be brought about by one of the two following causes: First, the elevation of the temperature of the nitro-glycerine to its explosive point, namely, in the neighborhod of 400°F., but this does not apply to the entire mass of the nitro-glycerine; it is only necessary for the smallest particle of nitro-glycerine. The heat liberated by the explosion of this smallest particle is quickly communicated to the adjacent particles and progressing with lightning rapidity, in geometric ratio, detonates the entire mass as if by a single impulse. Second, by the synchronous vibrations responding to a wave of detonation set in motion by an exploding mass of nitro-glycerine. This second cause may perhaps be referred to the first; for sound, heat, and light are all forms of energy and are convertible.

Strange stories are often told regarding the erratic behavior of dynamite, and a veil of mystery is generally thrown about the resulting accidents. These stories are often correct, but there is no mystery. It must be borne in mind that dynamites, even those of the same grade or degree of strength, are often not the same, that is, they differ in composition. Again dynamites of identical grade and composition often differ as to their physical properties. For instance, take two dynamites of the same composition, in the one that is the drier the 'dope' ingredients are further away from the saturation point; this will render it less sensitive than the other.

The question is often asked what makes a dynamite sensitive. Instead of answering this question, let us consider how a dynamite can be made less sensitive. When nitro-glycerine—a heavy liquid—was first discovered it was used as such and it was soon found that it was far too sensitive. Nobel incorporated kieselguhr, or infusorial earth, with nitro-glycerine and called this compound 'dynamite.' The modern dynamite contains an active absorbent, one that enters into the combustion of the explosive, and is ever so much more powerful than a kieselguhr-dynamite with the same percentage of nitro-glycerine. It is superior in every respect but one, and that is, it does not hold the nitro-glycerine as firmly as the infusorial earth did.

What is it then that renders a nitro-glycerine compound permanently less sensitive? Here again we have two causes: First, anything that dissolves in, remains with, and dilutes the ultimate particles of nitro-glycerine. When once in solution and with the proper solvent there cannot be any stratification. This insures less friction between the ultimate particles of nitro-glycerine and then, again, these particles will be hampered in their effort to vibrate synchronously in response to a detonating wave. Second, anything that will dissolve in, become a part of, and hold rigid the ultimate particles of nitro-glycerine, preventing friction and hampering vibration, will render the nitro-glycerine less sensitive. This is accomplished by collodion cotton dissolving in nitro-glycerine and converting the same into blasting gelatine or with 'dope' into gelatine-dynamite.

Dynamites are not the same, neither as to chemical composition nor as to physical condition and the latter is largely influenced by atmospheric conditions—temperature and barometric pressure. All explosive phenomena must be referred finally to an elevation of a particle of nitro-glycerine to the explosive point. This may be occasioned by a sharp blow or fracture of a frozen crystal of nitro-glycerine or the gradual storage of heat generated by some slow process of oxidation akin to spontaneous combustion. The 'dope' materials are in general bad conductors of heat.

Harry East Miller.

Oakland, April 28.

[At our request, Mr. Miller has given increased value to Mr. Sheldon's letter by furnishing the above information. Mr. Miller is a recognized expert in such matters, and we are much obliged to him.—Editor.]

Heulandite in Oregon

The Editor:

Sir—Among some mineral samples recently sent to the University of Oregon for identification I found a specimen of heulandite. As there is no record of this mineral having been found in Oregon before, it is of interest to record this occurrence. This mineral was found on Rowe river ½ mile below Dorena, Lane county, Oregon. It occurred as the lining in a cavity in basalt.

Graham J. Mitchell.

Eugene, Oregon, May 4.

[Heulandite is a hydrous silicate of lime and aluminum, belonging to the group of minerals known as the zeolites; so named because they appear to boil before the blow-pipe. It usually occurs in basaltic rocks and has been recorded at many places in the eastern United States. It is found occasionally in metalliferous veins.—Editor.]

No. 1 converter at the Washoe plant, Anaconda, has produced 60,000,000 lb. of copper from matte; also 15,000,000 lb. from white metal transferred to it from other converters. The total was 75,000,000 lb., in slightly over 12 months. It is a 20-ft. diameter Great Falls basic-lined type.

Industrial Journalism

By HORACE M. SWETLAND

*Industrial publications must at all times be considered as serving three separate and distinct functions of an industry, and usually these three functions are served by separate and distinct publications, inaugurated by distinct individuality, and usually operated by separate and distinct ownership. The paper serving the first of these three functions is one devoted to the interest of the manufacturer, and having a circulation among the superintendents, experts, and owners in one special line of manufacturing, and an advertising constituency among those who supply raw material or machinery to this line of production. An illustration of an industrial publication, serving this function, is the *Textile World Record*, published in Boston, reaching the industry of textile manufacture, and having subscribers among the textile mill-owners, superintendents, and experts, and an advertising patronage from persons furnishing raw materials and machinery used in the manufacture of textiles.

The second function of industrial journalism has to do with the merchandising of the manufactured product, and has its circulation among the jobbers, dealers, or merchants selling this special product, and an advertising constituency consisting of the manufacturers of this product, illustrated by the *Dry Goods Economist*, with a circulation covering the dry-goods merchants and jobbers, and an advertising patronage from the manufacturers of textiles.

The third function of industrial journalism is served by a publication devoted to the interest of the ultimate consumers of the product of a special industry, educating them to a proper selection of the manufactured product, and the correct uses and service of this product, illustrated by *Vogue*, an industrial publication devoted to the interest of the user or consumer of the product of the textile manufacturer, and sold to them by the textile dealer.

These three phases of industrial journalism must be kept well in mind, namely, the paper devoted to the interests of the manufacturer, the merchandising paper serving the dealer, and the paper devoted exclusively to the interests of the consumer. At present, industrial publications sometimes endeavor to serve two or more of these functions, but eventually each industry of sufficient importance and of a sufficiently distinct character to require journalistic representation, will be served by a publication devoted especially to one and only one of these elements.

Industrial journals differ from all other forms of journalistic production in that they are not basically constructed to please and entertain the reader, and thus create and maintain a great sale for a publication. Unless the publisher knows the journalistic requirements of his constituency, and raises his reader to the level of his publication, he should retire to the ranks of yellow journalism. No doubt, the evolutionary process will serve the industrial press for some time before the rank and file arrive at a true conception of their mission. But all the great papers of the industrial press today are conducted on this basic principle of making the paper which the industry needs, while the number who are trying to please or entertain a class of industrial readers are growing continually less, and are joining the ranks of those who try to please everybody. Not that a constituent of the industrial press is less susceptible to entertainment or pleasure than the average reader, but he does not buy his industrial paper to be entertained. He has subscribed to the publication with the sole idea that it will be of service to him in his business, and he reads it in his thoughtful moments. If he were competent to dictate the kind of a paper he should have, the need for the publication would be very much lessened. He, therefore, should leave the problem of making the paper to the publisher, just as he leaves the painting of his pictures to an artist, and we wish to disclaim, once and for all, any successful policy on the part of the industrial press of trying to find out what the industry wants, and then pandering to the palate of ignorance or prejudice. The service of the industrial press, for this one basic principle, is of great value to an industry, just as the text-book is of value to the student, and as the picture designed and executed by the artist is superior to the conception of the ordinary purchaser.

The services of a competent journal, devoted exclusively to one of the three phases of an industry, may be classed as general and specific. The general or indirect service probably exceeds the specific or plainly apparent benefits, just as the indirect results from advertising exceed the direct returns. Just as the subtle influence of a great sermon, a great message, or a great editorial, rings true and awakens sentiment and feeling, which, in turn, inaugurates great reforms, so the promulgation, discussion, and reiteration of the great problems of an industry make possible a more intelligent solution than can be secured by individual effort.

Not that the editor of an industrial publication has supreme knowledge of all matters pertaining thereto, or assumes to be more wise than the combined intelligence of his constituency, but if he is even moderately successful in fulfilling the great obligation of his calling, he has command of, and access to, more sources of information than the layman. An editor is not expected to know everything. He is not a walking encyclopedia, but his work is intelligently indexed to the extent of quickly availing himself of the latest information from field or laboratory, and standing thus apart from active participation, with a clear field for perspective observation, unbiased by contingent individual conditions, he is able to reflect a consensus of intelligent opinion, of the greatest value and of lasting benefit to his readers. And in doing this he will find his chief reward.

*Part of address delivered before the New York University Forum on Industrial Journalism, March 24, 1915.

Stoping Methods at the Nevada Wonder Mine

By THOMAS M. SMITHER

The Nevada Wonder vein is of the fissure type, inclined at an angle of 75°; the foot-wall is rhyolite; and the hanging wall rhyolite, or occasionally dacite. The orebody itself, in most cases, is much fractured and crushed; the gangue consists principally of quartz, feldspar, and kaolin. The average width is five or six feet. No water is encountered. The walls in the lower levels are insecure and cave away in large masses, thus rendering useless both the stull system of support and the shrinkage system of stoping; although the shrinkage system was used to great advantage from the 400-ft. level to the surface, where the walls were fairly firm and stood well.

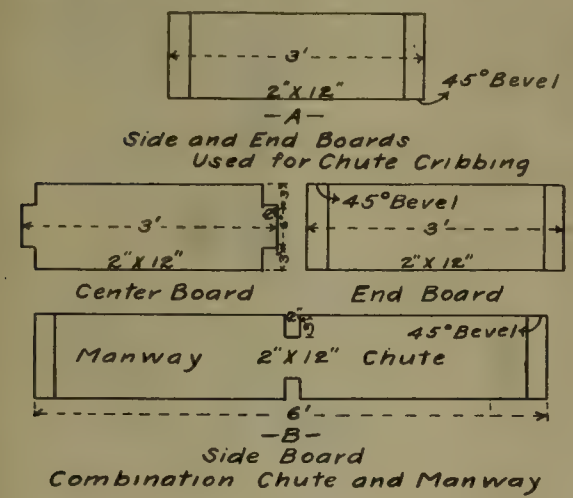

FIG. 1.

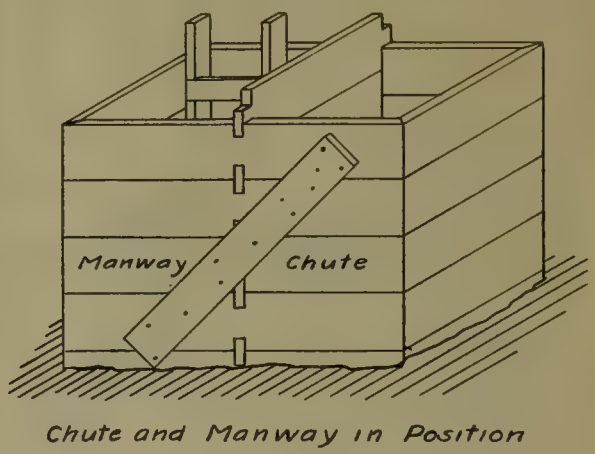

FIG. 2.

The method at present employed is a waste-filling system. The salient features are:

1. The mining of waste material for filling, from the walls of the stope, by inclined rises.

2. The cribbing system of chutes and manways, using a minimum amount of timber.

As the waste broken during development cannot always be economically transported to the stopes requiring filling, the method of breaking waste by means of inclined rises was adopted. The small amount of timber required by this method is an important consideration, as all supplies are hauled from Fallon, Nevada, the nearest railroad point, which is 60 miles distant, thus making the cost of timber somewhat excessive.

The cribbing used for ore passages are cut from 2 by 12-inch Oregon pine lagging, to the dimensions shown in A, Fig. 1, and are built up by placing upon the 2-in. edge (Fig. 2). When both a chute and manway are desired, the cribbing is cut as in B, Fig. 1. A 24-in. swinging circular saw is used to cut the cribbing; it is of the American, Style D, type, and is self-contained and electrically driven. This saw has been arranged for the purpose at the mine, and is also used to cut stulls and other timber. The saw and the details of the arrangement for cutting the cribbing are shown in Fig. 3 and Fig. 4.

The first thing done is to start the stope by making one cut above the back of the drift. A row of stulls and posts is then placed in position. The stulls are covered with a layer of 3 by 12-in. planking, and chutes and foundations for cribbing are built in (Fig. 5). The first few sets of cribbing are constructed of 3 by 12-in. lagging instead of the usual 2 by 12, to secure a firm foundation. A rise for waste is next started and sufficient waste is broken to cover the flooring to a depth of 2 or 3 ft., for protection of the timbers. The waste is then leveled off and covered with a plat of 2 by 12-in. plank to receive the broken ore. The waste-rises are started as near the back of the stope as possible, by this means securing a greater length of service.

The stoping now proceeds in a series of steps. The ore in one end is drilled and shot down; sufficient is then drawn out to leave just enough head-room for a miner and a Waugh drill to operate efficiently. The back is next drilled with 5-ft. holes, and the holes left unloaded until required. This drilling upon the broken ore gives the miner a safe position close to the back and at the same time prevents falling masses of ore from mixing with the filling. As soon as the drilling is completed, as much ore as possible is drawn out through the chutes; the remainder is shoveled into them and where necessary wheel-barrows are used. The plat is next taken up and waste-filling begun.

The chutes and manways are first built up several sets and temporarily held in position by a brace of

plank, spiked across them, as shown in Fig. 2. The edges of the cribbing are toe-nailed together. The inclined rises are next driven upward until enough waste is broken down. This waste runs into the stope by gravity and is leveled off by the shovelers, and the plat of 2 by 12-in. lagging laid upon it. The filling is carried to within three or four feet of the back, and is level with the topmost edge of the chute-cribbing.

While the waste-filling is in progress, the miners drilling the ore are continually advancing toward the opposite end. A uniform procedure is maintained, one end above a manway, the opening is closed with a cover of 2 by 12-in. plank, nailed together. This cover is removed as soon as possible after blasting, for ventilation and entrance purposes.

When about to break through to the level above, the system of timbering shown in Fig. 6 is used to support the filled stope overhead. By this means all of the ore is removed and the ground solidly filled.

The advantages of this method, where weak and swelling walls are present, are:

1. The secure and safe support of the stopes.

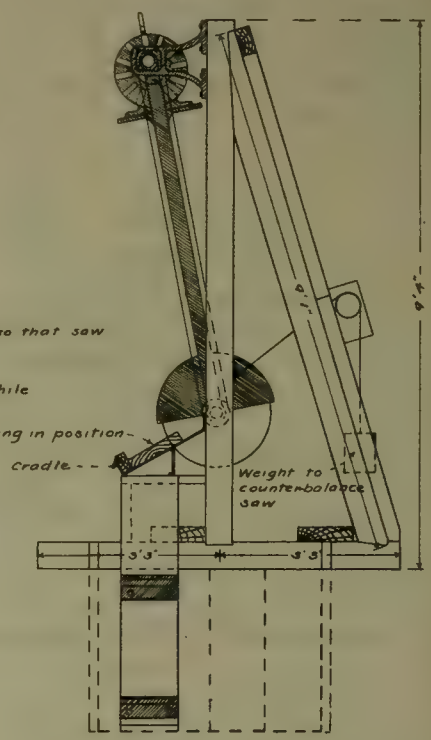

FIG. 4.

being filled with waste, while ore is broken at the other; upon arriving at the far end the miners return to the original starting point and proceed as before. A 5-ft. strip, the full length of the stope, is removed each time, 40% 1⅛-in. E.L.F. Hercules gelatin being used for blasting. When speed is necessary more miners are used and stoping proceeds from both ends to the middle.

The waste-rises are driven alternately into the foot and hanging walls, by Waugh machines, at an angle of from 40 to 50°. The rises are placed so that one is between every two chutes, and they are used for two or three fillings. The heights of the rises vary, depending upon the amount of waste required, but they seldom exceed 30 or 40 feet.

A combination chute and manway is carried up at each end of the stope, with as many as are necessary at intermediate distances. One manway is always open, and more when possible. When ore is to be shot down

2. The minimum use of timber, where timber is an expensive item.
3. The waste-rises serve as cross-cuts, for prospecting.
4. The elasticity of the method. The required tonnage can be broken down at any time, since the back is kept drilled ahead of requirements.
5. The removal of the ore, as no pillars are left.

The disadvantages are:

1. Low-grade material, which might be worked economically at a future date, must be left. At the Nevada Wonder mine, however, little is lost in this manner.
2. The shoveling required.

These disadvantages are more or less present in all waste-filling systems and under the conditions described are of minor importance.

In conclusion, I wish to state my appreciation for information given by Mr. J. A. Burgess, superintendent, and Mr. W. Frazee, foreman.

Assay of Cyanide Solutions

By C. E. ROODHOUSE

In the laboratory of the modern cyanide-plant it is essential to make use of processes of determination that not only are accurate, but that combine well with one another in the daily routine. With these points in mind I have evolved the following modification of the Chiddey process of determining gold and silver in cyanide solutions. It is not widely different from other excellent modifications that have been proposed from time to time, but it possesses the advantages of producing complete precipitation and of requiring little manipulation and almost no watching during operation.

To avoid scorification of lead sponges the solutions must be fairly free from slime and colloidal matter. Cloudy solutions that refuse to settle or filter can usually be cleared by adding a little lime-water, boiling a moment and then filtering. Slime or colloidal matter in the solution will be collected in the sponge, and will cause the molten lead to scatter during cupellation.

For solutions of ordinary grade a 5 assay-ton charge is desirable; 10 A.T. is usually sufficient on precipitation-tailings and low-grade solutions, but in case of very low-grade solutions it is advisable to run two or more 10 A.T. charges, and to combine the buttons for cupellation; 1 to 2 A.T. is sufficient for rich solutions.

For the small charges use 400 c.c. beakers of squat form, and 600 c.c. beakers for the larger ones. Beakers of these sizes are preferable to smaller ones, since they allow the formation of flat sponges of large diameter that hang together well, and that permit more rapid solution of the zinc than do the ball-like sponges formed in small beakers. The solution of lead acetate may vary in strength, but the 20% solution of C. P. salt is a convenient one to use. It should be acidified with acetic acid just sufficient to render it stable.

After many tests with sheet aluminum, sheet-zinc, zinc-dust, and zinc-shavings I have come to rely on the latter as being the most dependable for all conditions and grades of solutions.

Fine, freshly cut zinc-shavings will produce perfect precipitation and coherent sponges in solutions where the other precipitants mentioned fail. It is necessary to use shavings that are not oxidized appreciably.

After measuring the charges of cyanide solution, add 20 to 25 c.c. lead-acetate solution and 1 to 1½ grams of zinc-shavings. By using the shavings in long strips as they come from the lathe the operator can cut off the correct amount without weighing, after a little practice.

Place the charges on the hot plate, fill beakers up to three-quarters full with hot water, and bring to boil as rapidly as possible.

Just before the boiling-point is reached, add 1 to 2 c.c. acetic acid and allow to boil a minute. The addition of acetic acid at this stage produces firm sponges that do not break up later under the action of HCl on the zinc; but if added before this point is reached it does not always give as good results.

After boiling a minute pour off solution closely, add 150 c.c. hot 10% HCl, set back on hot plate, and cover with watch-glasses. Ten to twelve minutes of rapid boiling will dissolve the zinc; then fill the beakers with cold water, decant, wash once more with cold water, squeeze the sponges into cubes, and dry. It is always advisable to wrap the cubes in lead-foil to prevent the lead from separating into several buttons while cupelling.

The accuracy and reliability of this method depends upon:

(1) The dilution of the solutions with water.

(2) The use of zinc-shavings for the precipitant.

(3) The addition of acetic acid at the proper time to form solid sponges that will permit rapid solution of the zinc without disintegration.

(4) The pouring-off of the original solution before adding HCl.

If the last two points be carefully followed, disintegration of sponges will be rare indeed. Prolonged boiling in HCl will cause it; but this need never happen.

Based on average speed of manipulation in conjunction with other work, 12 assays will require about 45 minutes, as follows:

	Minutes.
Preparing charges and placing on hot-plate	6
Time required to bring to boiling and to boil 2 min.	15
Time required for decanting solutions, adding HCl and dissolving zinc	18
Washing and squeezing into cubes	6

To facilitate manipulation it is a good plan to add lead-acetate solution from a dispensing burette with a large bore through the stop-cock; also to prepare HCl solution in quantity and to heat enough for the day's run at the same time that the charges are heating. The acid solution can be added sufficiently accurately without measuring. The acetic acid may also be added from a smaller burette without removing beakers from the hot-plate.

While there may be some solutions that will fail to give satisfactory results with this method, I have not thus far found them; I do find that it gives more consistent results on a great variety of solutions than any other that I have used.

MINERAL PRODUCTION of Tasmania in 1914 was worth £1,007,038, against £1,415,700 in 1913. The principal materials were as follows:

Product.	1914.	1913.
Bismuth	£ 1,666	£ 1,627
Coal	27,853	25,367
Copper, blister	477,361	364,732
Copper ore	18,680	10,932
Gold	111,475	141,876
Osmiridium	10,076	12,016
Shale oil	75	130
Silver-lead ore	96,225	319,997
Wolfram	4,327	7,040

On account of the Tasmania mine at Beaconsfield being closed, the gold yield decreased, while the silver-lead output was seriously affected by the war.

Technical Reminiscences—I

By ALBERT R. LEDOUX

At the request of the editor of the *Mining and Scientific Press*, I set down without any attempt at 'fine writing' some reminiscences that he has been kind enough to intimate might be of general interest.

In view of the recent death of Lord Rothschild, it seems timely to commence with an account of some of my experiences with this great firm which have extended over twenty years. The beginning of this most pleasant and interesting relationship came about 'by accident' as we call it, as indeed, have many of the most interesting experiences of my life.

I happened to be in London and met in the street Mr. Abraham Lazarus, then head of the well known firm of metal-brokers, Lewis Lazarus & Sons. He seemed unusually glad, and rather surprised, to see me; he looked at his watch and asked me if I had any engagement at the moment, for, he explained, Mr. Alfred de Rothschild was in the midst of an important negotiation concerning a matter that involved a certain mining and metallurgical enterprise in another country, and had asked him to find some man in London who knew something about the properties involved in the transaction and to bring him in that day, at one o'clock. Mr. Lazarus had been searching the city in vain; it was then a quarter to one. I told him I would be very glad to serve him and the Messrs. Rothschild, whom I had never met, and that I had some knowledge of the properties in question. I went immediately with him to New Court and was introduced to 'Mr. Alfred,' as he was known, who impressed me as a man accustomed to trust everybody, and above petty suspicions, for without knowing anything of my antecedents or business, he immediately frankly explained the situation, asking me if I knew Mr. Blank, who was either interested in the mine or was acting as an intermediary in the contemplated transaction. I said that I knew Mr. Blank well, but our relations had never been such as would prevent my giving Mr. de Rothschild any information I had; that my knowledge of the properties in question had come without placing me under any obligations to anyone. Mr. de Rothschild pulled out of his desk a memorandum of figures and a statement concerning the character and grade of ore, cost, and method of treatment. These he said he wished to verify. I was able to express an opinion as to the accuracy of the statements and figures in most cases, and to give him suggestions as to pertinent questions that he should ask the other party at their meeting, which was to take place that afternoon.

Mr. de Rothschild asked me to breakfast with him the next morning at his residence on Park Lane. I remember the impression his beautiful and artistic home made upon me at that time—its magnificent paintings, and particularly the fact that I awaited my host in the library, where a table bore many priceless souvenirs, some set with jewels, many made of gold, and some bearing autographs of kings and other great men who had presented them. I could not help wondering whether it was the custom to leave all visitors—even strangers—alone in such a room. I remember also that the breakfast, while elaborate for my benefit, was not shared by my host, who confined himself to tea, toast, and ripe figs.

He told me that the other party to the negotiation had seemed greatly surprised at Mr. de R.'s sudden acquirement of accurate knowledge of conditions, and showed me the answers that had been made to the inquiries suggested by me. These I discussed, pointing out where they agreed or disagreed with my impressions, and suggesting further inquiries. I offered to hold myself at the disposal of Mr. de R., and he, in turn, asked me to communicate to him any new suggestions that might occur to me.

That day, I had occasion to go to Swansea to inspect a new metallurgical process. On my way down, an idea came to me that I thought might be valuable and I decided to telegraph to Mr. de Rothschild; but I did not think it wise to be explicit in a telegram addressed to so prominent a man, not knowing who in Swansea or in London might see the message. I had been introduced to Mr. de R.'s private secretary, Mr. Roche, and addressed my telegram to him, asking that he tell 'Mr. A.' so and so. I found afterward that this precaution had greatly pleased my client.

I never knew or inquired what was the result of the negotiation, but called at New Court before going to the Continent to ask if I could be of any further service. I was told to call again before I sailed for America; this I did some weeks later. There never for a moment entered my mind any thought of being compensated financially for my advice and suggestions. I had been greatly pleased and interested in being admitted for a moment to the inner circle of this group of financiers of world-wide reputation and never expected to be called upon for any additional service. The day before I sailed, I called to say good-bye, and was asked if I would be willing to hold myself ready to advise Mr. de R. in any matters in America about which I might have knowledge and concerning which he might desire to consult me. Nothing was said about compensation for my prospective services; but when I arose to leave, as if just then recollecting something, Mr. de R. said: "Oh, by the way, Mr. Ledoux, after you left I learned that Rio Tinto shares were likely to go up, purchased some for myself and took the liberty of buying some for you, in your name. The shares have gone up, so there must

be a profit on your book account; perhaps you would like to sell out and take it." I said I would gladly do so. He then rang for a clerk and asked him "how Mr. Ledoux's account" stood. This clerk stated that on such a day Mr. Ledoux had bought through them so many shares of Rio Tinto at such a price; that the market that morning was so and so. Mr. de R. said, "Mr. Ledoux wishes to take his profit. Telephone to sell his shares and bring him the net proceeds." In a few minutes the clerk returned. With renewed apologies for having presumed to represent me in a financial transaction without my permission, Mr. de R. handed me Bank of England notes for a sum that I would have considered greatly in excess of any compensation due me for the time I had expended.

I mention this transaction as typical of Mr. de R.'s method of doing business, and because it is so different from what one might expect from many people, however important. From that day to this, it has been a pleasure for me to render service to the Messrs. de Rothschild, and never has there been any agreement as to compensation for services rendered. They are usually requested in a cable, but the remuneration is never forgotten at the proper time.

Of course I cannot make public particulars of these professional services that from time to time have been rendered; but I will mention one because of its unusual character and the interesting events that led up to it.

I must digress here to say something as to the beginning of my acquaintance with the late Marcus Daly. I had known the late James B. Haggin for some years, and have many interesting memories in connection with our business and personal relations. At the time of which I am about to write my firm represented the Anaconda company in handling shipments of rich ore, sent to Great Britain for smelting and refining, and in the export of Anaconda copper matte just then beginning; but I had never met Mr. Daly himself. One summer my mother was at a seaside resort in New Jersey, and I went down to spend the week-end with her. She pointed out two ladies who she said were named Daly and were from somewhere in the West, a mother and daughter. She said that they did not seem to know anybody, so she had introduced herself to them, had taken them for several drives, and found that her attentions were gratefully accepted. That afternoon while we were all upon the piazza, a man drove up and greeted the Daly ladies affectionately. My mother and I noticed them looking toward us as they talked. Later, Marcus Daly came up to me and asked if I was the Ledoux that had a laboratory in New York and had been handling Anaconda products. He said his wife had told him of my mother's courtesy, which she greatly appreciated, as did he; that it was probably not in his power to do anything in return for my mother, but that if ever he could serve me in any way, he would be glad to pay through me a debt which he felt he owed to my mother.

Some six months later, my wife and I were occupying the private car of a transcontinental railway for which I was doing some field-work. We were sidetracked in the yards at Butte. I received a cipher message from my office in New York, saying that a cable had just been received from the Rothschilds, asking me to go to Montana and try to ascertain whether Hamilton Smith and Louis Janin, who were examining the Anaconda mine for the Rothschilds, were likely to make a favorable report. This seemed to me a pretty large contract! I had met Smith and Janin at the Silver Bow Club and everybody knew that the Rothschilds had an option on a certain interest in the Anaconda, for it had been so stated in the papers. Of course I could not honorably seek to find out anything from Hamilton Smith, even if it were possible, but I ascertained that he expected to take some three weeks more for his examination. I was at an utter loss what to do, when I remembered Daly. I decided to take him into my confidence, and showed him the cable. He expressed himself delighted at the opportunity to serve me and said that the task imposed was not impossible of fulfilment, if I were willing to work hard. He showed me a copy of the option, which contained the vendor's statement as to ore reserves, costs at Butte and Anaconda, statements of the tonnage being mined and the grade of the ore. Together with Daly I went over the records at Butte and at Anaconda, spent several days or nights underground, and satisfied myself that the conditions of the option would be met unless it were that the grade of ore proved too low. I did not feel justified in arriving at a conclusion based on the assay-sheets alone, and I hit upon a plan for checking them. In those days, the ore from the various shafts of the Anaconda properties was assembled in car-loads in the railroad-yards, where trains were made up for hauling to Anaconda. When these trains were made up, the flat cars bumped together and there was spilled along the tracks a considerable quantity of ore, which fell off the sides, so that there was a double ridge a quarter of a mile long. Once a day, this ore was shoveled into empty cars. At midnight I took a coal-hod and shovel from my car and walked down one side and up the other of the ore-train, taking a shovelful of this ore at regular intervals. The samples were assayed next day at Butte. The results checked closely with those of the laboratory of the mine at Butte and with the report of the sampling at Anaconda; I felt sure therefore that the question of grade must be answered affirmatively by the Rothschilds' engineers, so, within a week from the time I had received the cable, I replied that in my opinion, the report of Smith and Janin must be favorable. This turned out to be the case.

Since that time, I have been frequently at New Court, have watched the beginning of many important affairs, and have had personal knowledge of the great power of this banking-house—not only in finance, but in influencing social and economic conditions of many countries. I shall mention one illustration.

I happened to meet the late Theodore Armstrong,

President of the Pennsylvania Salt Manufacturing Company. He told me that he was in London endeavoring to secure a contract for 250,000 tons of Rio Tinto 'pyrites' partly for his own works and partly for the Standard Oil subsidiaries, which he represented. He said that he feared his contract would fall through because the Rio Tinto company insisted that he take the 'pyrites' free on board at Huelva; that the Spanish government had permitted the entrance to the port to become filled up to such an extent that only boats of comparatively small draft could cross the bar; that he could pay the price asked for the pyrite if he could get large ships into the harbor, upon which the freight-rate was somewhat less than upon smaller vessels. I took Mr. Armstrong to New Court and introduced him to Mr. Alfred de Rothschild. I knew that he was interested in the Rio Tinto and thought possibly the introduction might lead to a somewhat lower price being quoted, under the circumstances. Mr. de Rothschild, upon learning that the contract was not to begin for a few months, said that Mr. Armstrong could sign it with confidence and that the difficulty would be removed. I never heard what steps were taken, but a few weeks afterward I saw in a Paris newspaper the statement that the government of Spain had ordered immediate steps to be taken to dredge the bar at Huelva to permit the free entry of large vessels. Evidently Mr. de Rothschild had spoken the timely word.

Apex Litigation. Jim Butler v. West End

By H. V. WINCHELL

The elaborate opinion accompanying the decision handed down on April 30 by Judge Mark Averill of Tonopah in the above entitled cause is in many respects of unusual interest. Noteworthy because of the array of legal and technical talent engaged, it is also important in establishing a precedent as to the law in exceptional geological conditions and in deciding questions that have not heretofore arisen in mining litigation.

Although apparently simple in its intent and wording, the apex law of the United States, designed by its framers to apply to an ideal condition, has been so stretched in the endeavor to cover all classes of metallic mineral deposits that it is now in a state of great complexity and confusion; and not even the most learned and experienced legal practitioner can say in advance what will be the ruling of the courts under conditions slightly different from those which have been already adjudicated. The present law was enacted in 1872, and it is not surprising that the statement is often made by those who are poorly informed that the interpretation of the law is now complete, and that no more new questions remain to be fought over and settled. That this statement is not true, and that there is in sight no limit to the number of new questions which may arise for interpretation is known to many, and is illustrated in the case now to be discussed.

Generally speaking, the owner of a 'lode claim' under the Federal mineral-land law is entitled to follow and mine his veins downward upon their dip into the earth from their tops or apices within the said claim even though he passes beneath the surface of land owned by others. This right is, however, subject to certain restrictions and limitations:

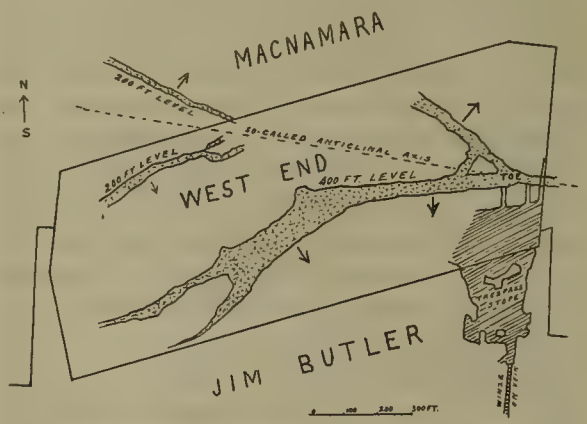
1. Its direction depends upon the relation of the apex of the discovery-vein to the boundaries of the claim.

2. The 'extra-lateral right' can only be enjoyed between the planes of the end-lines of the claim extended in their own direction.

3. If the apex of the discovery-vein crosses both side-lines of the claim as located, these side-lines become end-lines for the purpose of determining the direction and extent of extra-lateral rights, but

4. In either case, in order that there may be any extra-lateral rights, the end-lines (*de facto* or constructionary) must be parallel or at least not diverge in the direction of the dip.

5. Where the apex of the discovery-vein crosses one located end-line and one located side-line of the claim, extra-lateral rights are allowed, as the law has been judicially interpreted, a new theoretical vertical boundary being erected for such rights, parallel with the located end-lines and passed through the vein at the point where it departs from the claim through the side-line.



PLAN OF CLAIM AND OREBODIES.

6. Because they are thus important in fixing the direction of extra-lateral rights the end-lines must be continuous and unbroken.

There are many other principles which may be regarded as now definitely established by court decisions, but there are still many points of uncertainty, and

among them are at least two which have been for the first time passed upon in the Jim Butler-West End case. In the first place, Judge Averill has decided that although a claim was located on a discovery-vein which dips north it may also have extra-lateral rights upon other veins apexing within its boundaries which dip south. In the second place, he has held that, although a claim has a broken end-line, yet, where its discovery-vein crosses a located end-line, and then passes out through one of its side-lines before it reaches the other end-line, the defect in the location is not material, and the claim has extra-lateral rights for the extent which it has apex in the same manner as a claim with parallel end-lines. There is also in the present case a decision that a top or apex exists in the West End claim under the rather unusual conditions hereafter described.

The plaintiff, Jim Butler Tonopah Mining Co., was represented by its chief counsel, Judge Curtis H. Lindley, the author of the standard treatise 'Lindley on Mines,' and his associate, Mr. William E. Colby, and by Mr. Hugh Brown, of Tonopah. As expert witnesses they presented Prof. Andrew C. Lawson, of Berkeley, Prof. John W. Finch, of Denver, Mr. Fred J. Siebert and Mr. Fred Searls, Jr., of Nevada.

Chief counsel for the West End Consolidated Mining Co. was Hon. W. H. Dickson, of Salt Lake City, who was assisted by his partner, Mr. Ellis, and by Messrs. Peck, Bunker & Cole, and Horatio Alling, Jr., of Oakland, Judge S. S. Downer, of Reno, and Mr. Harry Atkinson, of Tonopah. As expert witnesses appeared Messrs. W. H. Wiley, of Los Angeles, E. C. Juessen, of San Francisco, John W. Chandler, of Tonopah, and H. V. Winchell, of Minneapolis.

In the course of its mining operations, the West End company had followed downward upon a vein from beneath its own surface under ground owned by the Jim Butler company. Ore of considerable tonnage and large value had been extracted, and although the West End company, in the desire to avoid expensive litigation, offered to divide the ore and the proceeds already accrued, the offer was rejected and suit was instituted to recover triple damages for wilful trespass. The amount thus sued for was in excess of $3,000,000, and the suit took on serious aspects.

The geology of Tonopah is not simple. There is a series of volcanic rocks which intrude and overlap each other like a pile of batter-cakes unevenly arranged, and of varying thickness. The productive veins are found to a large extent within what is called the Mizpah trachyte formation. This trachyte is believed to be older than the other volcanics, some of which have been intruded into it, and others of which have flowed out upon it, and still others of which are in the nature of overlying tuffs or volcanic breccias. One important rock is the West End rhyolite. It has been intruded into the trachyte in the form of an irregular sheet. Another widely spread eruptive is the Midway andesite. The latter rests upon the trachyte and conceals it from view throughout the area in controversy in this case. The veins do not enter the Midway andesite. They are supposed to have been formed prior to its extrusion; and it is even suggested that there was a time when the veins outcropped on the surface of the ground, and that the andesite flow covered these outcrops. There was a still later volcanic breccia, called the Brougher Mountain or Fraction dacite-breccia, whose relation to the veins and to the other rocks was a matter of some discussion in the case.

The veins of Tonopah do not commonly outcrop on the surface. They generally terminate upward against the Midway andesite, and are thus buried to varying depths, from nothing to 1200 ft., depending on the thickness of this 'cap-rock.' Nor do they all lie in one and the same country-rock. They are found cutting the trachyte, extending downward through it to the West End rhyolite, following along the contact for a distance, then cutting through the rhyolite to another intrusive rock which underlies the rhyolite, and again taking up a position on this 'lower contact.' They thus have the characteristics of fissure-veins which for a considerable distance lie upon or in the planes of contact between eruptive rocks.

As shown by the plan, there appear to be two veins on each level, except in the vicinity of the 'toe.' One of these veins strikes northwesterly and dips northerly. This is the vein which was encountered in the discovery-shaft of the West End claim. The other vein strikes somewhat north of east, and dips southerly, and it was on this south-dipping vein that the alleged "trespass stopes" were made. It will appear from the plan that, on each level, these veins approach each other on strike, coming together along an axis or line of junction which inclines or pitches to the east.

It was shown by the testimony that these two veins had been usually considered as one vein, called the West End-MacNamara vein, and that there were stopes in the mine upon the north-dipping vein which had been carried up to a point where the vein became first flat and then assumed a dip to the south. The vein was therefore termed an 'anticlinal' vein, and the question was raised whether it was all one vein, and whether as a matter of fact being completely buried by andesite, and having no outcrop, it had any "top or apex" within the meaning of the statute.

No plane of cross-section will show precisely the same conditions as to overlying and underlying rocks for any considerable vertical distance. The section shown herewith is, however, substantially one which represents the structure near the eastern end of the West End claim. In this part of the ground, although there is a great amount of quartz beneath the crest of the so-called anticline, the arch is either broken, and one side thrust over the other, or else there is evidence of two different veins, one slightly subsequent to the other, and overlying its present top or terminal edge. That portion of the vein shown on the section between the point marked *A* and the Midway andesite cap-rock was the chief battle-ground of the contest. The Jim Butler witnesses claimed that the quartz in certain rises upon that part of the

vein was not vein-matter in place, and at most nothing more than a part of the "halo" or "stringer zone" of the vein. The West End witnesses maintained that these rises show the full thickness of the north-dipping vein, containing ore with characteristic structure, and that this vein not only overlay the south-dipping vein, but had moved on it so as to be cut by it, as shown in the section.

The West End company claimed to be the legal owner of the stopes in controversy by virtue of its patent from the Government, alleging (1) that it had an apex more than sufficient to cover the area from which ore had been extracted as alleged in the complaint; (2) that although its discovery-vein dipped to the north, while the alleged trespass was on a south-dipping vein, yet that its rights extended also in that direction; (3) that its lode-claim was correctly laid out and patented and that there was no impediment to extra-lateral rights in the shape of its west end-line.

To these claims the Jim Butler company objected on the following grounds:

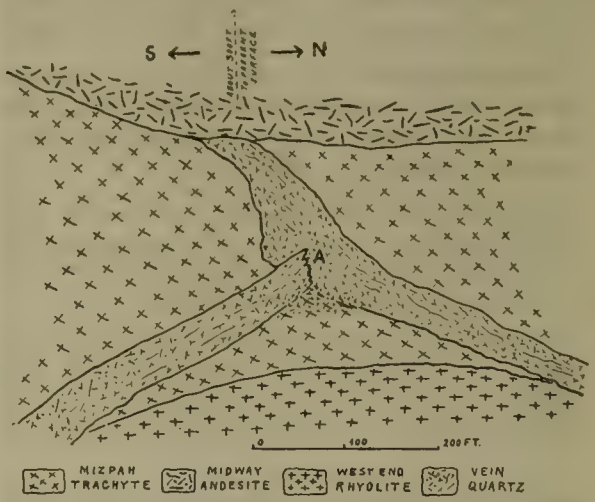
(1) The vein has no "top or apex" such as is contemplated by the statute. That it is a 'blanket' or contact vein, which not only does not reach the surface but which has no terminal edge unless it be one which extends in a general northerly and southerly direction near the west end of the claim, and which crosses both side-lines and thereby constitutes them really end-lines. On this point Judge Averill finds that "this contention is without merit. * * * Its termination, as that now exists in the westerly portion of the West End claim, is the result of the eruption of the volcanic neck known as Mt. Brougher." He finds abundant evidence of apex, showing a diagram of his own making on which there is 600 ft. of apex in one place, 360 ft. in another, and remarks further that "if the halo is to be included in the vein, and geologically it should be, this vein then reaches now and did reach all the surfaces to which apical facts are referable. It has, therefore, along its crest and extending above the anticlinal axis of the united main quartz bodies, a condition of things that may well serve as a terminal edge under the many peculiar circumstances and facts of the case."

(2) That the vein is one of rolling type or habit, and that other similar 'anticlines' are found in it which might likewise be looked upon as having apices. As to this theory, the Judge finds that "the vein is very irregular in size and very much distorted and broken, but it is almost free from rolls, having only two worthy of notice, one easily accounted for as a phenomenon of junction with the Fraction vein, and the other as a result of a number of small faults lying close together."

(3) That the strike of the vein or veins (which the plaintiffs claimed to be but one vein, and in which view they were supported by the findings of the Court) is not easterly and westerly, but northerly and southerly, and hence the true direction of its dip is neither north nor south, but to the east. On this point the Court finds that: "Much time and attention was given to the question of strike. As a matter of common sense rather than technical mathematics the strike of the vein as a whole is easterly and westerly, and the strike of its two slopes, assumed for the purpose to be separate veins, is as claimed by the West End." It is almost incredible that two opposing sets of geologists and engineers could differ so radically as to the direction of strike of such a large and well developed structural feature.

The questions of law which were decided in favor of the West End have already been referred to, and the learned Judge concludes as follows:

"If the conclusion reached herein seems revolutionary, that from the apex or apices of one vein extra-lateral rights flow downward across both of its side-lines, attention should be given to words of former Chief Justice Beatty of Nevada:



CROSS-SECTION OF SO-CALLED ANTICLINE.

"'We are willing to admit that cases may arise to which it will be difficult to apply the law; but this only proves that such cases escaped the foresight of Congress, or that although they foresaw the possibility of such cases occurring, they considered the possibility so remote as not to afford a reason for departing from the simplicity of the plan they chose to adopt.'

"It is easy to realize that the condition described in this opinion is one that escaped the foresight of Congress and is also exceedingly remote from the simplicity of the plan they chose to adopt; yet the law must be applied to it.* * *

"This branch of the case is decided in favor of the defendant corporation. That is to say, the West End Consolidated Mining Company is the owner of the ore-bodies in dispute."

This case, like many others, may be appealed; and the present decision may be only the first of many yet to be rendered over the facts here so briefly sketched. Indeed, it is often many years before the final word is said and all doubts as to the final outcome dispelled. In view of such perplexities, is it any wonder that mining men are clamoring for a more rational and easily solved mineral-land law?

CONCENTRATES

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Silver sulphide only, and no metallic silver, is formed by the reaction between cupric sulphide and silver nitrate, the equation for this reaction being $CuS + 4AgNO_3 = Ag_2S + 2Ag + 2Cu(NO_3)_2$.

Thermo-elements, if they are to yield accurate readings of temperature, must frequently be re-calibrated by determination of their electromotive force at a series of fixed points and subsequent interpolation.

Underground charges at the Franklin mine, Michigan, in 1914, were as follows: sinking, $4.36 per foot; rising, $6.342 per foot; driving, $5.158 per foot; crosscutting, $4.873 per foot; and stoping, $4.866 per fathom.

Antimony is too brittle for use alone, but it is a valuable component of many alloys, more particularly with tin and lead, such as pewter, babbitt, and type-metal. It is employed in the manufacture of cartridge cases and shrapnel shot.

The Stokes method for determining pyrite and marcasite, alone or in mixtures, depends on the estimation of the iron dissolved when the finely ground and purified sulphide is treated with a boiling standard solution of ferric alum.

Reverberatory furnaces at Anaconda have increased in size until the new ones are to have hearths 25 by 144 ft. They will be heated by pulverized coal. In the converter department a 25 by 175-ft. furnace will be built. It will be used in cleaning converter slag.

Analyses of water and sediments from springs at Sulphur Springs, Arkansas, and microscopic study of sediments, indicate that sulphides of iron, zinc, copper, and lead are carried in solution, and that iron sulphides, especially, are being deposited in both amorphous and crystalline states where the waters come to the surface.

Transportation of supplies for the Oriental Consolidated mines in Korea has been nearly paralyzed for a time on account of the foot and mouth disease raging among the Korean bulls. The epidemic is a new one in this country, and the bulls are dying very fast. The authorities are applying quarantine to all infected and suspected localities, and no freight can be moved by bulls or cows. Owing to this the price of rice has gone up 25% in one week, as the rice now has to be brought in on ponies.

Amalgamated plates are not used on dredges, as the violent scouring action to which they would there be subjected would carry away the amalgam. A small amount of quicksilver is generally used in the riffles. The latest method is to re-grind in a Hardinge mill with mercury the black sand caught in Neill jigs or in the riffles to recover the gold which it contains.

The influence of nickel on aluminum bears considerable resemblance to that of copper. It increases the yield point and tensile strength with the simultaneous diminution of elongation and reduction of area. It increases specific gravity, hardness, and rate of corrosion in both fresh and sea-water. And decreases electrical conductivity and resistance to alternating stress.

Nitrogen has four main uses: as an agricultural fertilizer, as nitric acid and derivatives therefrom, as ammonia, and in dyes and various other chemical compounds. Measured in the quantity of contained nitrogen, and in view of the restricted opportunities in the United States for immediately developing the chemical and dye industries on a large scale, bearing decisively on atmospheric nitrogen fixation processes only the three first-mentioned uses need be considered, namely, for crop fertilizer, for nitric acid and its derivatives, and for ammonia as such.

Certain water analyses show peculiar properties, according to the U. S. Geological Survey. A pamphlet containing 203 water analyses has been issued. They were made in the chemical laboratory of the Survey. Most of these analyses have already been published, but many of the original reports are out of print, and the data are therefore obtainable with difficulty. A number of the waters analyzed are commonplace in character, but some are most unusual, if not unique. The Devil's

Inkpot, for example, in Yellowstone park, is essentially a solution of ammonium sulphate; waters of Sulphur Bank, California, are rich in borates; while the Shoal Creek springs, Missouri, contain a remarkable proportion of zinc.

GOLD in the Nickel Plate mine, Hedley, British Columbia, occurs usually with arsenopyrite in brecciated or crushed zones of highly metamorphosed sedimentary rocks, between white basic igneous rocks and contact metamorphic deposits. The richest ore does not occur at the contact, but from 6 to 10 ft. away, in the zone of greatest crushing. The profitable ore-shoots so far developed occur near the white gabbro intrusions only. No large orebodies have been found near the diorite, although it forms 70% of the igneous intrusives in the whole district, and there is no diorite occurring near the Nickel Plate orebodies.

MOLYBDENUM has been detected in two basaltic lavas from Hawaii. Its presence in these basalts reopens the question of its occurrence, since it was thought to be confined entirely to the more silicious rocks. Tests were accordingly made on a trachyte obsidian from Hawaii, on some sodic, and especially on some nephelite-bearing igneous rocks from other localities. From these it would appear that the presence of molybdenum is not correlated with high soda or potash content. Except for its well-known tendency to occur in the more silicious rocks, it therefore seems to be influenced by regional rather than by the general chemical characters.

MORE ACCIDENTS occur on cloudy days than on fair days. More workmen are injured, and more seriously injured, in poorly-lighted work-shops than when working in well-lighted places. It is therefore clear that, all else being equal, the well-lighted work place is the safest work place. It has also proved true that where an adequate supply of natural light is brought into service, men work more safely and cheerfully than where the best artificial light is employed. It should therefore always be the aim, both through proper building construction and through continuous cleanliness, to admit ample daylight into the workshop during the working period.

WHEN CERTAIN GRADES OF CYANAMID are melted with common salt, the free graphite in the original material is combined with the calcium cyanamid forming cyanide. A transformation of over 90% nitrogen efficiency is obtained. The resulting product contains approximately 25% KCN equivalent. This material, which can be prepared so as to deliver it into the hands of the consumer at about two-thirds the present price of high-grade cyanides, requires solution in water and filtration. Both operations are easy. The filtrate can be used in the place of cyanide for the extraction of precious metals. Large-scale experiments have been tried in various cyanide works throughout the world. In every case it has proved to be identical in behavior with regular cyanide, showing the same extraction efficiencies. The lower price at which this material can be delivered to the consumer more than takes care of the simple extra dissolving and filtering operations incident to its use. There should be, therefore, a large field for this material supplanting the more expensive, high-grade cyanides.

STANDARD TERMS used in air-lift pumping are as follows: (1) Static head: normal water-level when not pumping, measured from surface or top of well casing. (2) Drop: point to which the water-level drops below the static head while being pumped. (3) Pumping head: level of water when pumping as compared to ground surface or top of well-casing. Static head + drop = pumping head. (4) Elevation: point above the ground surface or top of well-casing to which water is raised. (5) Total lift: distance water is elevated, from level when pumping, to point of discharge, at an elevation, and includes: elevation + static head + drop = total lift. (6) Lift: distance the water is elevated from level when pumping to point of discharge at surface, and includes: static head + drop = lift (or pumping head). (7) Submergence: distance below the pumping head at which the air picks up the water. (8) 100 per cent: the vertical distance the air travels with the water from point introduced to point discharged, and includes: total lift or lift + submergence = 100 per cent. (9) Starting submergence: distance below static head at which the air picks up the water and includes: drop + submergence = starting submergence.

GRAPHITIC OR CARBONACEOUS SCHIST of the West African mines precipitates gold from cyanide solutions. This has been determined by numerous experiments, according to W. R. Feldtmann. The maximum amount which the schist will precipitate is roughly proportional to the percentage of carbon which the sample of schist contains. The finishing or 'load point' is fairly sharply defined. In general, where a maximum load point was aimed at, it amounted to from 4 to 7 oz. gold per ton of schist. That the cessation of precipitation represents a load point of the schist, and not a change in the action of the solution due to contact with the schist, is shown by experiments which proved that the precipitation is limited only by the amount of the precipitating agent contained in the schist on which the auriferous cyanide solution is allowed to act. He summarized his conclusions as follows: (1) It has been demonstrated that the graphitic schists of West Africa precipitate gold from auriferous cyanide solution in a manner that is, in all important respects, analogous to the action of charcoal under like conditions. (2) The gold is precipitated on the charcoal (and on the schist) not as metal but as a compound, possibly a carbonyl aurocyanide. (3) The gold compound is decomposed and the gold dissolved to a considerable extent by alkaline-sulphide solutions (judging by the results of a large number of tests, the re-solution is effected rather more easily from the schist than from charcoal).

Idaho Minerals at the Exposition

In an area of 49 by 61 ft., the state of Idaho has displayed about 250 samples of ores in the Palace of Mines and Metallurgy at the Exposition. A large piece of dressed sandstone stands at the main entrance to the booth. At the back is a reproduction of the Sawtooth mountains. This is 15 ft. high, 16 ft. deep, and 60 ft. long. At the base of this is a series of cross-sections showing the veins, fault systems, and geological features of the principal mines of the Coeur d'Alene region. Benches, tables, and small stands are placed to show the specimens.

In 1914 over 350 producers in Idaho yielded $1,286,459 gold, 13,621,123 oz. silver, 5,178,000 lb. copper, 345,334,106 lb. lead, and 49,230,000 lb. zinc, valued at $24,976,906, from about 2,500,000 tons of ore. In 1913 the Coeur d'Alene returned 2,039,030 tons, worth $17,670,083. Net profits totaled $4,773,287. The state's total to date is $342,000,000.

It is impossible to mention all the exhibits, but the following list is well distributed over the various counties and the metals produced:

Lead-Silver. A bench 60 ft. long and 4 ft. wide contains Shoshone County ores. The Bunker Hill, Hecla, Hercules, Hunter, Success, and Tamarack companies have specimens of country rock, outcrops, ores, and mill products. Among the latter are the mill feed, jig, Wilfley table, and vanner products, oil flotation, and Wyman acid flotation concentrate of the Federal company. The Stewart also has a complete display from its mill. On the small stands mentioned are pieces of ore weighing from 350 to 1100 lb. each. These are from the large properties. In the 'Mine' near the Idaho booth, the Bunker Hill & Sullivan company has a reproduction of part of its mine. In it is a good deal of ore, an electric locomotive, ore-cars, and the 'safety-first' sign at the portal of the Kellogg tunnel.

Zinc. Several mines sent zinc ores. The ore that attracts most attention is that from the Interstate-Callahan. Besides various level ores, there is one piece weighing 3860 lb. This is from a depth of 1200 ft. Mill products are also shown.

Copper. These ores were sent by mines in several counties. One bench contains samples from prospects and productive properties. Shoshone county produced ore from the Snowstorm at Larson; malachite, azurite, black and red oxide, and sulphide from the Empire at Mackay, copper-gold from the Clearwater; 3.3% chalcopyrite from the Bullion; and chalcopyrite, glance, and native copper from the Castle Rock in the Placer Center district. Lemhi county sent copper-nickel from the Gray Eagle in the Black Bird district; also copper-nickel-cobalt from the Uncle Sam. In Custer county is the well known Lost Packer mine. On account of its situation on Lone creek it can only be worked for a few weeks in the summer. Supplies and coke are taken in, and a vigorous smelting campaign takes place. Rich ore is treated. The matte is sent to smelters in Utah. The specimens shown contain 15% copper, 1¾ oz. gold, and 5 oz. silver per ton. From the Leopard and Parallel mines in Copper Basin, and the Silver Bell at Bayhorse are copper-gold ores. Malachite, bornite, and chalcopyrite are mined from the Mountain Queen in the Seven Devils district of Adams county.

Lead. Among these ores are the following: a large block of lead carbonate from the Hercules. It contains iron, cerussite, sulphide, and native silver. The Pittsburgh-Idaho at Gilmore shows lead carbonate assaying 37% lead and 15 oz. silver. That from the Latest Out contains 34% lead, 18 oz. silver, and 10% iron. The Wilbert company, operating in the Dome district of Blaine county, exhibits dense, fine, steel galena containing 38% lead and 9 oz. silver; also mill products.

Gold. Three large and one small table are loaded with country-rock, and low and high-grade ores. The Queen of the Hills sent ore and mill products from the Wood River district, Blaine county. From Quartzburg, Boise county, the Gold Hill & Iowa Mines Co. shows ore and Lane mill products. On a separate stand is a 62-lb. specimen from the Martha vein of the Gilmore Mining Co.'s Allie mine, Lemhi county. The gold is in an ore containing 49% iron oxide, and 5% silica, and occurs as flakes on the iron. Several rich shipments have been sent to Salt Lake City. A miscellaneous lot includes gold ore from the Liberty Bell, at Buffalo Hump, McKinley at Lucile, Buckhorn and Independence at Golden, Franklin and Coeur d'Alene at Ten-Mile, all in Idaho county, and Musgrove and Edmund in Lemhi county.

Rare Minerals. An interesting display of these is made. It includes antimony, nickel, cobalt, molybdenite, wolfram, and hübnerite.

There is also coal, mica, gypsum, limestone, shale, volcanic ash, cement, sand-lime brick, phosphates, and iron ore. The last is from a new deposit at Iron Mountain, Washington county. It contains 56.64 to 64.3% iron, and 6.6 to 17.93% of silica. It is estimated that 3,000,000 tons is available.

The report of the Bunker Hill & Sullivan Mining & Concentrating Co. for 1914 is just to hand, and as this great property is mentioned in the above notes, an abstract of the report should be of interest.

In his brief remarks, the manager, Stanly A. Easton, states that production was well maintained, and development of new ore was highly satisfactory throughout the year. Ore reserves blocked out are as follows; Stemwinder, 27,782 tons; Sullivan, 775,499 tons; and Bunker Hill, 2,904,990 tons, a total of 3,708,271 tons. The Kellogg shaft was completed to No. 14 level, 1000 ft. vertically below the Kellogg (mill adit) tunnel. Station and ore-pockets were finished. Electric pumping equipment was installed. Cross-cutting to the orebodies in two directions is under way. These shoots should be opened on this level early in the spring. Development on No. 13 level was continued, and resulted in disclosing plenty of good ore. In the suit with the Stewart company the court upheld the previous decision in favor of the Bunker Hill company. The value of the ore wrongfully extracted has yet to be recovered. The Sierra Nevada and Caledonia companies paid substantial dividends to the Bunker Hill company. Experimental work resulted in further benefits in the mill. Certain electro-chemical processes promise to increase the recovery of lead, silver, and zinc from mill residue. Prices received for lead and silver were the lowest in 16 years, and below the average of 30 years. The earned surplus available for dividends was $1,017,829, out of which $981,000 was distributed.

The balance of the report is best shown in the following table:

Mine development, feet	2,754
Cost per foot ($8.849 in 1913)	$10.768
Ore mined, tons	440,819
Cost per ton ($2.225 in 1913)	$1.98
Electric haulage of men, ore, and supplies, per ton	0.56
Hoisting 350,651 tons, per ton	0.049
Pumping charges, per ton	0.045
General mine expense, per ton	0.405
Underground improvements, per ton	0.041
Ore crushed and concentrated, tons	440,819
Cost per ton	$0.39
Concentrate shipped, tons	56,731
Lead production, pounds	70,663,236
Silver production, ounces	1,161,324
Value of metals	$3,362,499
Operating profit	949,987
Dividends paid	981,000

The balance at the end of 1913 was $2,880,203, and $3,245,475 at the end of 1914. Dividends from other companies and increased book valuations accounted for the increase.

The output to date is as follows: ore mined, 6,462,867 tons; gross value, $60,231,542; net smelter returns, $35,820,939; operating profit, $19,817,614; and dividends paid, $15,710,250.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

HOUGHTON, MICHIGAN

Optimism in the Copper Country.—Construction.—Development of Small Properties.—College of Mines.—Mayflower, Quincy, and Ahmeek in 1914.

There is nothing but good news to report from the Michigan copper district. When we read that the mines and mills at Butte and other Western copper centres are returning to nearly normal production, we are glad of it. We also realize and appreciate more fully how much better off Michigan has been during the last six months than the Western districts. For several months the mines at Keweenaw point have been operating at full capacity. At present all the large producers are operating above normal. Nearly 15,000 men are now employed here. Beginning May 1, all the surface and underground men of the Calumet & Hecla and subsidiary companies will receive a wage increase of 10%. Over 7000 employees will receive the increase, which means a return to the high wages paid before the curtailment of last fall. Several weeks ago the Quincy Mining Co. advanced wages. On May 1 another raise will become effective. This second increase will place the wage schedule where it was last August.

The resumption of construction work, which was interrupted last fall, is noticeable. At the Victoria a shaft will be sunk close to the present working shaft to increase production and lower hoisting costs. A new steel ore-house will be erected at No. 5 shaft of the Mohawk. No. 3 shaft of the Osceola will soon be ready for resumption of mining. No. 3 shaft of the North Kearsarge will probably start during May. No. 3 and 4 shafts at the Ahmeek are being overhauled for regular work.

According to the superintendent of the Mayflower company, G. S. Goodale, all work during the year ended February 12, 1915, was confined to further exploration of the property by diamond-drilling. Two machines worked in holes 35 to 41, inclusive, drilling a total of 10,304 ft. No. 39 reached a depth of 2087 ft. No. 34 and 37 make up a transverse vertical section across the formations, and in the restricted area investigated indicate a disorganized condition of the strata due to faulting and crushing. Other holes showed similar disturbance. No. 41, down 1747 ft., is in uniformly firm and undisturbed ground, but not deep enough to prove the mineralized formation. Expenditure on prospecting amounted to $26,483. Including assessment No. 2 of $74,379, the revenue was $91,406. Cash at the end of 1914 amounted to $62,985.

While the present high price of copper means large profits to the large producers and increased wages to the employees, it also means a great deal to the smaller exploration companies and prospects. Anxious to take advantage of the present market, these will accelerate development as much as possible. The Hancock mine is gradually increasing its shipments to the Franklin mill. More men are being employed underground. The Houghton Copper Co. is building a railroad spur to permit shipment of ore from its stockpile of several thousand tons. At the Lake mine preparations are being made to unwater the shafts, to resume exploratory and mining work. Franklin and New Arcadian will probably commence shipments to the Franklin mill early in May. Algomah will probably resume underground work in a week or so. Wyandot will resume mining as soon as the mine is pumped out. Exploration will be resumed at the Onondaga property directly. The recently discovered New Arcadian lode continues across the New Baltic property. Since it has been found that this lode improves in character as it approaches the New Baltic, the latter company will expose the lode at different points by pits and cross-trenches.

Regular work of the Quincy company in 1914 was hampered by the effects of the miners' strike of 1913, heavy airblasts around No. 2 and 6 shafts, and the copper market. Results were as follows:

	1914.	1913.
Copper sold, pounds	22,612,460	18,161,575
Revenue from copper	$2,041,992	$1,900,365
Revenue from silver	12,630	20,832
Net profit after paying operation, construction, accident account, etc.	205,505	76,161
Dividends	55,000	412,500
Surplus at end of year	897,533	746,938

The people of the copper country are much pleased with the announcement of Governor Ferris that he will reappoint

MOHAWK No. 1 SHAFT-HOUSE.

to the Michigan College of Mines board of control William Kelley, of Vulcan, president of the board, and James MacNaughton, of Calumet. The good of the institution, rather than politics, influenced the appointments.

The Ahmeek Mining company reports as follows for 1914: At No. 1 shaft all development shows 'rock' of average value. Mules are used for tramming on No. 8, 12, and 14 levels, with satisfactory results. No. 2 shaft area has proved of average quality. New equipment at No. 3 and 4 was started on June 1.

	1914.	1913.	1912.
'Rock' stamped, tons	590,519	383,689	652,260
Copper sold, pounds	13,634,605	9,044,166	15,950,492
Average price, cents per lb.	13.08	15.42	16.61
Cost, cents per lb	9.71	13.30	7.85
Total revenue	$1,787,436	$1,433,695	$2,757,576
Profit	462,644	176,919	1,465,396
Dividends	200,000	850,000	1,100,000
Surplus at end of year	968,771	706,128	1,379,209

At the stamp-mill the low-pressure steam-turbine is in place and nearly connected. All floors and foundations are finished for two stamps, also 46 Wilfley tables and 12 Hardinge mills have been installed.

The Calumet & Hecla company will pay $15 per share on June 18. On March 18, $5 was distributed. Total to date, $1294 per share.

CRIPPLE CREEK, COLORADO

Gold Output.—Milling Suit.—Trail Mine.—Bull Hill Air-Compressor.—Mary McKinney and Sitting Bull.

The following is the output of the Cripple Creek district for the month of May, as reported by the various mill and smelter managers:

	Tons.	Average value.	Total value.
Golden Cycle	28,000	$23.00	$644,000
Portland (Colorado City mill)	11,300	19.50	220,350
Smelters	5,500	55.00	302,500
Portland (Cripple Creek mill)	18,900	3.00	55,900
Independence	9,680	3.08	29,814
Ajax	1,225	6.12	7,497
Neville	2,100	3.20	6,720
Dante	900	2.50	2,250
Wild Horse	550	3.50	1,925
Total	78,155	$16.26	$1,270,956

The new Golden Cycle Mining & Reduction Co. has been threatened with suit by the old United States Reduction & Refining Co. This revives some interesting milling history. The latter company owned and operated the Standard plant at Colorado City at the time the Golden Cycle mill started in 1907. It had in addition, two idle plants, the Philadelphia at Colorado City, and the Union at Florence. Later an agreement was made with the Golden Cycle; in consequence the Standard plant was closed in 1912. The present suit is really between different factions of the United States company to prevent the sale of the properties, and the Golden Cycle is interested only in so far as its agreement with the United States company is concerned. A. E. Carlton, president of the Golden Cycle is quoted as follows in a recent interview: "Under the arrangement made by John T. Milliken, the controlling factor in the Golden Cycle until a few weeks ago the latter agreed to take care of the interest on the bonds of the United States company in return for the turning over to him of the ore contracts it held. That agreement terminated last December, but was renewed, and will continue until the same date next year. The Golden Cycle, independently of most of these contracts, has the sole right to treat the ores from the greater number of the mines of the Cripple Creek district. In addition to having contracts, many of the properties are interested in the Cycle mill, such as the Vindicator, Elkton, Cresson, and the United Gold Mines, and naturally would wish to participate in the profits of the milling as well as the mining of their ores. We are prepared to pay enough in addition to the contract obligation to let the owners of the United States company have the junk value of the three mills, plus the amount of the contract. In other words, we will be willing to buy these plants up to a cost to us of $350,000 at a receiver's sale. We can realize, perhaps $125,000 on them as junk, but we will have fulfilled our obligations. If the stockholders and the bondholders cannot agree, or if either of them believe that their interests are not protected, they can fight it out and we will carry out the promises made by Mr. Milliken. There is no hope at present for anyone to get into the milling business on a profitable scale, in view of our ore-contracts, so that ends the situation so far as the mills are concerned. We will not raise the prices nor attempt in any way to gouge the miners. Such a step would be adverse to the mines which feed us their products." To the casual observer it would seem as though the extravagant promises made in various prospectuses sent broadcast by those having the Golden Cycle stock to sell have killed the 'golden goose,' and that those mines which do not participate in the profits from the Golden Cycle mill may demand lower rates rather than allow their more favored neighbors to make 2% per month from treating their ores. Indeed, rather than having things as tightly sewed up as Mr. Carlton seems to think, we may yet see another mill war such as made earlier days so interesting. Indeed, to many of us, the time seems ripe for a local custom-mill to treat ores under $10 per ton in the district itself, thereby saving $1 per ton for a 40-mile down-hill haul to the valley.

The new development by Eby & Co. at the Trail continues to open well. A two-car shipment returned a settlement of $40 per ton. More men are employed and a good future is promised for this lease.

The large air-compressor at the Logan shaft, which has supplied air to many of the smaller mines on Bull hill and vicinity, was stopped on May 1. This plant, together with its extensive pipe-lines, was first operated by the Woods Investment Co. of the early days. It enabled many a small prospect to be operated in the easiest and cheapest manner by means of air-drills. It was profitable for the Woods people, and later for the Western Investment Co. Recently the plant was taken over by a local syndicate which has found that the expense of operating by steam is prohibitive. They have made arrangements to substitute electric power. This change is the probable reason for the closing down of the plant. It also means the loss of at least 200 tons per day in the production of the district.

The Maryana Leasing Co., controlling ground on the No. 8 level down in the Mary McKinney, has men at development. A drift is being driven to connect with a winze sunk from the old Anaconda adit. As soon as connection is made the company will have a large block of ground ready for active work. New electrically-driven machinery is being placed on the Mary McKinney to enable the company to extend work to a greater depth.

The Hondo Mining Co. operating the Sitting Bull claims situated in the gulch between the Portland and the Golden Cycle, has recently found good ore at 200 ft. Some shipments have been made. This is good ground which has been idle since the early days when $150,000 was taken from a single shoot at the 100-ft. level. We expect to hear great things from this property now that systematic development has been undertaken.

PLATTEVILLE, WISCONSIN

Zinc, Lead, and Pyrite Markets in April.—District Outputs.

In April the Wisconsin zinc-lead districts developed many extraordinary features. These tended to bring about higher metal prices. Zinc ore was higher than ever before. The beginning of the month saw recessions in both the quotations for metal and ore, the latter coming in for more pronounced cuts. What was lost by metal was quickly recovered. By the end of the month the highest prices ever recorded were attained.

Diligent inquiry among leading representatives of smelter interests brought out conflicting statements regarding stocks of metal and ore at smelters. All agreed that metal stocks were low. On the question of ore, some contended that stocks were large, others that this was not so. One large zinc-ore producer admitted that buyers were solicitous in securing contract arrangements whereby they might obtain the output of mines on flat-rate agreements. Mining men were as one in expressing dissatisfaction with quotations prevailing for zinc ore during April. In this dissatisfaction is already discovered one of the greatest disturbing factors in the status of markets on both metal and ore in the immediate future. It requires no discriminating intelligence to observe that the production of zinc ore is below the theoretical maximum output expected by smelters, who have already oversold on the current production, and later when it becomes imperative to secure the necessary supplies to meet contracts based upon future delivery, there will be a scramble for ore with more attractive offerings. Miners are not at all anxious to become parties to the execution of contract agreements. While every

possible expedient is being met to secure a largely enhanced output of zinc ore, none reveal any desire to go beyond a normal output at present. The district is actually making lighter deliveries than were reported during the long period of depression that existed in the zinc-ore markets prior to the first advances recorded in August 1914. Zinc ore prices opened strong at the beginning of April at from $60 to $70 per ton of 60% metal content. This gradually declined to as low as $54. At the end of the month prices recovered to $65 to $75, with premium separator product going as high as $78 per ton. The bulk of the shipments for the month came from smelter-controlled properties. There was little open-market offering. The zinc-ore reserve at all points in the district on the last day of the month was in excess of 5000 tons.

Lead ore showed little improvement. Fair gains were made in the price of pig lead, but the demand for lead ore showed apathy on the part of buyers. Ore that was cleared sold at about $54 per ton, 80% metal content.

Producers of iron pyrite faced an indifferent market. Scarcely any demand came until the last week, when the demand improved. Prices, especially on fines, became better, and by-product cleared from all of the separating plants.

Carbonate of zinc-ore producers received treatment from buying interests noted for its 'refined cruelty,' ore going to the highest figures ever published, yet not a pound of product was sampled and no deliveries were made, although thousands of tons were ready for sale and shipment.

The following ore deliveries were reported by districts:

Districts.	Zinc, pounds.	Lead, pounds.	Pyrite, pounds.
Benton	12,016,000	825,140	1,282,000
Galena	5,252,000	90,000	.....
Hazel Green	4,326,000	.....	.....
Livingston	3,928,000	.....	.....
Cuba	2,680,000	.....	854,000
Platteville	1,718,000	.....	.....
Linden	1,930,000	146,040	878,000
Mifflin	970,000	296,090	.....
Mineral Point	114,000	.....	.....
Highland	56,000	.....	.....
Total	32,990,000	1,357,270	3,014,000

Sales were made to the following buying concerns: Mineral Point Zinc Works, 8085 tons; National Separating Works, Cuba, 1609 tons; Matthiesen & Hegeler Zinc Works, 1534 tons; Illinois Zinc Co., 1013 tons; Campbell Magnetic Separating Co., Cuba, 739 tons; Grasselli Chemical Co., 636 tons; Empire Roasters, Platteville, 1881 tons; Linden Separating Works, 413 tons; and American Metals Co., 317 tons.

Shipments of lead ore were the best for any single month shown in years. About 1000 tons more are held in reserve. Pyrite was secured at the electro-static separating plants.

MIAMI, ARIZONA

MAGMA MINE DEVELOPMENT.—SUPERIOR & BOSTON, IRON CAP, ARIZONA COMMERCIAL, COLD-GOODWIN.

The Magma company, which operates the richest copper mine of its size in Arizona, has almost finished construction that has been underway for several months. A narrow-gauge railroad 30.20 miles long has been built between the Magma (town of Superior) and Webster station on the Southern Pacific, nine miles northwest of Florence. Another shaft from the 1200-ft. level to the surface is almost completed. An electric hoist of 2000-ft. capacity has been ordered. Development has shown that the formation or the quartz-porphyry dike that carries the ore-shoots has changed its dip twice below the 800-ft. level. For 800 ft. it followed an inclination of about 65 or 70° to the north. From 800 to 1000 ft. it is vertical. Diamond-drilling shows its dip from the latter level to 1200 ft. to be about 65° to the south, or just the reverse of its dip nearer the surface. A notable change in mineralization is apparent at 1000 ft. While the copper content of the shoots is the same, the gold value has quadrupled, being $1.60 per ton on the lower level, compared with 40c. per ton nearer the surface. On the lower level zinc also occurs in large quantity, it being in separate shoots from the copper. Neither the copper nor zinc ores contains the slightest amount of the other metal. The zinc ore contains about 20 oz. silver. At present the Magma mill is handling about 150 tons of ore daily. The crude (hand-sorted) averages about 2% copper, concentrate the same. The apparent low copper percentage of the concentrate is due to the unusually high iron content of the latter, fully 15%. The manner of mining the Magma during the past few months has resulted in a high saving in cost of timber, as well as increased efficiency. The general manager, Mr. Browning, was able to improve on the usual method of back filling in the stopes by the vertical position of the vein between the 800 and 1000-ft. levels to such an extent that all handling of the ore in the stope after breaking has been obviated. This has been accomplished by laying planks on the floor of the stopes at a steep inclination from each side toward the centre of the stope, thus forcing the ore when broken to run by gravity into the chute connecting with the drift below. The Magma mine and mill now employ between 150 and 175 men. Because of the number of men now employed in development nearing completion it is not probable that the advent of railroad transportation will mean any immediate increase of the working force at the property. Thirty men are employed on shaft work alone. The shaft has been cut mainly by a series of rises and winzes and is completed to within about 30 ft. of the surface. It is being cut with two compartments, but will be widened immediately to three when the present rise is through to the surface, some time in the latter part of May. The new hoist will be a Nordberg electric with rope pull of 10,500 lb., lifting speed of 750 ft. per minute, and 2000-ft. capacity balance drums. It will be equipped with automatic contact-control, insuring increase of power by regular cycle precluding any danger of sudden rush of current. In the beginning the hoist will be operated with a skip on one side and cage on the other, but two skips will eventually be used. The hoist will be 25 by 12 ft. over all. The hoist room is 17 by 40 ft. in the clear. The railroad will be turned over to the Magma company as soon as cessation of wet weather permits of thorough surfacing, probably the last week in May.

About 100 men are now employed at the Superior & Boston mine. Shipments of copper ore go to the El Paso smelter.

The Iron Cap is shipping four cars of ore per week to the El Paso smelter. It averages 10% copper. High-grade ore, containing between 25 and 30% copper, is being stored, about 200 tons already being in the stock-pile. In January and February the mine and its equipment were thoroughly overhauled. The collar of the shaft was concreted to a depth of 18 ft. and the shaft was re-timbered 200 ft. below the concrete.

The Arizona Commercial's future improves with development. Three stopes in sulphide ore on the 1300-ft. and one on the 1200-ft. level are being worked, and 175 tons of ore is being shipped daily to the Old Dominion smelter. The pumping plant is lifting about 450,000 gal. of water per day from the 1400-ft. level to 1200-ft., whence it flows to the Old Dominion shaft. The connecting drift at the 1200-ft. level between the Old Dominion and Arizona Commercial shafts is 8000 ft. long. It was finished last October by the latter. It is used solely for draining the Arizona Commercial and for ventilation.

The Cold-Goodwin, one of the best of the Miami district's prospects, has resumed development as the result of the increased price of copper. In the bottom of the shaft (500 ft.), the chalcopyrite ore that has been found from the surface is changing to chalcocite, a change which almost invariably results in increase of the sulphide zone throughout this district.

KALGOORLIE, WESTERN AUSTRALIA

ZINC-SHEET AND STEEL MANUFACTURE.—MOUNTAIN QUEEN AND QUEEN OF THE HILLS.—YUANMI COMPANY.—SONS OF GWALIA.—HORSE-SHOE.—GREAT BOULDER.—EDNA MAY.

Every country has had to accommodate itself to new conditions resulting from the War. Australia is no exception. One instance is the zinc-shaving supply for cyanide plants. The Broken Hill Proprietary Co.'s spelter contains only 1.2% lead and 0.06% iron. It is suitable for rolling into sheets. Arrangements have been made with Hoskins and Co., of Lithgow, New South Wales, to roll this spelter into sheets. From these shaving is cut. In normal times imported zinc-shaving in Australia costs $30 per ton more than is charged for spelter. The cost of Australian shaving is considerably more. The War has also caused the Broken Hill Proprietary to combine with the North and South companies in increasing the Port Pirie smelting works. The first-named company has also made a start at Newcastle, in making steel rails. The Commonwealth government has already contracted with it for the supply of 12,500 tons. The total is approximately $550,000, or $44 per ton. Delivery will commence in July. It will be the first delivery of steel rails actually made in Australia. The New South Wales, Victorian, and South Australian governments are said to have also ordered rails from the company. Other proposed lines will help the new works.

The plant of the Mountain Queen at Southern Cross is being dismantled; it is to be transferred to the Queen of the Hills mine at Meekatharra. The latter is owned by the Lake View & Aroya Exploration Co., which also holds two-thirds of the Mountain Queen shares. The ore-shoot in the latter mine became so poor and refractory in the sulphide zone as to be unprofitable. The Mountain Queen is equipped with a double No. 1 Holman pneumatic stamp-mill, a 4 by 16-ft. tube-mill, and vacuum-filter. These were driven by a 224-hp. Kynock gas-engine, and Commonwealth down-draught wood-gas generators burning ordinary 5 to 6-ft. wood. This mill has, during the last year, been treating 3000 tons monthly, yielding $30,000, with a profit of $10,000. This is more than sufficient to pay the annual dividend of 12c. per share or $90,000 per year on the Lake View & Oroya Exploration Co.'s shares. As the plant on the Mountain Queen is a duplicate of the Queen of the Hills plant, its installation at the latter will about double the revenue and profit. Probably, the dividend also, if last year's average can be maintained.

In December 1914 G. C. Klug, manager for Bewick, Moreing & Co., acquired for the Yuanmi company 401 acres at Wardanrie in the Yalgoo district on the Murchison. At that time the prospectors had a shaft down 100 ft. and a winze 30 ft. below that level. At the bottom of this winze a drift 31 ft. long was in ore 65 in. wide for a distance of 31 ft. It assayed $17.52 per ton. Cross-cuts show the full width of the lode to be 102 in., assaying $12.72 per ton. The lode is opening so well that it is proposed thoroughly to develop the mine. The plant at the worked-out Black Range mine will be moved to the new property.

The announcement that a winze below the No. 20 level of the Sons of Gwalia mine, sunk to 23 ft. at a point 930 ft. south, has averaged $20 per ton over a width of 72 in. is good so far as it goes. However, in the drift at the same level, the ore-shoot from 915 ft. to 991 ft. was also in ore averaging $20 per ton. The winze was put down in a rich part, and proves its continuity at depth.

The cutting of No. 4 lode in the Golden Horse-Shoe at 2480 ft., 300 ft. south of the main shaft, and 700 ft. south of the Ivanhoe boundary, is hopeful. This is the most southerly point that this ore-shoot has been located in the deeper levels of the Horse-Shoe since it returned from Great Boulder ground. This ore, which averages $8.16 per ton over a width of 96 in., is 800 ft. from the Chaffers boundary. As it is cut out in the Great Boulder long before reaching the Main Reef, now owned by Chaffers, the outlook does not look promising for the latter. Before being absorbed by Chaffers the Main Reef company drove on this lode at a depth of 2261 ft. It was only worth $3.34 per ton for the width of the drive and a length of 102 feet.

In addition to trenching on the surface, Richard Hamilton, manager of the Great Boulder mine, has had a diamond-drill hole put in from the 1100, 1250, 1450, 1650, and 2200-ft. levels of the Boulder Perseverance mine to test the two lodes on the eastern boundary of the claim. In various trenches on the surface the ore assayed as follows: $2.04 for 24 in., $10 for 60 in., $12.24 for 60 in., and $53.04 for 30 in. In the boreholes the assays varied a good deal, but ore assaying $18.36 for 12 in., $10.20 for 84 in., $24.48 for 30 in., and $8.64 for 72 in. was cut at various points. As all these discoveries were made well within 200 ft. of the Perseverance boundary, and 500 ft. east of the Great Boulder's main drifts, cross-cutting from the Perseverance would soon prove whether the new lodes are worth serious attention.

The boom in the Edna May group shares continues in Melbourne, Victoria. Any mine with the prefix of Edna May in its title 'goes off like hot cakes,' if put on the market. The Battler and Battler Extended with the Edna May prefix, situated 4½ miles northwest of the Edna May, only containing 'leaders' 9 to 12 in. wide, were put on the market at $1.25. They immediately moved to $1.75. The Empress, which is on the Murchison 300 miles north, is included in the group. As it was sponsored by the same people, it is quoted at $6, and has touched $7.20 for a $2.40 share, on which $1.75 only is paid up. This mine is depleted down to 250 ft. A shaft has to be sunk below that level before any ore can be obtained, far less tested. The Edna May directors are evidently afraid to sink. The shaft, from July to the end of January, was left at a depth of 240 ft. It reached 268 ft. by the end of February; no sinking has been done since. Ore reserves on November 1, 1911, were only 52,000 tons, or 18 months' supply.

PETROGRAD, RUSSIA

MONGOLIA PRACTICALLY WITHDRAWN AS A FIELD FOR MINING.

A statement has just been issued dealing with Mongolian gold mining that will be a surprise to Russians and foreigners. It will be remembered that on the strength of Russia's political interference with China's protectorate over Mongolia, resulting in the emancipation and practically the independence of the latter, great hopes were raised of Mongolia becoming not only a large source of supply in respect to corn and cattle, but also a fine field for industrial enterprise, particularly gold mining. The statement refers to the great interest in gold that existed about the time of the emancipation. It is well known that high hopes were raised at Petrograd at the time on the strength of the alleged gold deposits of that country. It will be also remembered, for what reason was never clearly expressed, that not long ago the Russian government issued a warning to all whom it might concern, that anyone committing himself to mining operations in Mongolia must do so entirely at his own risk, the relations between that country and China were such as to make it inconvenient for Russia to grant such protection as the preceding political events might have made industrialists think she was competent to afford. Whether it was the issue of this Government warning that constituted the cold douche on mining in Mongolian gold, and certainly it was well calculated to discourage the foreigner from going too deep into it, or whether for some other reason, it would appear that the Mongolian gold industry as a field for outside enterprise has been relegated to a more or less distant future.

Two large deposits of copper pyrite have been found 18 miles from Elisavetpol, according to a recent consular report. Sulphur content is from 48 to 53 per cent.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

The U. S. Geological Survey is dispatching 12 parties to Alaska to continue the systematic surveys and investigations that have been in progress for the past 18 years. Of these parties three will be sent to southeastern Alaska, including Juneau and Ketchikan, one into upper Chitina region, one to Port Valdez, two will work in the Turnagain Arm-Knik region, one will make investigations in the Yukon-Tanana region, and two in the Ruby-Kuskokwim region, and another will traverse the little-known area lying between the Ruby district and the Tanana river. One party will be engaged in general investigations in different parts of the Territory. These parties will sail from Seattle during May so as to take full advantage of the field season. All the men needed for the work have been engaged, and the purchase of horses, supplies, and equipment is well under way.

The second session of the Territorial Legislature is finished. Among the laws passed are the following relating to mining: workman's compensation act, general mining law, law providing for the assessment of unpatented claims, an 8-hour law for placers, and new mine inspection act.

Chisana

It is reported in Cordova that A. McGuire has discovered rich ground in Dry gulch, near Johnson creek. He has bonded the claims to F. Hoffman and J. J. Finnigan. A shaft cut bedrock at 142 feet.

Fairbanks

Three claim-owners started sluicing on Ester creek on April 11. Others on Cleary, Chatanika, and Fairbanks creeks were then preparing for the season.

Juneau

According to P. R. Bradley, superintendent of the Alaska Juneau company, an 8000-ton mill will be erected near the present small plant. It will be designed by George Bradley, who planned the Gastineau mill. A large wharf is to be built. A hydro-electric plant will also be constructed. In the suit of the Alaska Juneau *v.* Ebner company, involving water-rights on Gold creek, the verdict was in favor of the defendant, upholding its claim of prior rights.

ARIZONA

Cochise County

At the Douglas smelter of the Copper Queen company 16 roasting furnaces are working. Six are treating sulphide ore from Bisbee. Large shipments of concentrate from the Moctezuma mill at Nacozari, Sonora, will keep the plant busy for some time.

Mohave County

(Special Correspondence.)—Bullion shipments from the Tom Reed-Gold Road district during April were valued at $165,000, against $160,000 in March. Ore treated in April totaled 14,500 tons, compared with 14,000 tons in the previous month. Rich ore from the winze down 125 ft. below the Tom Reed 950-ft. level helped to swell the returns.——The cross-cut at 565 ft. in the United Eastern has cut the vein. It is similar to the shoot at 460 feet.

Oatman, May 4.

At 1075 ft. in the Tom Reed mine the vein is 18 ft. wide, several feet more than where opened last week.——After a heavy flow of water had subsided at 300 ft. in the Pittsburgh, it was found that a good vein was exposed in the face of the drift.——It is reported that the Arizona Southwestern Copper Co. has been financed. The mine will be unwatered. The new shaft is to be sunk to 500 ft. Good lead ore has been opened at 200 feet.

Yavapai County

Encouraging developments are reported from the Black Chief Copper Co.'s property in the Black Hills district. Some new machinery was recently bought in Prescott by the manager, J. M. Sullivan.——Good progress is being made in erecting the Grey Eagle Reduction Co.'s plant. It will have a capacity of 50 tons per day.

CALIFORNIA

Amador County

Eighty stamps continue to crush ore at the South Eureka mine near Sutter Creek.——An assessment of 5c. per share has been levied by the Treasure Mining Co. Its property is between the Bunker Hill and Fremont mines at Amador City. ——Some good ore has been opened at 1200 ft. in the Keystone. C. R. Dow is superintendent.——Suit has been started by the Original Amador company to quiet title to several claims within the limits of Amador City. Residents have erected houses on them.——It is reported that by means of an assessment of 50c. per share, E. Green has secured a controlling interest in the old Eureka Consolidated.

Calaveras County

About 24 in. of rich ore has been cut at 100 ft. in the Ford mine near San Andreas. J. C. Benson is in charge.

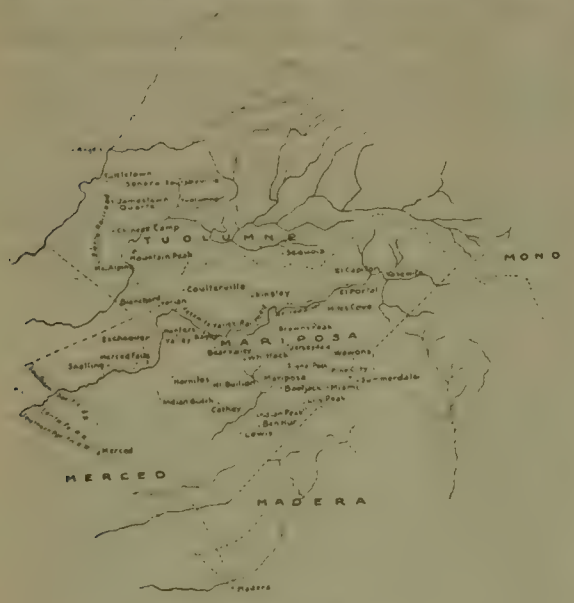
Eldorado County

A rotary gravel mill has been installed at the Rising Hope mine near Placerville. It will treat up to 125 tons per day.

Mariposa County

(Special Correspondence.)—Morison, Flagel, and Quinn, lessees at the Pine Tree mine, owned by the Mariposa Commercial Mining Co., crushed 22 tons last week for $127 per ton.——The Mountain Queen company has been incorporated by San Francisco and Oakland people. They acquired the Sunshine claims. This property is fairly well opened and equipped. Three hundred tons milled returned $12.50 per ton by amalgamation. Concentrate assayed $300 per ton.——The Colorado Mining Co., controlled by Judkins, Weston, and Dearborn, on Sacton creek, crushed 80 tons, yielding $21 per ton. The shaft is down 250 ft. The vein averages 4½ ft. wide. Ten stamps are worked.——Teal, Oleson, and associates have purchased the old Washington claims of 300-acres of patented ground.——Carroll Bros. and others are erecting a 5-stamp mill on the Stud Horse Flat property, on the Merced river, two miles below Bagby.——The Little Wonder claims have been re-bonded to Los Angeles people, miners are driving an adit to cut the vein.——The Rival and Sweetwater property is being developed with 30 men. A mill test of 62 tons from a 4-ft. vein on the Rival mine is said to have been satisfactory. A hoist and steam pump are to be installed.——Worthington, Skelton & Co., of Jerseydale, are developing the Gevil Gulch claim. Machinery is to be purchased soon.——The Clearing House mine on Merced river is being operated in charge of George Egenhoff.——The Red Banks mine, two miles below Bagby, is being developed. The compressor will be moved from the Crown Lead mine. Machine-drills are to be installed. ——The Virginia mine near Bagby has resumed operations under direction of Mr. Pounding, of Oakland. A 10-stamp mill

is crushing good ore.——Charles E. Paine, of Mariposa, has discovered a deposit of molybdenite on the Summit.——L. P. Helmer had 60 tons of ore treated at the Austin mill. It yielded $14 per ton by amalgamation. This ore is from the old Persia mine on Sacton creek.——Mrs. Jennie E. Diven, of



MAP OF MARIPOSA COUNTY.

Oakland, has secured 62½% interest in the Buckingham Mountain claims. About 2000-ft. of development has been done. Prospects are good. A large mill is one of the possibilities.

Mariposa, May 3.

Nevada County

The Golden Center company has issued its authorized capital of 25,000 shares at $2 each. Mining is being carried on under part of the residential district of Grass Valley.——The Major mine near Nevada City is being re-opened.

The H. B. Nichols property of 60 acres, west of Grass Valley, has been sold to J. B. Preble, of Seattle. A shaft is down 150 ft. Both quartz and gravel occur.

Placer County

Work has been resumed at the old Black Oak mine near Wermar. Buildings and machinery are to be erected.——Improvements at the Eureka and Banner mines near Auburn consist of a large pump, compressor, and roller mill.——The Marigold Gold Mining Co. is to purchase five claims of the Hines Gilbert-Gold Mining Co. The price is said to be $140,000, paid in installments.

Sierra County

Work is to be resumed at the Oriental mine below Alleghany. The main adit is over 4000 ft. long. The property has been closed for 10 years. W. B. Pearson, of the Plumbago mine, will also take charge of the Oriental.——The Alhambra and Extension have been bonded. Good ore has been developed in them.

COLORADO

San Juan County

The Silver Lake mill is being re-modeled. Oil-flotation machines are being installed.——The Gold King mill is busy. The Louis Bastian flotation machine is doing good work.——The North Star mine is to be sampled and developed.——Mining has been resumed at the Mayflower.——The Shenandoah and Trilby have been leased.

IDAHO

Blaine County

In March the Wilbert company in the Dome district, 25 miles east of Arco, mined 209 tons of ore. Of this, 159 tons, averaging 6.56 oz. silver and 57.14% lead, was shipped to Utah. The profit was $1279. High-grade ore is coming from the 500-ft. level. When the mill starts it will produce 1500 tons of concentrate per month.

Lemhi County

(Special Correspondence.)—A two years' lease on the Italian mine has been secured by M. H. Phillips and John M. South. Work has been started. A 30-stamp mill driven by water-power is ready for crushing ore.——The concentrating plant at the Copper Queen mine is to be started on low-grade dump ore. T. E. Lynch is owner. Gas-engines are used for power.

Leesburg, May 3.

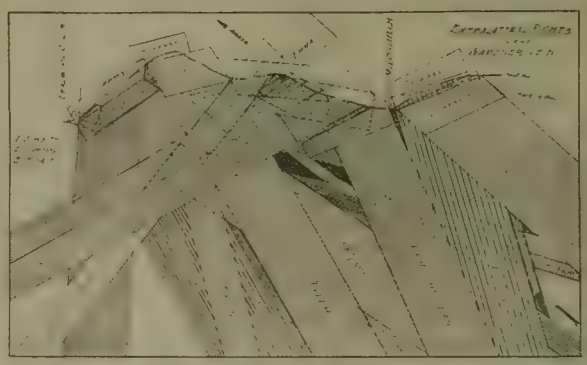
Shoshone County

On May 5 the Caledonia company distributed 2c. per share, equal to $52,100. The total for the current year is $260,500. In March the mine produced 3164 tons of ore. Of this, 529 tons was shipped. The mill treated 2517 tons. Mining cost $1.84 per ton, milling, 81.2c. The ore and concentrate contained 47,664 lb. copper, 1,080,240 lb. lead, and 97,484 oz. silver, valued at $100,599.

The Stewart mine is producing 500 tons of ore daily. Owing to the Hypotheek ore being not suitable for treatment in the Stewart mill, the proposed milling contract has been abandoned.

The Idora Mining Co.'s mill on Beaver creek is to be remodeled to treat 150 to 200 tons per day. It has been leased to Gus Ehrenberg, of Spokane, for 30 months. The Tuscumbia mine will supply ore for the plant.

The application of the apex law at Wardner is discussed by Fred T. Greene, of Butte, Montana, in a paper to be presented at the September meeting of the A. I. M. E. at San Francisco. He states that there are many storm-centres of



apex litigation in the Rocky Mountains. Not the least of them is the Wardner camp, where such litigation has been almost continuous since 1892, and the end is not yet. In their decisions, the Courts have accepted the claims of the litigants that the 'Wardner vein' is a broad zone varying from 250 to 500 ft. in width at the surface. This is the simplest theory which could have been advanced, and probably decreased, rather than augmented, the number of contests; in fact, every one of the claim-owners seemed to feel that the greatest advantage would accrue to him if this theory were adhered to. The dominant structural feature of the Wardner vein is a persistent fault, striking north 40° west, dipping about 40° to the southwest, and called the 'Wardner footwall.' Twenty years of litigation established the rights of the following claims as shown in the accompanying plan: Lackawanna, Sullivan, Bunker Hill, Stemwinder, Emma, Last Chance, Tyler, King Fraction, Viola, San Carlos. Rights of

the Phil Sheridan, Republican Fraction, Cheyenne, Lincoln, Sims Fraction, and Overlap remained to be determined.

MICHIGAN

The U. S. Bureau of Mines rescue-car which has its headquarters at Ironwood, is at Houghton for instruction. Miners and College of Mines students will see proper demonstrations of first-aid work.

HOUGHTON COUNTY (THE COPPER COUNTRY)

(Special Correspondence.)—The stamp-mill at the White Pine mine commenced regular work with two shifts on May 3. 'Rock' is being taken chiefly from stock-piles. Nothing is known yet as to the amount of copper extracted. Plans are now under way for the erection of collar-houses, a supply-house, change-houses, and shops.

Houghton, May 7.

So much copper is being sent by water to the East that the Mutual Transport line has put on another boat. The *Rhoades* last week took on 2700 tons of metal at Lake Linden.

Large numbers of mostly unskilled men are crowding the copper district, and the unemployed situation is causing some alarm. The local papers are warning men not to come to the region.

Mining and milling is to be resumed at the Winona. This will give employment to about 400 men. Lessees' time is up on June 1.

The report of the Winona Copper Co. for 1914 shows that in August the mine was closed, but in October a tributing arrangement was made with 35 of the best of the former employees to work certain stopes on No. 3, 4, and 5 levels from No. 3 shaft. This has resulted satisfactorily for all concerned. The last three years compare as follows:

	1914.	1913.	1912.
'Rock' stamped, tons	123,339	120,806	181,148
Copper produced, pounds	1,352,085	1,448,737	2,307,237
Revenue from copper	$109,797	$223,299	$376,219
Total revenue, including balance from 1913 and assessment	368,069	419,235	541,128
Total expenditure	275,421	344,727	479,094
Balance	92,648	74,508	62,034

On June 12 the Calumet & Hecla company and subsidiaries will distribute a bonus of over $500,000 among nearly 10,000 employees.

MISSOURI-KANSAS-OKLAHOMA

On May 4 the H. L. & S. concentrating mill at Lawton, Kansas, disappeared. This was due to a cave-in of some ground. The loss is about $10,000.——The Carmean & Squires company has resumed work at the No. 4 mine, near Webb City, Missouri. Ore occurs at 180 feet. The mill has a capacity of 250 tons.——The Gennessee company is prospecting at Duenweg. One drill has found ore at 180 to 192 ft. It assays 11.36% blende.——Development at the Wilson property at Duenweg is satisfactory.

MONTANA

FERGUS COUNTY

(Special Correspondence.)—Development in the North Moccasin mine of the Barnes-King Development Co. in the past few months has disclosed a large body of rich ore, apparently extending under the townsite of Kendall. This shoot was found at a depth of 700 ft. This is deeper than any work that has been done in this district. The Barnes-King output in March was $56,000. The outlook is bright. One hundred men are at present employed by the Barnes-King company at Kendall.

The old Kendall mine adjoins the North Moccasin property. It was closed in November 1912, when the known orebodies were worked out. Its shaft, however, was only 500 ft. deep. The orebody now being developed by the Barnes-King has been opened as far as the Kendall property line on the 700-ft. level. Among the possibilities of the future is that the Kendall will be reopened, and the shaft sunk 200 ft. deeper to mine this orebody. The Kendall has produced a total of several million dollars in gold. It has distributed $1,505,000 in dividends, paying $30,000 out of surplus as late as July 1914. It has a well equipped power-plant and cyanide mill. It is to be hoped that the owners will soon re-open their mine and carry on exploration at depth.

The Fergus Oil & Gas Co. has been reorganized. J. H. P. Gauss is the new president, Louis Blodgett, secretary, and Mr. Murray, treasurer. Active exploration will start soon.

Another oil company has been incorporated by Moore capitalists for $100,000, of which $80,000 has been issued. They will prospect for oil near Moore.

Lewistown, April 28.

SILVERBOW COUNTY

Work is to be resumed at the Mountain View mine of the Anaconda company. About 750 men will be employed. The normal output of ore is between 1200 and 1500 tons per day. On account of the court decision on the Alice mine, mentioned in the *Press* last week, work has been suspended.

The report of the North Butte company for the first quarter of 1915 states that from the treatment of 54,570 tons of dry ore and 15½ tons of precipitate the yield was 3,358,325 lb. copper, 179,569 oz. silver, and 181 oz. gold. The mine was worked at from 50 to 60% normal capacity. Good developments resulted from work on the Edith May and Snowball veins. The Granite Mountain shaft is ready for work.

NEVADA

ESMERALDA COUNTY

The U. S. District Court at Seattle has appointed Carl Johnson, of Seattle, permanent receiver for the Goldfield Merger Mines Co. Suits are to be commenced against directors for alleged abandonment and loss of property, especially the Velvet claims sold to the Jumbo Extension.

HUMBOLDT COUNTY

According to Frank Margrave, superintendent of the Nevada Packard Mines Co., preliminary arrangements have been made for construction of a 75 to 100-ton mill. A pipe-line is being laid. Electric power will be secured from the line supplying the other mill at Rochester.

LINCOLN COUNTY

Tests on Amalgamated Pioche ore, by the General Engineering Co. of Salt Lake City, show that water concentration and flotation will make a good recovery. When treatment is started this system will be used.

NYE COUNTY

Seven mines at Tonopah produced 9871 tons of ore worth $203,638 during the first week of May.——The Extension company has declared a dividend of 10c. per share.——There are 13 sets of lessees working in the old workings of the Midway. Forty dollar ore is being broken between the 1070 and 1170-ft. levels of the Merger. It is stated that the company may acquire one of the mills at Tonopah. The report of the Tonopah Extension Mining Co. for the year ended March 31, 1915, has been issued. Development amounted to 12,651 ft., making 84,421 ft. to date. Cross-cutting will soon be started at 1350 ft. No estimate of ore reserves is possible, but the increase in treatment capacity from 150 to 250 tons per day was justified. All underground costs were $5.191 per ton. The mill treated 71,882 tons averaging 28.13 oz. silver and 0.264 oz. gold per ton. From the sale of 1,790,032 oz. silver and 17,585 oz. gold was received $1,285,508. Treatment cost $3.753 per ton. Marketing charges were 45c. per ton. The net profit was $590,165. New equipment consisted of a Nordberg hoist, Chicago pneumatic air-compressor, electric-haulage plant in the mine, 10 stamps, two tube-mills, Dorr apparatus, Rockwell furnaces, and a high-pressure water system.

UTAH

Beaver County

A hoist and compressor are to be installed at the Lenora mine. The superintendent, A. C. Nebeker, has been in Salt Lake City for this purpose.

Juab County

Ore shipments from the Tintic district last week totaled 149 cars.——Nothing but high-grade zinc ore, 36 to 40%, will be received by smelters, hence there is considerable dissatisfaction among producers. A good deal of the zinc ore sent out this year contains under 30% metal. The quantity of the higher grade is limited.——The Mammoth and A. S. & R. companies have arranged a new smelting contract.

Salt Lake County

(Special Correspondence.)—The Alta and Big Cottonwood districts continue to hold the interest recently aroused. The stocks are all strong on the Exchange, and there is great activity in the mining-claim market. The Wasatch Mines Co. has furnished the latest excitement by finding the continuation of the old No. 5 orebody on the other side of a fault. This shoot is on the Braine fissure and the Cardiff contact. So far as developed, it is 7 ft. wide, and averages $40 per ton. They are about to commence shipments. The company had started a drainage adit some time ago, but abandoned the project. This is now to be resumed.——The Alta Con. has so far blocked out an orebody 440 ft. long, 2 ft. wide, and 100 ft. high, at a depth of 500 ft. The average value of the ore is $40 per ton.——The Emma Copper Co., whose claims adjoin the old Emma mine of international reputation and historic interest, is prospecting for the continuation of the Emma orebody, which has yielded about $11,000,000.

Salt Lake City, May 7.

A couple of days later than the above was written, 5 ft. of ore was cut in a rise in the Flagstaff ground of the Wasatch company, 4000 ft. from the portal of the Tom Moore or Flagstaff adit. As soon as the roads are in good condition teams will start hauling ore.——The Michigan-Utah company will resume work in June.

The report of the Utah Copper Co. for 1914 contains the following information:

The area of mining claims is now 738 acres. Other land covers 6031 acres. Development in the Boston claims totaled 9030 ft. Drilling amounted to 8920 ft. The totals of development and drilling to the end of the year were 448,533 and 46,391 ft., respectively. Underground development cost 0.88c. per ton of ore mined. Adding drill work, the total was 1.7c. per ton, against 2.34c. in 1913. This was charged to operation. The ore area is now 226.3 acres. The average thickness is 465 ft. Reserves are estimated at 342,500,000 tons averaging 1.45% copper. An additional quantity probably lies under these reserves. The average thickness of capping is 115 ft. During the year 5,708,836 cu. yd. of overburden was removed. To date the total is 27,834,043 cu. yd. Of the ore mined, 98.27% was by steam-shovels, the balance from underground. Cost of shovel work was 30.96c. per ton. Underground work cost 78.45c. The combined average cost was 32.32c. per ton.

The Magna plant treated 4,461,461 tons of ore. The Arthur did not work after August 6. It handled 2,008,705 tons. The year's tonnage was 1,049,226 tons less than in 1913. The metal market was responsible for the curtailment. The average grade was 1.425%. Average extraction was 66.04%, an increase of 2.09%. The cost of milling was 35.36c. per ton, a reduction of 1.3 cents.

The Bingham & Garfield railway carried 5,902,196 tons of freight. Of this, 4,829,877 tons was ore, 100,466 tons coming from other mines at Bingham. Transport cost 27.82c. per ton.

The smelter produced 121,779,401 lb. copper, compared with 119,939,809 lb. in 1913.

Financial results were as follows: Total operating costs were 95.5c. per ton, a decrease of 2.1c. The revenue from 115,690,445 lb. copper, 34,729 oz. gold, and 325,352 oz. silver, etc., was $16,222,456. The operating profit was $5,992,163. Income from dividends, interest, etc., less other interest, made available $8,678,491. Dividends totaled $4,827,885. Depreciation amounted to $523,851. The surplus at the end of 1913 was $9,708,653, and at the end of 1914, $13,035,409.

Summit County

The Big Four Exploration Co. is to erect a 250-ton plant to treat a dump of 800,000 tons of tailing at Atkinson, seven miles north of Park City. Kirk and Leavell designed the plant. The tailing contains gold, silver, lead, and zinc, and averages $5 per ton. It is an accumulation from the various mills at Park City.

The Park City Mills Co.'s plant has resumed work. It has a capacity of 35 tons per day. Recent experiments by Messrs. Holt and Dern have shown that over 85% recovery can be guaranteed.

Tooele County

(Special Correspondence.)—The Tooele smelter of the International company is now treating 1000 tons of lead ore and 600 tons of copper ore per day. There are five lead furnaces in operation. There have been several changes made in the staff positions, all in the nature of promotions.

Salt Lake City, May 7.

CANADA

Alberta

It is just a year since the oil boom commenced at Calgary. Oil was found in the Dingman well, 40 miles southwest of the town. About 450 companies were organized with a capital of $500,000,000. At the present time about 50 companies are drilling for oil. Five wells have given promising results. The oil-bearing area is estimated at two by three and a half miles.

A party of miners, in charge of J. C. Vanlicke, who represents United States and Canadian capital, has gone to examine the Fond du Lac district. This area is at the east end of Lake Athabasca, about 600 miles north of Calgary. Reports of a silver discovery were made last year, but nothing has been heard of the place lately.

MEXICO

Hidalgo

In March the Santa Gertrudis mine made a profit of $32,600 from 13,917 tons of ore treated.

San Luis Potosi

An antimony smelter is being erected in the city of San Luis Potosi, according to a consular report of April 2. It will be ready to start when mining and transportation conditions permit the ore-supply to be shipped and the product exported. The machinery, which is American, is now ready for installation. It is expected that the plant will employ 150 men. The capacity is to be 3000 tons per annum of refined star antimony. The product will be shipped to the United States. This will be the first and only smelter in Mexico producing refined antimony for the market. It is owned by American capital. Ores will come from its own properties in San Luis Potosi and Queretaro.

The only antimony smelter heretofore operating in Mexico is situated at Wadley, a small station on the National Railway, 102 miles north of San Luis Potosi. The Wadley smelter is not equipped for finishing the product. It has exported its product to England for further refining. The Wadley plant was erected about 14 years ago. A large part of its ore came from the Catorce district. Antimony has been found in many places in Mexico, especially in Durango, Sonora, and Oaxaca. Relatively small quantities of ore have been shipped to the United States for smelting. The Catorce deposits have been the best producers for the last 20 years. The ores are rich. Antimony appears in many ores treated at the lead smelter at San Luis Potosi. Its presence is deleterious.

PERSONAL

W. C. Maisch is at Petrograd.

Albert Burch is at Goldfield.

R. T. Tustin, of Chicago, is in Idaho.

T. H. Oxnam was at El Paso during the week.

Mark L. Requa has returned from New York.

Oscar H. Hershey is returning from Kellogg, Idaho.

J. V. N. Dorr will be in Denver during the month of May.

Philip L. Foster and A. F. Main have been at Telluride, Colorado.

Charles Butters has moved his New York office to 120 Broadway.

W. J. Loring left San Francisco on May 9 for New York, on his way to Chile.

E. H. Leslie was married on April 10 at Pittsburgh to Miss Mathilda G. Shrom.

H. W. Hardinge has left New York for an extended trip to the West and Alaska.

A. M. Yonge has returned to Costa Rica as superintendent of the Mina La Union.

E. M. Hamilton sailed on May 8 from Liverpool to New York, on his way to California.

Henry S. Munroe, professor of mining in the Columbia School of Mines, retires on June 30.

William Wraith is general manager for the International Smelting & Refining Co., at Tooele, Utah.

Charles P. Beresford, manager of the Prestea mine, West Africa, has been visiting Cobalt, Ontario.

R. Gilman Brown is leaving London on a visit of inspection to the Kyshtim and Ridder mines in Siberia.

F. L. Bosqui is returning from Johannesburg to London, where he will open an office as metallurgical engineer.

H. D. McCaskey succeeds Edward W. Parker as chief of the Division of Mineral Resources in the Geological Survey.

Lloyd B. Smith, of the Associated Geological Engineers, has returned to Pittsburgh from the oil-fields of Mexico and Central America.

Arthur Bennetts of the Quincy mine has been appointed head mining captain of the Mass, to succeed the late W. J. Ninness.

Will H. Coghill has removed his laboratory from Chicago to El Paso, Texas, where he will continue the testing of ores at 3705 Hueco street.

Edward W. Parker has resigned from the U. S. Geological Survey to accept an appointment as the head of a bureau to be formed by the anthracite mining companies.

Edgar H. Gould, for several years efficiency engineer at the North and South Kearsarge mines of the Osceola Consolidated, has been appointed underground superintendent at the White Pine.

William R. Appleby, David T. Day, Bradley Stoughton, Harry H. Stoek, George S. Rice, and Joseph W. Richards are in attendance at the Panama-Pacific Exposition as jurors in the Mining Department.

Frederic Keffer, for 17 years connected as manager and consulting engineer, with the British Columbia Copper Co., has formed a partnership with Henry Johns, for 15 years superintendent of the same company's mines. Their office is at Spokane.

Scott Turner is a survivor from the *Lusitania* disaster. C. T. Brodrick is among those lost; a graduate of Harvard, he had done excellent work lately as a mining geologist in Siberia and more recently he had given his services to the Belgian Relief Commission. Another victim of the disaster is Lindon Bates, Jr., a Yale graduate, a promising young man, and the son of the chairman of the Belgian Relief Commission at New York.

Lead Production in 1914

By C. E. Siebenthal.

(Advance statement, U. S. Geological Survey.)

Production of refined primary metal available for consumption, and production of secondary lead.

	1912	1913	1914
Desilverized lead	309,857	301,160	340,397
Soft lead	141,248	131,867	158,219
Desilverized soft lead	29,789	29,433	43,506
Total production of refined primary lead	480,894	462,460	542,122
Production of antimonial lead	13,552	14,667	16,668
Supply:			
Stock in bonded warehouses Jan. 1.	4,481	10,492	5,310
Imports—			
For consumption	14,146	11,980	7,386
For warehouse	69,414	45,165	20,952
Production from domestic ores	392,517	411,878	512,794

[1] Lead content of bullion for 1907–1909 estimated on the basis of average lead content of imports of base bullion in 1910.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, May 12.

Antimony	35 —35¾
Electrolytic copper	19¼—19½
Pig lead	4.45—5.45
Quicksilver (flask)	$75.00
Spelter	13¾—14
Tin	45 —46½
Zinc-dust, 100-kg. zinc-lined cases	20

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, May 13.—Copper is quiet but strong; lead is dull but firmer in the West; zinc is scarce for immediate delivery.

COPPER

Prices of electrolytic in New York, in cents per pound.

Exports from the United States during the week ended April 24 totaled 14,585,358 lb., valued at $2,158,807. Of this, 4,936,972 lb. went to England, 4,543,639 lb. to France, 3,899,930 lb. to Italy, 583,384 lb to Norway, 391,277 lb. to Scotland, and 105,024 lb. to Spain. Imports amounted to 7,008,085 lb. of all kinds, worth $820,700.

The American Smelting & Refining Co. will pay a dividend of 1¾% on preferred and 1% on common stock on June 1. Copper Range is producing at the rate of 35,000,000 lb. per year.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

June	56.43	....	Dec.	49.27	....

The above quotations indicate a steady market. London advises a good undertone. American sellers have been shy. The upward movement last week was due to a better enquiry from Indian Bazaars. China exchanges have not reflected the firmness of the silver market so much as might have been expected, but there is nothing to suggest that the higher quotation would attract selling from that quarter. European purchases have been small. Up to April 22 exports from London to the East totaled £1,684,000, against £2,346,500 in that period of 1915. The decrease is equal to about 6,650,000 ounces.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

May	33.29	....	Nov.	33.51	....
June	30.72	....	Dec.	33.60	....

The tin market is quiet at 41c. per pound. A Consular report from Chile states that the Campañia Estañifera de Llallaqua has been organized at Santiago with a capital of $243,325, to erect a tin smelter at Arica or Mejillones.

In 1914 the value of the secondary metals, exclusive of gold, silver, platinum, iron, and steel, recovered in the United States was $57,039,706, according to J. P. Dunlop, of the U. S. Geological Survey. This is a decrease from 1913 of $15,746,321, the secondary metals recovered in that year being valued at $72,786,027.

The term 'secondary' does not imply that these metals, which are recovered from scrap metal, sweepings, skimmings, drosses, etc., are of inferior quality, but is used to distinguish them from 'primary metals,' which are derived from ore. Secondary metal included 127,882 tons copper, 61,062 tons lead, 71,642 tons zinc, 12,447 tons tin, and 4522 tons aluminum. These are equal to 22, 11, and 20% of the first three primary metals produced, and 26% of the tin imported.

Eastern Metal Market

New York, May 7

The demand for copper has eased off but prices are well maintained. Tin has been dull and quotations have declined under the influence of cheap Banca tin. Spot spelter is scarce, and prices show a tendency to go higher, although future metal has been more freely offered. Chinese antimony is quoted at 34 to 35c. Fears are entertained for the future supply from China and Japan because of the unsettled conditions in those countries.

COPPER

The demand has been quieter in the past week, but London is strong. Prices here are fully maintained. Electrolytic advanced £1 in London, May 5. The tone here is steady. Most producers are holding to 19c., full terms, equal to 18.87½c., cash, New York, but second hands quote 18.62½c., cash, New York. There is talk of renewed inquiry from abroad for large quantities, but nothing definitely is known. Over 1,000,000 lb. of high-grade Lake sold during the week at 23c. Good grades, for which the claim is made that they will answer every purpose, can be had at 21c. This is considered a fair quotation. Exports in April totaled 16,822 tons, 6147 tons of which went to the United Kingdom and 4499 tons to France. Italy took 2539 tons and Sweden 3318 tons. The contracts for shells and ammunition which have been placed in this country are the cause of feverish activity to erect new plants and extensions to existing ones to house the thousands of machine-tools which have been purchased to turn out the material required in quick time. Thousands of tons of steel rounds have been bought, and as much is being negotiated. As previously pointed out, all this activity has a direct bearing on the metals.

LEAD

The domestic demand continues light. Some weakness has been imparted to the market by the action of a few consumers in offering at concessions metal which they previously had purchased. Small quantities have been sold on a basis of 4.05c. f.o.b. St. Louis. Foreign buying appears to be a little less active. The figures of production of refined primary lead in the United States, as given by the U. S. Geological Survey, show that unprecedented as were the exports of 1914, they were not great enough to offset the increased production of 1914 as compared with 1913. The increase was 79,622 tons or 17.2%. The trade generally regards the figures as showing the cause why lead has not advanced under the war demand proportionately to copper and spelter. New York quotation yesterday was 4.20c. and that at St. Louis 4.07½ cents.

SPELTER

Spot metal is quoted at 14.25 to 14.50c. At the latter price a couple of cars of prime Western were sold May 5, and a car of higher grade went at 15.50c., New York. On May 4, offerings were made on the floor of the New York Metal Exchange of 12.75c. for May delivery, 12.50c. for June, and 12c. for July. No sales resulted. The broker making the offers had 100 tons for each month, and would have disposed of the quantity in lots of 25 tons. He was commissioned to make the offerings, and did not solicit bids. Western makers of galvanized sheets are investigating the market in futures carefully before entering commitments for their product.

TIN

The chief features of the week are the lower price following a freer offering of Banca tin, and the modification of Great Britain's restrictions on trading in the metal. Business has not been active at any time and to this, also, was due the decline in price to 38.50c quoted May 6. England's concession did not do much to help the wholesale dealers, as both they and their customers must continue to file agreements which will satisfy the British consul as to the ultimate destination of the tin they handle. A third form of agreement was adopted which will permit the retailers to do business. The change was brought about by the tin committee of the New York Metal Exchange. The April tin statistics showed that deliveries into consumption in that month were good, amounting to 3200 tons. The total for four months showed a decrease of 3575 tons, as compared with the same period of last year. The arrivals at Atlantic ports totaled 4236 tons and those at Pacific ports, destined for the East, amounted to 1100 tons. It is notable that shipments from the Straits in April were 302 tons larger than in the same month last year. There was afloat yesterday 5140 tons, 725 tons of which was Banca.

ANTIMONY

Hallett's and Cookson's are practically unquotable, although a sale of two casks of Cookson's has been heard of at 40c. Chinese has jumped to 34 and 35c., prices which have been paid. In the week England is reported to have purchased 250 tons in this market. Not only England, but other countries which ordinarily are sellers are now buyers. The political complications in Japan and China are causing fears that that source of supply may be cut off. Stocks of the metal were large up to a few months ago and it has been their absorption by manufacturers providing for the future, coupled with the smaller flow of metal to this country, which has sent prices up. A smelter to produce refined antimony will be started at San Luis Potosi, Mexico, as soon as mining and transportation conditions permit. It is an American-owned company. Notes on this appear in 'The Mining Summary' of this issue of the *Press*.

Exports of metals, April 30 to May 1: copper, 5679 tons; lead, 2992 tons; and spelter, 1219 tons.

Schools and Societies

The UNIVERSITY OF CALIFORNIA held its 52nd commencement on May 12. There were 968 degrees of all classes conferred on graduates. The ceremony took place in the Greek theatre. The total enrollment during the past school year was 8699 students.

The AUSTRALASIAN INSTITUTE OF MINING ENGINEERS spent the second week in March visiting the west coast mining districts of Tasmania. There were 70 members in the party. Mt. Lyell (copper), Zeehan (lead), Mt. Read (zinc-lead), and Mt. Bischoff (tin), were among the places visited. At Queenstown, where the Mt. Lyell mine and smelter is, an interesting four days were spent. Robert C. Sticht is president.

The alumni of the MICHIGAN COLLEGE OF MINES will hold their Panama-Pacific Exposition re-union on September 20 and 21. These dates immediately follow those of the meeting of the A. I. M. E. The college alumni register, an elaborate pigskin-bound, gold-inlaid volume presented by the Chicago M. C. M. Club, has been placed in the Bureau of Mines exhibit in the Palace of Mines and Metallurgy. Wilbur H. Grant, consulting engineer in San Francisco, was the first to register. Milton B. Huston, of Philadelphia, was second. The Board of Control of the college has asked for the cooperation of the faculty and alumni association in arranging for a celebration of the thirtieth anniversay of the college in 1916.

BOOK REVIEWS

STAMP MILLING AND CYANIDING. By Francis Andrew Thomson. P. 285. Ill., charts, index. McGraw-Hill Book Co., Inc., New York, 1915. For sale by the *Mining and Scientific Press*. Price, $3.

This is an excellent little work on a subject which has been covered many times by other writers. One would think that unless something new had been developed there would be hardly any scope for another book. The concise manner in which it has been arranged gives the volume its chance. Strictly speaking it is a compilation. The author, who is at the State College at Pullman, Washington, admits this. He has drawn freely from the leading journals in the United States, and one in England, which devote most of their space to ore treatment. Manufacturers of machinery for this purpose helped illustrate the book by supplying photographs of their products. These combinations resulted in a variety of opinions on processes.

The 15 chapters include the following discussions: characteristics of gold and silver; principles of amalgamation; the stamp-mill and its accessories (a good review); stamp-mill amalgamation; modifications and applications of the stamp-mill (from Gilpin county, Colorado, to the Rand); modified gravity-stamps, steam-stamps, arrastras and pans, centrifugal and edge-runner mills, and tube-mills and ball-mills; comparisons of various mills, that is, work done; history and chemistry of cyaniding; preparations of ores for treatment, from crushing to agitators; dissolving gold and silver; separating solution and pulp; all filters described; precipitation methods; and clean-up and smelting.

Following each chapter is a complete bibliography of the subject, a feature in several recent works, including 'Rand Metallurgical Practice.' A table gives the characteristics of slime-filters in convenient form. The two last chapters deal with the relations and functions of apparatus in gold and silver mills, so here are found flow-sheets of 18 types of mills.

ELECTRIC MINE SIGNALLING INSTALLATIONS. By G. W. Lummis Paterson. P. 196. Ill., index. D. Van Nostrand Co., New York, 1914. For sale by the *Mining and Scientific Press*. Price, $1.50.

This is a practical treatise on the fitting-up and maintenance of electrical-signalling apparatus in mines. The writer is the author of a well known work, 'Management of Dynamos' and others. Save occasional articles in the technical press, little has been published on this subject. The use of electricity for signalling has been more or less used in mines for over 50 years. In recent years it has been a feature, in fact, at large and deep mines, the outputs could hardly be maintained with the old methods of signals. The author illustrates and describes apparatus which experience has shown to give the best results, and shows by plans the best methods of installation and maintenance. Electricians at various mines often devise their own signal systems, resulting in interesting comparisons of efficiency. Turning to the volume under review, we find discussed ringing keys and tappers, bells, alarms, relays, and indicators, generators and primary batteries for mine-signal installations, shaft wiring and signals, and electric engine plane wiring and signals. Most of the diagrams given, especially the shaft arrangements, are of practical use to mine electricians. An appendix contains an abstract of electricity rules enforced in English coal mines. Also U. S. Bureau of Mines regulations. A useful lot of symbols for motors, generators, converters, transformers, switches, signals, and ground connections is given.

COMPANY REPORTS

ALASKA GOLD MINES COMPANY

For some years the preparatory work of this company's subsidiary, the Alaska Gastineau Mining Co., has attracted considerable attention. It is now a gold producer, the first unit of the mill is crushing ore.

The area of claims and land owned, and controlled under option, in the vicinity of Juneau, is approximately 2489 acres. Development in the mine in 1914 amounted to 28,523 ft. Diamond-drilling totaled 6203 ft. To the end of 1914 the total was 53,703 ft. of ordinary work, and 7545 ft. of drilling. Adding the work done previous to that of this company, the openings are over 13 miles. Little was done last year to prove additional ore. Work was mainly to prepare ore for extraction. For the first time it is possible to make a statement regarding ore reserves. The block lying substantially west of No. 2 incline shaft, and above No. 10 level, contains about 21,000,000 tons, fully developed. It averages slightly less than $2 per ton. This estimate does not include ore between No. 1 and 2 shafts, between No. 8 and 5 levels, or any below No. 10 level. But taking all into consideration, there is not less than from 75,000,000 to 100,000,000 tons of a recoverable value of $1.50 per ton. If lower yet profitable ore is included, this quantity would be greatly increased. The accompanying plan shows the condition of the mine at the beginning of 1915. The mill is now crushing about 2000 tons per day. Its ultimate output should be 10,000 tons per day.

The Salmon Creek power scheme is practically finished. When it is, the cost of 6000 hp. per month should not exceed $1000. Another source of power from three creeks is to be developed, work having started. It is valuable for summer power.

The new mill started in February. In March it treated about 40,000 tons. The tailing assayed a trifle over 30c. per ton. This will be reduced later. The heads averaged $1.85 per ton. In June the second unit will be started, the third and fourth about a month later. Concentrate is receiving treatment in a temporary plant. The mill was described in the *Press* of April 17. The report is an excellent one in many ways. All necessary information is given to the shareholders. The large panoramas of the mine, mill, and power-plant give an idea of the large size of the undertaking.

ANACONDA COPPER MINING COMPANY

The extensive ramifications of this company are always a source of interest. Recent financial arrangements have been fully discussed in the *Press*. During 1914 the mines and works operated at 50% capacity from August 1 to the end of the year. Many of the mines were entirely closed. At the present time they are nearly all working full time.

Underground development last year totaled 33.15 miles. The total amount of shaft-sinking was 3460 ft. Shafts at the Mountain Con., Diamond, Steward, and Mountain View were extensively repaired. Development was generally satisfactory, especially in the Leonard, West Colusa, Steward, Original, Tramway, Anaconda, Badger State, and West Gray Rock mines. A tonnage of ore slightly greater than the quantity extracted (3,898,100 tons) was added to the reserves. Eleven main and nine auxiliary hoists were operated by compressed air. Electric locomotives reduced costs underground. Safety-first departments were kept busy. Metal production was as follows:

	Anaconda.	Great Falls.
Ore, etc., treated, including custom ore, tons	3,748,726	488,244
Copper, pounds	188,664,551	35,055,741
Gold, ounces	78,815	20,836
Silver, ounces	7,555,915	758,201

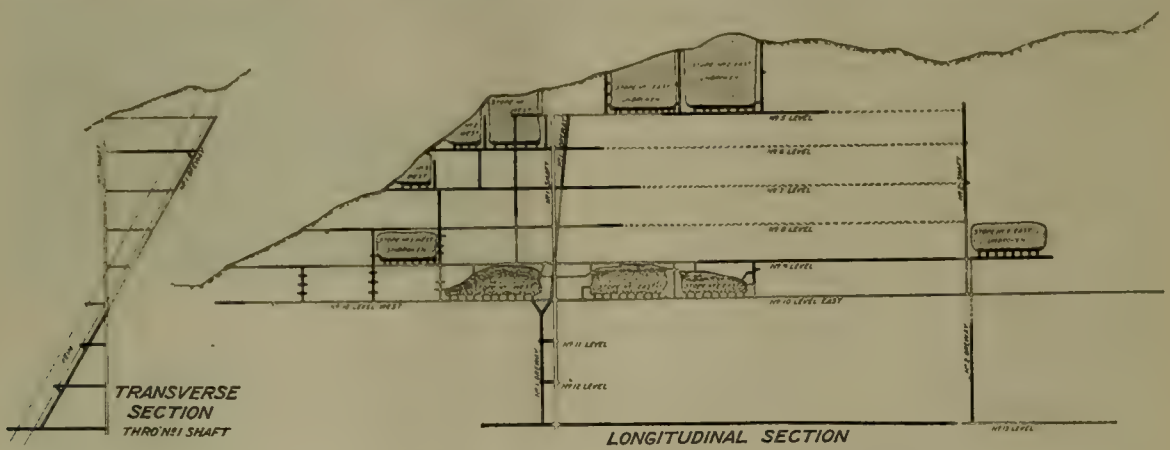
The company's mines contributed 3,768,640 tons of ore, etc., and 205,298,531 lb. copper, 99,651 oz. gold, and 7,221,815 oz. silver.

Financial results were as follows:

Sale of metals	$36,745,559
Royalties, rents, etc.	457,129
Metals on hand at end of 1914	14,330,972
Total income	$51,533,660
Operating expenses	$28,149,316
Metals on hand at beginning of 1914	16,173,788
Balance to profit	7,200,556
Revenue from investments and subsidiaries	2,843,491
Total profit	10,044,047
Dividends paid	9,077,500

The year commenced with a balance of $7,968,971, and ended with $7,681,059. The excess of dividends was therefore drawn from the surplus.

Improvements to cost $6,000,000 are now being made to the plants. These have been mentioned in the *Press*. The April output of 21,800,000 lb. is nearly the normal production.



PERSEVERANCE MINE, JUNEAU. DARK LINES SHOW WORK DONE IN 1914.

New Machines and Devices

Information based on letters and catalogues from manufacturers.

Wood Tank and Pipe at the Exposition

Tanks and pipes made of wood are used extensively in mining operations. Pipes are increasing in favor for power, corrosive and other waters, and other purposes. In the Palace of Mines and Metallurgy at the Panama-Pacific Exposition, the Pacific Tank & Pipe Co., of San Francisco, has an exhibit of unique design. It covers an area of 32 by 36 ft. The booth is built up entirely of wood water-pipes. The two sides and back consist of both 2 to 32-in. machine-banded and 24 to 48-in. individually-banded California redwood and Douglas fir pipe. The pipe is completely formed and ready for actual use.

The ceiling of the booth is covered with filter-cloth, burlap, and cocoa-matting. This material is the same as is used in the bottom of leaching vats in cyaniding.

Near the back is a section of 10-ft. diameter pressure pipe constructed from 4 by 6-in. redwood staves heavily banded with ¾-in. pipe bands and pipe shoes. This pipe rests in two standard saddles similar to those used in regular field work.

Directly in front of the 10-ft. pipe and in the front of the booth is placed a model cyanide leaching plant complete in every detail, with clean-up and refining house, even to the pipes necessary.

On either side of the model plant are the two entrance gates. At the side of each are two 50-ft. model towers with 20,000-gal. tanks, walk-ways, and conical covers; one a model 12-post wood tower with wood deck, wood tank and cover, and the other a 4-post model steel tower, wood deck, wood tank, and wood cover.

Within the booth are shown samples of the different pipe couplings, such as mortise and tenon, wood collars, riveted-steel collars and cast-iron collars for joining the ends of the pipe together. Also a large number of different model patent and plain tanks to be used either for settling, or for Pachuca agitators, and rectangular tanks. All the different iron and brass-pipe fittings used in connection with service connections for municipal water-works or irrigation. Different samples of round and flat hoops, lugs, and shoes, iron-pipe fittings and wood-pipe fittings for acid waters, bottom-discharge doors, zinc lathes, and a complete line of goods manufactured and carried by the firm, fully covering both the tank and pipe work in every field.

Drag-Line Cable-Way Excavator

The drag-line cable-way excavator, while having found a wide application in industries other than mining, is not as well known a device to mining men as it should be.

Sauerman Bros. of Chicago are at the present time introducing their drag-line excavator to the mining world. The excavator is designed for digging sand and gravel, and many other kinds of excavation and stripping work. It can be operated successfully either in wet or dry ground. The machine consists primarily of a bucket and carriage mounted on a slack track-cable. The carriage runs out to the loading point by gravity. The track-cable is slackened to permit the bucket to dig into the material. The machine is operated by a double friction-drum hoist.

Owing to the simplicity of construction and operation, the drag-line excavator will excavate, elevate, convey, and dump the material in one operation. Actual operation shows that material may be handled at a cost of about 3 to 6c. per ton, depending on local conditions. In mining operations the field for this machine would include certain placer deposits, stripping, and open-cuts. The device is not only applicable to pits,

A DRAG-LINE CABLE-WAY EXCAVATOR AT WORK.

but also to hillsides. The accompanying photograph shows the excavator at work. An interesting catalogue is ready for distribution.

Commercial Paragraphs

In 1914 the GENERAL ELECTRIC Co's sales totaled $90,467,691, compared with $106,477,439 in 1913. Like most other concerns in the country there was a decrease in business.

Alberger 'Spirofio' surface condensers (dry vacuum system), and tubular heaters for boiler feed and general service are the subjects of *Bulletin* 12 and 13 of the C. F. BRAUN & Co., of San Francisco. Sectional plans are shown, accompanied by data useful for this apparatus.

A 5 by 12-ft. adjustable quick-discharge tube-mill was recently sold by CHALMERS & WILLIAMS, of Chicago Heights, Illinois, for shipment to India. Catalogues on this firm's modern crushing machinery and the Symons disc-crusher have been received. Several advantages are claimed for the latter. A 5 by 10-ft. mill has also been sold to the Marsh company, Wallace, Idaho.

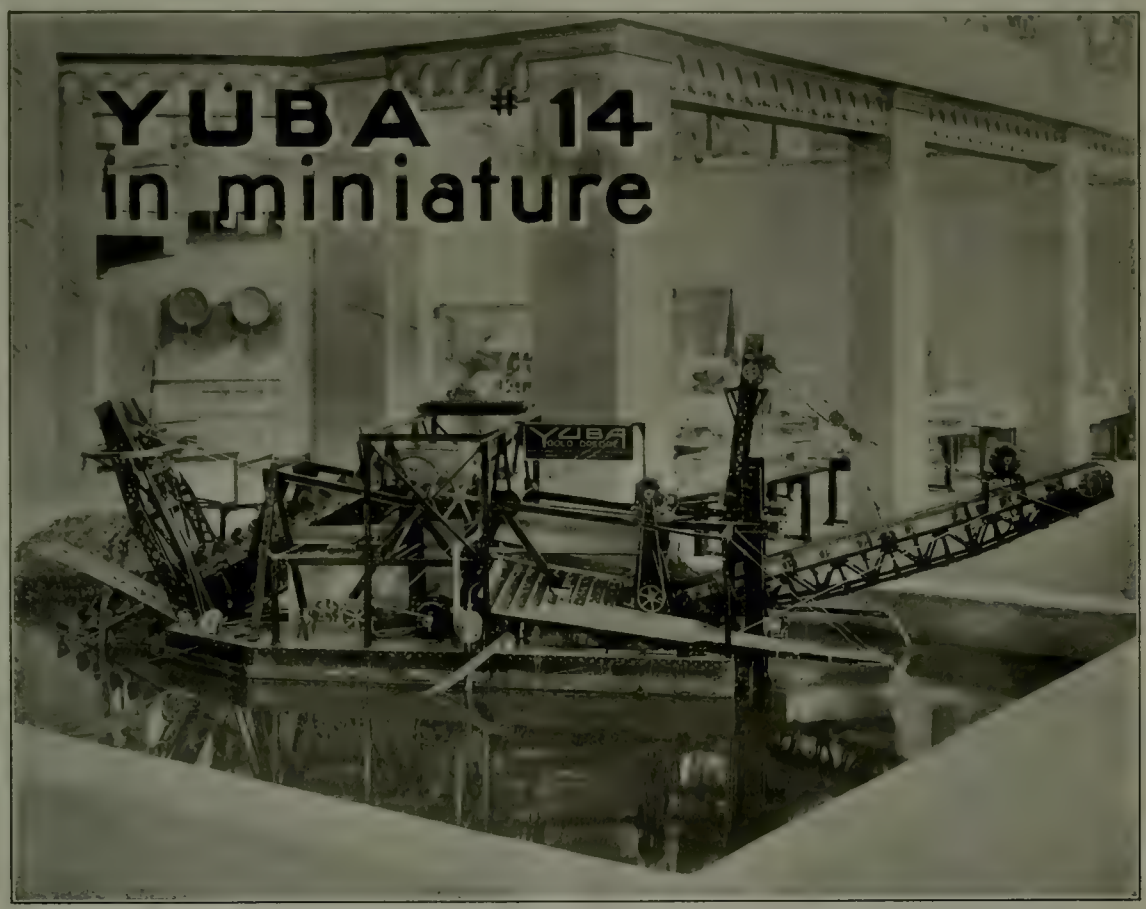
Leather belting is well exhibited at the Panama-Pacific Exposition by the CHARLES A. SCHIEREN Co., of 37 Ferry street, New York. This firm has a number of vertical, horizontal, and quarter-turn drives, the power being transmitted through shafting, friction-clutches, tight and loose pulleys, countershafts, and Lenix drives from a single electric motor to a variety of machines. The head of this concern, C. A. Schieren, died in April.

In the *Press* of April 17 appeared an illustrated description of the large NORDBERG hoist installed at the Inspiration mine, Arizona. One photograph showed the hoist-house, another a side view of the twin hoists, but the drawing consisting of three different views should not have been used in connection with this hoist, a mistake having been made. However, the description and other pictures are correct and illustrate this new system of hoisting.

Mining and Scientific Press

Edited by T. A. RICKARD

Volume 110 SAN FRANCISCO, MAY 22, 1915 Number 21



TWO working models—complete in every detail—of Yuba No. 14 are at the Exposition, one in the Palace of Mines and one in the California Building. Every mining man will be interested in them. A booklet describing these models will be sent on request.

Yuba No. 14, operated on the Yuba River by the Yuba Consolidated Gold Fields, has buckets of 16 cu. ft. capacity and digs 70 ft. below water. It is of steel throughout, and, everything considered, is the largest and most powerful dredge in the world.

The Yuba Construction Company is prepared to design and build dredges, with either steel or wooden hulls, with buckets of from 1¼ to 16 cu. ft. capacity. Our experience is at your service.

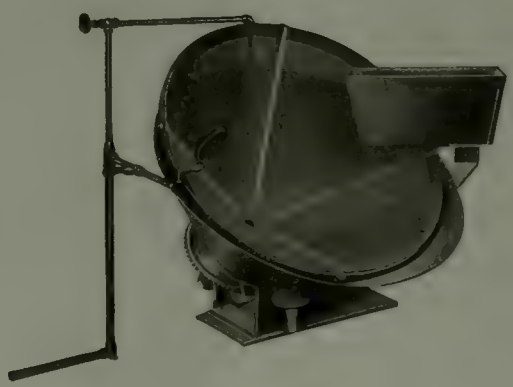
THE YUBA CONSTRUCTION COMPANY

Works:
Marysville, California

YUBA GOLD DREDGES
YUBA BALL TREAD TRACTORS
YUBA HYDRAULIC DREDGES

Sales Office: 433 California St.
San Francisco

BUNKER HILL SCREENS



THE LARGE CAPACITY of the Bunker Hill Screen, its wonderful simplicity, the small mill head and floor space required, and its light weight, are all properties which make possible its adaptation anywhere in a mill. The rapidly increasing demand for this machine is the best indication of its usefulness in ore dressing.

Notes 783
Carbon and cyanidation 784
More research is needed.
The Mining Game 784
The Editor comments on the views of operators as to the relation of speculators to legitimate mining.
Copper and Aluminum 786
Aluminum has become a competitor of copper in industry; their relative advantages are reviewed.

DISCUSSION

FINANCING MINING OPERATIONS.
By Charles L. Paige 787
One who does mining with drill and shovel demurs to our views upon the speculative side of mining and the function of the engineer in appraising mines.
THE OUTLOOK FOR ENGINEERS.
By T. H. Oxnam, Jr. 789
A metallurgist of experience contributes thoughtful observations on this topic.
JAPAN AND CHINA.
By W. S. Kent 789
Commendation of our editorial views, tempered by a disagreement on a minor point.

ARTICLES

THE EFFICIENCY OF TAMPING.
By Edgar A. Collins 790
Excessive use of explosives may be justified in tunnel-driving, where speed of advance is the first consideration, but is incompatible with economical mining. Investigation at an Arizona mine demonstrates that careful tamping permits a saving of 25% in the consumption of explosives without interfering with the speed of work.
PRECIPITATING ACTION OF CARBON IN CYANIDE SOLUTIONS.
By W. R. Feldtmann 791
Carbon is found in many rocks and some ores, its presence has produced difficulties in the recovery of gold by cyanidation. Careful experiment on West African ore containing graphitic carbon has shown that the gold is precipitated by the carbon as a compound, and that alkaline sulphide solution will re-dissolve this. Experiments are in progress to devise a process based on this discovery.
GOLDFIELD RE-VISITED—I.
By T. A. Rickard 797
Goldfield has suffered a decline from its early prosperity, but prospects are again improving. Unfortunately progress is threatened by litigation which eventually may involve nearly all the companies because of conflicting extra-lateral rights. The Editor explains the situation thus created in the first of a series of articles on this interesting district.
THE SAPPHIRE MINES OF YOGO, MONTANA.
By O. W. Freeman 800
The only place where sapphire is mined from the rock in which it occurs is in southwestern Fergus county, Montana. The sapphire found here is of the deep-blue color which is most prized, and over $200,000 worth of the rough stones is produced yearly. After being cut their value is many times increased.
COSTS AT THE SOUTH KALGURLI 802
LEAD AND ZINC SMELTING IN AUSTRALIA 802
The Port Pirie lead-smelting works has been taken over by a company which is jointly controlled by the principal mining companies.
COPPER EXPORTS FROM JAPAN 802
The War caused a decline of 50% in the copper exports of Japan in the second half of 1914.
COSTS AT THE COMMONWEALTH MINE 803
OIL REFINERIES AT KUROKAWA, AKITA-KEN 803
One company is building a plant of Russian design and another a plant of the American type; comparative results are awaited with interest.
EXPERIMENTS ON COPPER ORES BY THE PHELPS-DODGE GROUP OF COMPANIES 803
Research is in progress to determine the best process for treating low-grade ore recently developed in the Copper Queen. Flotation has been found to add 12% to the recovery by ore-dressing methods. At Moctezuma flotation gives less encouraging results.
COSTS AT THE PORCUPINE-CROWN MINE, ONTARIO 804
ALTERNATING CURRENT IN ELECTROLYSIS 804
An alternating current superimposed on a direct current diminishes the back electromotive force of polarization and increases the current strength, if the cell is irreversible.

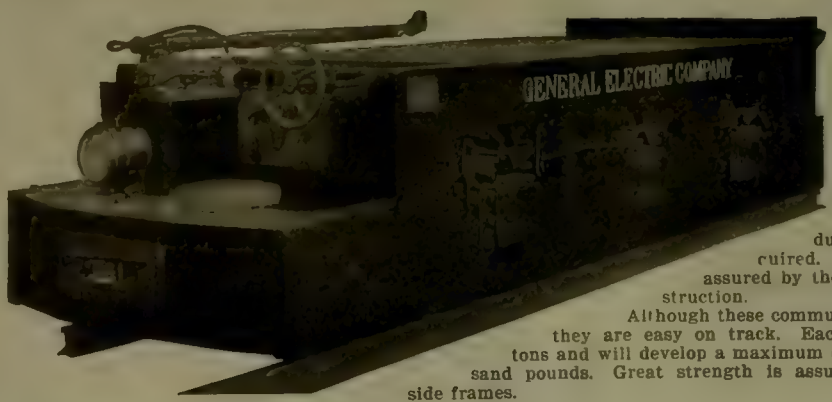
Price, 10 cents per copy. Annual subscription: United States and Mexico, $3; Canada, $4; other countries in postal union, 21s. or $5 per annum.



Built for underground haulage at Rochester and Pittsburg Mining Company and equipped with three motors. Each of these 85 H.P. capacity motors is provided with ball bearings which prevent armature from touching pole pieces, keep oil out of motor, maintain commutator in alignment, cut down bearing friction and reduce quantity of lubricant required. Sparkless commutation is assured by the use of a special motor construction.

Although these commutators have a long wheel base they are easy on track. Each locomotive weighs twenty tons and will develop a maximum draw bar pull of twelve thousand pounds. Great strength is assured by massive rolled steel side frames.

Electric Mining Locomotives
Types For Every Service

Many types of mining locomotives are manufactured by the General Electric Company. For any given set of haulage conditions just the right type of locomotive can be selected. The wide choice possible makes compromises unnecessary.

Two representative types of these locomotives are illustrated to show the wide variety available.

Our engineers will be glad to design or select suitable equipment for any haulage service.

The locomotive shown below will operate from either a 250-volt trolley or its self-contained Edison Storage Battery, but any storage battery can be used in this locomotive.

This locomotive weighs six tons, is for 42" in. track gauge, and will develop a maximum draw-bar pull of 3500 pounds When desired it can be built for a minimum track gauge of 30".

The change from trolley to storage battery operation is entirely automatic being accomlished by an automatic switch which makes the necessary connections. This locomotive's storage battery is automatically charged when locomotive is running from trolley wire.

EDITORIAL

T. A. RICKARD - - - - Editor THOMAS T. READ - Associate Editor

THE useful article on the 'Assay of Cyanide Solutions' in our last issue was written by Mr. O. E. (not C. E.) Roodhouse. Signatures are not always easy to decipher.

BUSINESS continues to expand. The Government forecast of crops is excellent. The volume of domestic transactions is increasing. Idle railroad-cars are less numerous. If the Stock Exchanges have abated their impetuosity, that also is desirable; if the cart precedes the horse, a tangle ensues.

OUR metal-market report from New York indicates the continued strength of copper. Absorption of output keeps pace with the resumption of productive activity. The belligerent nations require copper regardless of cost; there is also a broadening domestic demand for industrial purposes. With peace there should be an immediate need of copper and other metals, for the work of reconstruction.

A JAPANESE recently in Mexico writes to *The Japan Times* to explain that the disturbances in Mexico are a good thing for the native population; the fighting is not serious and casualties are insignificant, he says. If the Mexicans serve as soldiers they earn "1.50 *yen* to 2.50 per day, while they cannot get more than half that amount if engaged in peaceful labor." This Japanese observer concludes that "war is a blessing to them." The point of view is new, and unwelcome.

ZINC continues to advance. It is stated that the Butte & Superior mine has sold 2,500,000 pounds of spelter at 13 cents, delivery to be made at the rate of 500,000 pounds per month for 5 months. The American Zinc, Lead & Smelting Company has sold 3,500,000 pounds on forward delivery, the prices being astonishing, namely, 900,000 pounds ordinary brass spelter at 16¼ cents, 2,100,000 pounds intermediate spelter at 19 cents, and 500,000 pounds of highest grade at 20 cents per pound.

USE of coke is being encouraged in Germany in order that the output of desirable by-products may be increased. Benzol is needed for use in automobiles, sulphate of ammonia is equally essential in fertilizer manufacture, in order to maintain the domestic food-supply. Government buildings and railways have therefore been instructed to use coke as fuel, mixing it with coal when necessary, experience having shown that in firing locomotives, for example, a mixture of one-third coke and two-thirds coal gives satisfactory results.

PRACTICAL details of mining do not lend themselves to lengthy description, as a rule; hence they escape the printed record. Yet they are among the items of knowledge most required and they furnish just the information we are most anxious to give to our readers. Therefore we are particularly grateful to Mr. Edgar A. Collins for his interesting note on the use of 'tamping' at the Commonwealth mine, in Arizona. The experiment made under his direction is also a deserved compliment to the Bureau of Mines, for the test was prompted by a suggestion emanating from that useful department.

TONOPAH is to be congratulated on the consolidation, announced on May 15, of the Tonopah Extension, Tonopah Merger, and Tonopah Victor mining companies. As is generally known, the controlling factor in the Tonopah Extension is Mr. Charles M. Schwab, recently identified with the success of the Bethlehem Steel Company, but formerly president of the United States Steel Corporation—a man of enormous initiative and energy. Under the terms arranged, the Extension will purchase all the Merger and Victor ground, and assume the debts of both the subordinate companies. The Merger will receive one share of Extension stock for every 7 of its stock issued; similarly the Victor will receive one share of Extension for every 8½ shares of its stock issued. The agreement is to be ratified by the several companies at general meetings to be held at an early date. This consolidation obviates the danger of internecine litigation based on supposed apex-rights. While this is the prime motive, we understand, it is also apparent that the unification of property will diminish overhead expenses and give the two minor companies the benefit of.

the excellent technical administration of the Extension staff. In every way the event is of good promise to Tonopah.

IN a sensible little article in the latest bulletin of the Canadian Mining Institute, Mr. Norman R. Fisher discusses the check in the growth of the mining industry of Ontario. He concludes that the explanation is to be found largely in the granting of titles to claims without the obligation to work them. Thus large tracts of promising ground near existing mining centres are closed to the prospector and to others willing to take the chances of exploratory work. We agree with Mr. Fisher that this factor is becoming increasingly operative both in the United States and Canada. No unearned increment is so objectionable as that accruing to the man who alienates a portion of the public domain in order to hold it unproductive while his neighbors develop the ground in its vicinity. Mining regulations should be such as to give the maximum reward to the developer, while taxing the dog in the manger to the point of ejection.

RECENTLY we commented on the Calumet & Hecla's relations with its employees and contradicted the ignorant slander of a local contemporary. Now comes the announcement that the company has set aside $500,000 to be distributed on June 12 among its employees, on the basis of time actually worked. The bonus is to compensate for the wages forfeited by the men, and officers of the staff, through the reduction that was made, in consequence of the effect of the War on the price of copper, on September 1, 1914, and continued until May 1, 1915. Thus not only has the company restored its former wage-scale, but it has re-imbursed its workers for the reduction necessitated during a time of stress. This act came as an agreeable surprise not only to the beneficiaries themselves, but to the entire mining community of the Keweenaw peninsula. It affects 10,000 men, and follows a 10% increase in wages. Yet in the current issue of the paper published by the Western Federation of Miners we read about "the copper heel" in Michigan and we note a violent attack by an insurgent Finn on the company's management, only equalled in ignorance by the San Francisco paper that discussed the same subject. Indeed, the Calumet & Hecla, from the days of Agassiz to those associated with the resident manager, Mr. James MacNaughton, has been identified with square dealing and humane methods. We record the latest evidence of the fact with keen pleasure. Concurrently it is proper to refer to the restoration of maximum wages at Butte, where the sliding scale, based on copper prices, has brought day's pay to the $4 level once again. From the Southwest similar increase of pay is announced; in one case a company had to put another story on the structure of its sliding scale in anticipation of copper rising to 25 cents. Idle men from other districts are flocking to the copper and zinc mines. 'Tis a poor sort of prosperity that does not benefit employer and employee alike. We rejoice in the growing sense of fairness characterizing the administration of mining affairs.

Carbon and Cyanidation

We publish a valuable article by Mr. W. R. Feldtmann on the precipitating action of carbon in contact with cyanide solutions containing gold. This was presented as a paper before the Institution of Mining and Metallurgy, in London, and as not many of our readers see the bulletins of that technical society, we are glad to reprint the article in full. Both the reputation of the author and the interest of the subject warrant the space we give. To those engaged in mining on the Mother Lode, in California, the experiments made by Mr. Feldtmann will be of immediate value, because the precipitating action of carbon has been as much a metallurgical nuisance to them as to the technical men in West Africa, black shale encasing the veins of gold-bearing quartz in both regions. It is generally recognized now that it is not graphite but other forms of carbon that do the mischief. Graphite is a form of carbon that has been completely altered by heat and pressure; it is too dense to act as a precipitating medium. The action is due to occluded gases of the hydro-carbon type emanating from organic matter while in process of coal formation. The gold is precipitated by adsorption through the agency of these occluded gases. This constitutes one of the main hindrances to cyanidation on the Mother Lode, for it diminishes extraction while also increasing the consumption of cyanide. The former can be mitigated by the use, as shown by Mr. Feldtmann, of sodium sulphide, which is a solvent for the precipitated gold, although the cyanide is not; but the alkaline sulphide does not remedy the high consumption of cyanide. However, the experiments recorded by Mr. Feldtmann point the way to further research.

The Mining Game

If a Cornishman of the old-fashioned kind were to visit Nevada he would find that 'mining' does not signify the same kind of thing at Goldfield and at Camborne. In the heyday of the Cornish tin industry it was the custom for a number of men to start a mining enterprise on the basis of joint liability and assessment, the working capital being called-up as required. This was known as the cost-book system, which has now been discarded for limited liability and the joint-stock company. The operators were called 'adventurers' and they constituted a sort of private syndicate for the exploitation of a mine. In the early days of the Comstock, a subdivision of interest was effected by dividing the property into shares equal in number to the feet measuring the length along the lode. Dealings took place in 'feet,' not shares. Later it became convenient to sub-divide the holdings still further, so the 'share' idea was developed, until the ownership was spread among a million or more units. That facilitated gambling, by decreasing the value of the counters in the game until policemen and servant-girls could participate freely. Thus the 'mining game' was evolved. At first crude and clumsy, it has

been developed into complicated activities involving the exchanges and the press in a business of far-reaching magnitude. Of course, the whole system is alien to the ideas of the mining profession or of the real exploiters of mineral deposits, not of other people's pockets. It is a condition and not a theory; as such it should be recognized and studied. During a recent visit to Nevada we discussed the question with sundry persons engaged in the business, from tipsters on the train to managers of big mines. For instance, an intelligent young man complained that the management of the Nevada Wonder mine was "too conservative"; the Philadelphia controllers of this successful property "never let anything out"; there was "nothing doing in the speculative way." To our informant it seemed desirable "to create interest." Another company, the Tonopah, "did the right thing," so he said, because "they gave out a good deal about the mine." Finally, he sat back and concluded with the assertion: "What is wanted is publicity." On cross-examination we ascertained that he felt aggrieved because his Nevada Wonder shares ranged in quotation from $1.75 to $2.50 only. That afforded a dull market. He had no reason to believe that good news concerning the mine was withheld by the management or that any attempt at a 'freeze out' was being made. No, he simply objected to the lack of "speculative interest" in the stock. In short, he thought himself entitled to expect that the management would publish information calculated to excite active dealings, resulting in a wild inflation of the quotations. That was his kick. He had not bought a participation in an industrial enterprise; he had bought a counter in a game; and the game was too slow to suit him. He liked the sort of publicity that makes a market for low-priced shares among the gullible public. That brought up the mention of George Graham Rice, *alias* Herzig, *alias* Shefftels, who, under various guise, developed 'the game' to the point where the Government found it necessary to afford him the restricted hospitality of one of its official residences. He is the great protagonist of the mining 'game' and of those press activities that beguile the public by means of piffle plentifully printed. At Goldfield his paper, *The Mining Age*, circulates freely; in the hotel a notice-board gives it special prominence. We shall be absolved of journalistic jealousy if we mention these facts as a pitiful commentary on this phase of mining in Nevada. A basic industry is prostituted. The fact is recognized by reputable citizens, who yet will assert that the scribes and parasites create "speculative possibilities" and "bring money to the mining camps." As one of them said: "I've got a claim near a rich mine, but you can't sell a proximity to a capitalist represented by an engineer." The inference being that you can capitalize a 'proximity' by peddling shares to the public. And you can. It is done daily with great success. From a few cents the shares of a puling wild-cat can be hoisted to dollars on the strength of the flapdoodle published in utterly irresponsible publications. Indeed, it is claimed that mining operators of some repute will use Rice to boost their stocks, employing him as a tool for unloading the scrip of unhappy enterprises. One of these gentlemen told us that "you can't raise capital for legitimate mining, leastways not so as to make any money." Further he claimed that publicity *à la* Rice was not needed for legitimate business, but it was essential to "the stock game." We quote these views in no frivolous spirit. They represent a current notion that must be examined carefully by those having the true interest of mining at heart.

How does it work? In the first place, the mining communities of southern Nevada are nearly bankrupt because the residents have been beaten at their own game. Men that know the trickiness of the share-peddler and are aware of the facts concerning a particular hole in the ground will buy shares when a publicity campaign is started, expecting to climb upon the band-wagon before it upsets, but often, by reason of their own greed or an unexpected turn of a trick, they are caught. It is not easy to forecast which way a wild-cat will jump. Of the multitude of simpletons that buy 10-cent shares on the strength of disreputable tricksters, we have nothing to say. It is doubtful whether even a paternal Government can keep them from parting with their savings. But of the miners that participate we must say something. Theirs is a pathetic part to play in this farce. The men employed on the mines have caught the fever of speculation and deal in shares. Some of them are employed to act as informers or "do gum-shoe work" for brokers, who 'carry' them on their books for a block of shares. The real miner is a poor hand at the game because he is a bad seller; once he buys he becomes "married to his stock." One miner in the Jumbo Extension is said to have made $10,000, but such gains are like a lottery winning: one hears much of it, and very little about the thousands that drop their savings into the maw of deceitfulness. Few miners have any idea of the proportion existing between a 'strike' of rich ore and the intrinsic value of shares in an over-capitalized company; as soon as a discovery was made in the Jumbo Extension, for example, the share-valuation of the mine doubled, at once, before time had been given for any systematic development to prove the extent of the ore-body. From the miners the share-dealing extends to some superintendents, which is even more dangerous, because it tends to vitiate reliable sources of official information. One superintendent—and a capable one too—formerly in Nevada wrote recently from Arizona to ask for an appointment at Tonopah and expressed his willingness to take lower pay because there was "no chance to play stock in Arizona." He thought there was more money to be made in the game of spoof and chicane than in digging ore out of the ground. We believe this to be not only poor morality but a pathetic illusion. Most of those that play 'the game' are beaten by their confederates, known or unknown. All of them try to "catch a sucker" bigger than themselves and most of them fail to find him. It is a miserable interplay of greed and knavery, and bears but little relation to genuine indus-

try. What the tout is to the race-track the tipster is to the share-market; and the race-track is related to horse-breeding as the share-market to the industry of mining. We shall discuss other phases of the subject in later issues of this periodical.

Copper and Aluminum

During October of 1914, electrolytic copper sold for an average of 11.1 cents per pound; the average price for April of this year was 16.64 cents and the average quotation for last week was 18.75 cents. This week will undoubtedly show a continued rise. On the face of these facts the copper producers might be expected to exhibit great jubilation, and the absence of such a demonstration is due to the general recognition that this phenomenal rise is caused by abnormal conditions created by the War, which first served to depress the price of copper and later to raise it. Copper is used, in a variety of ways, in making munitions of war. Ammunition is now being manufactured for the belligerent countries, not by the millions of dollars worth, but by hundreds of millions, and an excessive demand for copper has thereby been created. The producers are not neglecting to make hay while the sun shines, but they are not blinded to the fact that so favorable a condition cannot be expected to persist indefinitely. No one can know when the War will come to an end, still less to foresee whether the conclusion of peace will merely cut off the war demand without restoring normal consumption, or will give rise to increased industrial consumption in repairing the ravages of war. The most probable effect will be a sharp slump in demand on the conclusion of the War, followed by a gradual increase, stimulated by reconstruction in the regions laid waste by the War.

Meanwhile a number of other considerations have to be taken into account. We have already referred to the possibility that the Germans, having been forced by military necessity to diminish their ordinary consumption of copper, may so successfully overcome the difficulty that they will not only be able to get along permanently with a less supply but will teach the rest of the world to do the same. The copper industry of the world has been developing on the basis that the rapid growth of consumption, which has averaged 9% per annum for the past 15 years, will continue. If this proves not to be the case an over-supply of copper and correspondingly low prices for the metal seem likely to characterize the period immediately following the War. Some hint of the progress being made in devising substitutes for copper can be gleaned from the reports from Germany that a special soft iron is being used instead of copper for the manufacture of ammunition. But the most serious competitor of copper is aluminum. A little over one-half of the world's production of copper is used in the electrical industry. As pointed out in the editorial review of aluminum appearing in our issue of January 3, 1914, the two metals are on a par from the standpoint of cost when aluminum sells for 20 cents per pound and copper for 13 cents. The quotation for aluminum week before last, for prompt delivery, was 19.25 cents per pound. The competition from aluminum has not been serious as yet, especially in this country, since the output has been small, being confined to one company. As pointed out in the editorial mentioned, this situation has entirely changed, for the production has greatly increased and a rival company plans to enter the field, so that aluminum is likely to sell at lower prices than have ruled during recent years. The copper industry heretofore has been on the basis of being able to concentrate its attention to the making of a metal that the world had to obtain: now it must adjust itself to the finding of a market for its product. In other words, the copper industry has been in the position of a manufacturer whose goods sold themselves; now it bids fair to be in the position of a manufacturer who must devote a large part of the energy of his organization to the selling of his goods.

In general industry the competition of aluminum with copper seems to be more serious even than in the electrical. There are some fields in which it seems improbable that copper can be displaced; in others it certainly can be. Aluminum has been handicapped in this country by the business policy of the principal company, which not only produced the metal, but also manufactured it into finished products. Probably this was necessary in order to convince manufacturers that aluminum could be thus used, but it also served to deter manufacturers from embarking in the business, since it is obvious that a manufacturing company controlling the price of the raw material can, as soon as it feels competition from other manufacturers, put them out of business by raising the price of the raw material. The company would certainly make money, either on the raw material or the manufactured product; the rival manufacturers would have no chance at all to make money. If manufacturers can buy aluminum in a competitive market they have more chance to make money through efficient methods of fabrication and marketing, and the use of aluminum has a corresponding opportunity to expand. Another serious feature of the position is that in most miscellanous industries the size, rather than the weight, of the object is the controlling factor. Because of its light weight, 100 pounds of aluminum is thus able to displace 250 or 300 pounds of copper or brass. Any gains made by aluminum in competition with copper are thus seen to be attended by a much greater loss by the latter metal. The rôle of a pessimist is an unpleasant one, and we trust that accusation may not be laid at our door. What we hope is that the copper industry will not fail to read the signs of the times, and prepare to meet the probable developments of trade. Next to the iron and steel industry, copper is the most important of the metallic mineral products of this country. It is so intertwined with the general prosperity of the nation that not the producer alone, but the whole nation, is concerned in its prosperity. We hope that, through foresight and ingenuity, this prosperity may not be endangered. Copper at over 20 cents is abnormal and unhealthy.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Financing Mining Operations

The Editor:

Sir—Mark Twain, in his book 'Roughing It' tells about a mining associate of his named Ballou. Mr. Ballou was an old miner, a geologist, and a chemist, for he had some knowledge of rocks, and he managed to brew coffee with alkali water in the desert. The party found the coffee a failure; even Ballou, after drinking a portion of it, was forced to announce that it was too technical for him.

The appositeness of this story is perhaps vague, but it has often recurred to me when I have tried to glean the wisdom offered by technical or professional writers and speakers. If we laymen turn to theology we find a language in which spiritual allusions and similes leave us depressed and humiliated; if we try a law-book we are bewildered by strange phrases: if we take up a medical work, and do not lay it down quickly, we become the prey of some doctor who will treat us for brain-fever, and all because of the razzle-dazzle of the barbarous lingo. And so it goes through scientific literature, which is presumed to embalm knowledge for general distribution, but buries it like a bug under a brickbat.

I have sometimes wanted to contribute to your journal my opinions or experience on subjects discussed, but usually there is a halo of professional sublimity over them, or a maze of arbitrary or technical terms too profound and dangerous for me. Some writers seem to have copyrighted all admissable knowledge upon their subjects, and they file it in condensed formulae. They fight, or write, by the book of arithmetic, one, two—and the third is in your esophagus.

Of course the *Mining and Scientific Press* is broad-gauge and admits articles in the ordinary vernacular, but over many of the topics hovers some professor with his hammer, ready to flatten us like a lead button and then cupel us to nothing. We admit that professors are protected by law and are admitted socially, in some circles; and that some of them have a following. Some of them are mellow; some of the older practitioners are not so gay with scarfs and bannerets as the lighter vessels, emerging later along. You may now and then also meet technical graduates, even from colleges, who speak wisely without flourish and who write rationally, perhaps instructively, outside the rules of arbitrary technology—or whatever it is that they practise. Generally it is the new young technician whose college accent bewilders us.

With the foregoing apology for my diffidence, together with the explanation that I am not a speculative miner but delve with pick, shovel, drills, and dynamite, your readers will know that I do not live chiefly to fill the world with words. But when such a topic as 'Financing Mining Operations,' introduced by Robert H. Todd in the issue of April 17, and somewhat modified by the Editor in his article 'Speculation in Mines,' arises, almost any of us can get busy. In fact, some of us can delve 'one yard below your mines and blow them at the moon.' The last sentence shows that Shakespeare was no slouch in mining matters.

Mr. Todd makes some true statements and draws sensible conclusions as to what may be termed the financial indisposition that retards digestion in mining particularly gold mining—most notably in California, specifically northern California, and especially in this immediate region—in fact, in my own vicinity.

The Editor's concentration of the topic into two basic ideas (1) that mining is essentially speculative, and (2) that the only appraiser of a mine worthy of confidence is the properly qualified engineer, contains too much sand and slime to assay very high by ordinary blowpipe analysis. My gorge arises when it is thus asserted, as a basic idea, that mining is speculative! This by an apostle of the 'precision of thought' doctrine so lately advanced in these columns! Any old dictionary defines speculation (in its commercial sense and application) to mean buying and selling, that is to say, dickering in a commodity; but I cannot find that mining is speculative, speculation, or that it is done by dickering. It is clear to nearly all of us, in our calm moments, that speculation has done more to prevent mining than anything you could mention. The Editor's view of mining is deflected. Did speculation develop the Comstock, or did the Comstock develop speculation? Did speculation discover or develop Cripple Creek? Did it Guggenheim Alaska? Permit me to assert, as affably as I can, that mining is an exact science, if there is such a thing. Mining is digging. If we do not dig we do not mine, though we speculate until doomsday. Speculators are a kind of parasite—barnacles or snails—not miners. Mining may be hazardous, like other ventures, in fact, all excepting death and taxation, the only sure things. Speculators risk nothing; they only buy paper, or something else, and get it; if they can or cannot sell it they are not affected by mining operations, but operations may be sadly affected by speculators.

The small speculator is more valuable to industry and progress than the 3 or 4% capitalist, who is more conservative; but it is most pitiful to separate the former from

his money, which is often borrowed money, and so is gone twice over. The small speculator who is unable to sell his paper is the fellow who fills the magazines with accounts of mine swindles, largely mergerizing his accounts; and all the while mining, to him, is an unknown process. Probably he never looked for, or saw, a mine. But he will condemn mining, just as men a thousand miles from a race-track condemn a horse that loses a 100 to 1 bet for them. All this is mere iteration, stale, flat, and unprofitable, but let it go as cumulative testimony *Stet*.

A higher, at least a more powerful, order of speculative mining is followed by the fellows who buy, annex, or acquire real ores and mines. They or their agents actually visit and examine mines, sometimes at a distance from good hotels and pullman coaches. Their specialty is ore on the dump, but as next best they sometimes stope out and remove it from a well-opened mine. This order of speculative operators is often strong enough to build great reduction works and smelting-plants; primarily, they do not mine. They only annex, acquire, remove, and exploit; incidentally often devastating wide areas of public domain to enrich a small group of far-away capitalists and non-resident share-owners. We do not hear of their grub-staking a prospector or making any effort at outside development, discovery, or conservation.

The Editor's second basic idea, (2) that the only appraiser of a mine worthy of confidence is the properly qualified engineer, is more pepper in my eye. It reads so nicely that it appears as good and safe as cyanide bullion. It should be sound counsel for speculative process of mining. When they have decided upon the properly qualified engineer, conceding his honesty, his judgment, his industry in examination; when they have read and digested a competent report and have perused the proved assays; then they may concede he has made a better guess than they could have done, as to the safety of investing, particularly if the report is unfavorable to the mine. But if they expect the best engineer to be infallible they overtax human nature, if not the profession itself. Engineers, like mines, may sometimes be salted; or, like mines, misleading. The best judgment may be warped by circumstance. The most careful sampler may be misled by his own samples. The assays upon which his report rests may be a little erroneous. Again, the engineer may not know of, or have facilities for, reduction tests of the particular ore examined. Any one of these, and many other details, may be determining factors between profit and loss.

It appears that Mr. Todd's basic idea, too, is the welfare of investors in corporation shares, and he recommends the general assessment of such investments. Most assuredly it is the most essential and equitable process, for it is seldom that a mine, or any business, continues without difficulty or reverses. Why should investors, who associate themselves for the purpose of mining, want to evade paying their share of losses, any more than partners in any other business? It is a singular expectation for people to buy an interest in a business with the proviso or hope to share nothing but profit, a guaranteed dividend all the time. When they expect this they deserve that their selfishness be rebuked. It is as though partners contribute to a mining venture and send one of the members down the shaft to explore; if he finds treasure, they agree to hoist away and divide the product; if he finds nothing, they expect to leave him in the hole and abandon the partnership; and then, if he calls in outsiders and makes a discovery and gets out treasure, the deserters often expect to share what, by business rules and moral equity, they have forfeited. Such faint-hearted financiers are not rare. They should not invest in mining, nor in any other industry. Let those who fear their fate too much, and whose deserts are small, rather invest in sound securities such as town-lots, not assessable. When the town-trustees vote improvements or development they merely condemn and confiscate small investments.

In this region capitalists looking for mines are scarcer than volcanoes, as there is one of the latter in sight part of the time. Here is a region richly mineralized, that has yielded many millions in gold, silver, and copper, and where mining has been done for 66 years. A hundred veins yielding gold outcrop on every square mile of it, but it does not show an average of one shaft 50 ft. deep per square mile, and not more than a dozen mines equipped for even limited exploration. Mining for gold and silver in northern California languishes for lack of men affluent enough to buy a gasoline touring car, and give us 'the once over.' Prospectors and promotors alike have neither credit nor encouragement and are degenerating into 'pocket-hunters' and 'snipers.' Hundreds of them have abandoned claims and locations where they could not get food or equipment to continue or remain.

"Ill fares the land, to hastening ills a prey,
Where wealth is mergerized and men decay."

CHARLES L. PAIGE.

Shasta, California, May 8.

[We are glad to give space to the expression of views unlike, or even opposed to, our own. Mr. Paige's ruminations are decidedly interesting. He and his comrades need not hesitate to contribute their opinions to our columns if they write thoughtfully, as in this case. We stand between them and the 'high-brows.' The academic person does not always understand the practical. We find ourselves in sympathy with both. Both are necessary in the scheme of life. We deprecate a sneering attitude on the part of either. The professor of mining might be a useless person if the man with the drill did not make mines, but the gentleman behind the drill would be lacking in much necessary information if the professor did not collect it and systematize it. Mr. Paige's objection to the use of 'speculative' in connection with mining is interesting to us, as anybody who disagrees with our view is necessarily more interesting to us than one who is of exactly the same mind. We advise Mr. Paige to exchange his "old dictionary" for a new

one. Speculation is the risky use of money or time in the hope of gain. The prospector who swings his pick to earth is a speculator; he is spending his strength and time on the chance of finding more than enough ore to compensate him. It is true the excess of speculation, especially in paper transactions, is injurious to legitimate mining. Insane gambling is an exaggeration of sane speculation. Without speculation mining would cease; without speculation in thought mankind would vegetate. No, Mr. Paige, mining is not "an exact science," it is an art to which science is applied with varying success. We are sorry if our insistence on the idea that the only appraiser of a mine worthy of confidence is the properly qualified engineer should cause our correspondent to sneeze violently. The idea is one to which we cling with great tenacity, and we expect to advocate it with iterative effect. No, we do not claim infallibility even for the best engineer. None of us is infallible, not even the youngest. But efficiency in any work is only possible to those who have had the proper training and experience. We have no more confidence in the boy wonder than in the ancient mariner. Efficiency is the result of scientific teaching and wide experience.—EDITOR.]

The Outlook for Engineers

The Editor:

Sir—The article by 'KCN Engineer' on this subject is indeed an interesting one, especially what is said about the graduates who drop out within four years of graduation, and also married men *versus* single men.

It has impressed me more strongly each succeeding year that perhaps the trouble lies more with the men who take up mining as a profession than with the profession itself. Possibly the foregoing statement should be qualified to specify those who drop out. Is it not true that a large number of the men entering our mining schools know practically nothing of the life and work of the profession, and within two or three years after entering the field drop out because they are in no way suited to it? If such is the case, we then have a surplus of college-trained men looking for positions such as they are supposed to be capable of filling. Owing to competition, which as a result follows this surplus, they take the positions open at lower salaries than would be the case if fewer men were available. If, in place of a collegiate degree now required by some of our technical schools for entrance, one or two years' field-work was required, would not a large proportion of those who fall by the way be eliminated at the start, thus reducing the surplus and bettering conditions for those who do persist?

Another reason, I think, why salaries are low, is the consolidation of a number of properties under one management, thus reducing the number of men needed for technical work; in other words, reducing the overhead. This reducing of overhead expense is without a doubt necessary, but it does reduce the number of positions open to the young engineer.

Is it not true that married men will stay with a job longer than a single one? If so, from an economical standpoint, would it not be cheaper to provide the accommodations for the married man? I have always heard it said, and experience has taught me its truth, that a changing crew or staff is never an efficient one. Like your correspondent, I am an optimist and do not write this because I have reached the point where every other business looks good in comparison to mining.

Los Angeles, May 5. T. H. OXNAM, JR.

Japan and China

The Editor:

Sir—The leaders that you publish from time to time on questions quite irrelevant, for the moment, at any rate, to the title of your magazine must come as refreshing showers after drought to miners and prospectors in remote corners of the world, who have not the opportunities of libraries and reading rooms, and are largely dependent, for their information about such subjects, on the blatant braying of the daily press and on magazine articles—too often purchased by interested parties—the columns of which are intercalated by advertisements.

'Japan and China,' in your recent issue, is such a leader, and while I fully endorse the greater portion of it there is one point about which I am far from being in accord with you. With regard to the marching of Japanese troops through Chinese territory to accomplish the investment of Kiaochou, you say: "As a gross violation of neutrality the action of Japan was on all fours with the invasion of Belgium." Hardly on all fours. While I do not wish for one moment even to appear to condone the Japanese offence, which is greatly to be deplored, I can hardly consider it on a parallel with the German invasion of Belgium, for, it must be remembered, Japan had not guaranteed the neutrality of China, as Germany had of Belgium.

W. S. KENT.

San Francisco, May 10.

THE WASP NO. 2 MILL IN 1914. This mill in South Dakota treated 176,140 tons of $2.302 ore last year, and theoretical and actual recoveries of gold and silver were as follows:

	Gold		Silver	
	Fine oz.	Value.	Fine oz.	Value.
Called for by assay of heads	17,178	$355,073	50,600	$27,248*
Called for by assay of tailing	4,498	92,977	31,217	16,811*
Apparent extraction, difference	12,680	$262,096	19,383	$10,437*
Apparent extraction, per cent	73.81		38.30	
Actual recovery, mill ore	12,402	$256,380	14,533	$ 7,952
Actual recovery, slag	206	4,126	3,057	1,520
Total recovery	12,608	$260,506	17,590	$ 9,472
Actual recovery, per cent	73.31		34.77	

*Calculated at 53.85c. per fine ounce.

The ore that goes to this mill is mined by steam-shovel. A few feet of overburden lies above the deposit. Treatment consists of coarse crushing and cyanidation.

The Efficiency of Tamping

By EDGAR A. COLLINS

Probably most mining engineers and superintendents incline to the belief that by 'stemming' or 'tamping' a hole loaded with explosives, the breaking efficiency of the explosive will be increased. The word 'stemming' is used by the U. S. Bureau of Mines to denote the action of packing clay, or other material, into the mouth of a hole to make it air-tight; while the word 'tamping' is used to denote the material used.

But, while stemming is generally recognized as good practice in mining operations, it is seldom systematically employed in the metal mines of this country. The reason for this is probably due, indirectly, to the almost universal use of machines to break the ore, and to the fact that with their use on a large scale, the breaking effect of individual holes is lost sight of in the general result.

Fifteen or twenty years ago, when hand-work was the general method employed for drilling ground, and holes were drilled with very much more effort and expense than at present, the young miner was taught how to load and stem his holes so as to obtain the maximum effect. With the advent of the machine-drill, however, the entire face of a heading was drilled and blasted simultaneously, so that the failure of one hole to break affected the results of the whole round, and consequently, an excess of powder was frequently used in order to be 'on the safe side.' At the same time stemming became rather the exception, especially with the younger miner, who frequently became a full-fledged machine-man within a few weeks without having had any previous training in the economical use of explosives.

With development work in which speed is the main requisite there is some excuse for using more explosive than necessary. Unfortunately, however, the same tendency naturally follows in the stopes, and it is here that the greatest waste is liable to occur.

The thoughtful mine-manager or superintendent naturally views a decrease in his powder bill with enthusiasm, and, as I have, he may have considered the possible advantages of a more general use of tamping. Until recently, no conclusive data covering reliable tests have been available, and not unnaturally, he may have shrunk from carrying out an elaborate series of tests.

It was under these circumstances that I ran across Technical Paper No. 17, by W. O. Snelling and Clarence Hall, recently published by the U. S. Bureau of Mines on this subject. In it complete data are given showing the increase in explosive force gained by using varying amounts of different material for tamping. These tests showed such a remarkable increase in the explosive efficiency, by using even a small quantity of almost any tamping material, that all doubts were at once dispelled. The pamphlet was given to the mine-foreman and shift-bosses to study, and as a result it was decided to test the theory on a large scale.

At the Commonwealth mine the shrinkage-stope system is employed to win the ore. Holes are drilled with Waugh stopers about 4 ft. deep, and from 3 to 4 ft. apart. The ground is medium hard and makes 'mean drilling,' but it breaks well. The regular charge of explosive heretofore had been three sticks of 1 in. 35% ammonia gelatin. Instructions were given to issue only two sticks of powder per hole, and to give each man a large ball of clay. The men were notified that six inches or so of the clay was to be tamped in each hole on top of the powder, and that if this was done the holes would break as before. They were particularly warned not to drill the holes closer together, and were informed that they would not be blamed in case the holes did not break, provided that they could show that tamping had been used as per instructions. At the same time they were given to understand that the failure to break would be considered as evidence that tamping has not been used.

The result of a three months' test in the stopes has justified our faith, and has shown an apparent saving in the consumption of explosives amounting to almost 25%. The word 'apparent' is used advisedly, as with our system of mining, it is impossible to state the exact quantity of ore broken in any month, and the only guide is the amount of powder used per hole drilled. The following figures show the comparative consumption of powder for the last three months, during which the test has been in operation, and for the preceeding three months.

	Average number of machines.	Holes per machine.	Total holes.	Total powder, lb	Powder per hole, lb.
January-March	23.1	10.8	21,385	21,323	0.997
Previous 3 months	19.5	8.5	15,126	19,915	1.316

In explanation of the much greater number of holes drilled during the last three months, it should be stated that more time was spent in drilling, and less in 'barring down.' This was due to the stopes being narrower.

There is, of course, the possibility that in some cases holes have been drilled closer together, since the change was made. This point has received careful attention, however, and it is believed that there is no appreciable offset from this cause. In the opinion of the foreman and shift-bosses, the holes are being drilled practically as before, and the saving in explosives therefore is a real one. Following up these results, instructions have been given to cut down the amount of powder issued to the development points from 10 to 20%, and the experiment will be carefully watched.

The full benefit of 'stemming' will only be obtained if systematically enforced throughout a mine. It is necessary to provide plenty of suitable material at some convenient point, so that there is no excuse for not using it. This, however, is not all; intelligent and interested supervision is necessary to insure its general use, and to overcome the passive resistance that many men offer to all innovations. At the Commonwealth, the clay is obtained from the more slimy portions of the tailing-dam, after it is partly dried by the sun. It takes a man about half a shift to gather enough mud for the day's supply, and to work it into a stiff clay. It is then sent underground, to the various magazines, and is issued with the explosives.

Precipitating Action of Carbon in Cyanide Solutions

By W. R. FELDTMANN

*The question of how charcoal and, in some cases, graphitic carbon precipitate gold from cyanide solutions is an interesting problem which has only recently begun to attract attention. There is a considerable amount of literature on the subject of the precipitation on charcoal of gold from gold chloride solution,[1] and much has also been written on absorption and adsorption by charcoal[2] of gases, salts, etc. A number of letters and articles have appeared in the technical press dealing with 're-precipitation' of gold from cyanide solutions, but these, as a rule, have merely been in the nature of a relation of difficulties in extraction due, or assumed to be due, to presence of carbon in the ore treated. In October 1913 a paper was read before the Institution of Mining and Metallurgy[3] in which the first serious attempt was made to trace the rationale of the precipitating action of charcoal in auriferous cyanide solutions.

The present writer, who has had occasion to investigate rather closely the precipitating action of some 'graphitic' ores, and has incidentally collated some data on charcoal precipitation, will endeavor in the following paper to present such of the results obtained as appear to be relevant to a better understanding of a perplexing subject.

The quartz veins being worked by several of the West African gold mining companies are intimately associated with a carbonaceous schist. This schist, graphitic in appearance and frequently referred to locally as 'graphite,' causes considerable trouble in the cyanide treatment of tailings and slimes. It has been assumed, and rightly assumed, that poor extractions are, in part at least, due to gold dissolved from the ore becoming 're-precipitated' on the carbonaceous schist mixed with it. But it should be understood that the term 're-precipitation' does not imply anything in the nature of a reversed action of the solution at any stage of treatment, but merely that a process of precipitation accompanies, and is contemporaneous with, the dissolving of the gold from the ore—the final effect being to transfer part of the gold from one constituent of the ore to another—from the quartz to the schist. The trouble, it is true, can be and has been evaded by cutting out wet crushing, amalgamation, concentration, etc., and substituting dry crushing, roasting, and cyanidation of the whole of the ore as one product. The dry-crushing and roasting treatment gives satisfactory extractions and presents other convenient features, but it is, naturally, a costly process, suitable only for the richer ores.

That the graphitic or carbonaceous schist of the West African mines precipitates gold from cyanide solutions has been determined by numerous experiments. The maximum amount that the schist will precipitate is roughly proportional to the percentage of carbon in the schist, and the finishing or load point is fairly sharply defined. In general, where a maximum load-point was aimed at, it amounted to from 4 to 7 oz. of gold per ton of schist. That the cessation of precipitation represents a 'load-point' of the schist, and not a change in the action of the solution due to contact with the schist, is shown by the following experiment:

Five beds of the schist, previously crushed to —10 and +30-mesh and each weighing 300 gm., were placed on filters. Five cyanide solutions each 1200 c.c. and all carrying 0.13% KCN and 36.9 dwt. gold per ton were passed through these beds as follows:

No. 1	solution	through	beds	1	to	5	in	series	in	30	hours.
No. 2	"	"	"	1	"	4	"	"	"	24	"
No. 3	"	"	"	1	"	3	"	"	"	18	"
No. 4	"	"	"	1	and	2	"	"	"	12	"
No. 5	"	"	bed	1	in			"	"	6	"

A portion of each solution was then assayed with the following results:

No. 1	solution	after	passing	5	beds	in	30	hours	assayed	Trace.
No. 2	"	"	"	4	"		24	"	"	0.33 dwt.
No. 3	"	"	"	3	"		18	"	"	19.80 "
No. 4	"	"	"	2	"		12	"	"	35.50 "
No. 5	"	"	"	1	"		6	"	"	37.70 "

From the foregoing example it is clear that the precipitation is limited only by the amount of the precipitating agent contained in the schist on which the auriferous cyanide solution is allowed to act. No. 1 solution, after passing through 5 beds of fresh 'graphite,' is completely precipitated. No. 2, after passing through only 4 beds, already partly charged with gold, is also precitated fairly completely. Solution No. 4, passing through two beds of nearly fully charged 'graphite' was hardly precipitated at all. Before No. 5 solution was applied to No. 1 bed the latter was completely charged and no more was precipitated. That No. 5 solution came off actually slightly higher in gold than it went on to No. 1 bed is probably due to the fact that the gold precipitated does not remain absolutely, although nearly, insoluble in cyanide solution. The full load for the sample of graphitic schist used in the above experiment appears, from the solution-assays, to be about 7½ oz. per ton. The actual assay of No. 1 bed, after water-washing, was 7 oz. per ton.

Obviously, as long as any of this graphitic schist is mixed with the ore, it is bound to be an important factor

*A paper read before the Institution of Mining & Metallurgy, London, on April 15, 1915.

in—if, indeed, it does not constitute the root of—extraction difficulties. To some extent the cyanide treatment is bound to bring about a transfer of the gold contained in the quartz or ore proper, in a form in which it is soluble in cyanide, to a state of gold precipitated on the 'graphite,' in which condition it is nearly insoluble in cyanide solution. Unfortunately a considerable admixture of the schist with the ore is inevitable, as it not only occurs as a friable selvage on the walls but is actually sandwiched in streaks through the veins, especially where these are richest.

At first it seemed to me that to assume, without further investigation, that the precipitation was due to the action of carbonaceous matter in the same sense that charcoal acts, would be merely to substitute one mystery for another. Moreover, it appeared that in the case of the somewhat complex 'graphitic' schist quite other causes might be at work, whether in the shape of some relatively uncommon element or of some unusual combination of common elements. I set myself, therefore, in the first instance, to endeavor to find out what the actual precipitant might be—which is clearly present in limited quantity only—or, alternatively, to eliminate it by way of pre-treatment or to satisfy it by 'loading' it with some metal or substance other than gold.

A typical analysis of the 'graphitic' schist is as follows:

Silica	45.75 (in part quartz)
Alumina	22.57
Ferrous oxide	7.98
Manganous oxide	0.28
Lime	2.25
Magnesia	3.51
Carbon dioxide	1.36
Combined water	5.50
Graphite, etc. (by difference)	10.80
	100.00

It can probably be regarded as a highly metamorphosed carbonaceous modification of the phyllite common to the country.

A special examination for elements that might be included in the 'undetermined constituents' in the above analysis (which term covers a small amount of arsenical pyrite) gave traces of lead and copper, no zinc, bismuth, molybdenum or chromium, 0.02% nickel, and 0.53% arsenic, as well as a trace (doubtful) of antimony. The heavy mineral constituents present—the sulphides—are clearly not responsible for re-precipitation phenomena, as is proved by the fact that concentrate from the ore, although difficult to treat by cyanide, does not re-precipitate gold from cyanide solutions.

The silica is, in part, easily soluble in solutions of alkali and alkaline carbonates. It was noticeable that, although cyanide solution filtered through the schist beds came off perfectly clear, the subsequent water-washes brought away a turbidity which, when settled out, appeared as a voluminous gelatinous precipitate consisting of silica 47.3%, alumina 35.1%, lime 10.5%, and magnesia 5.2%. The schist contains a small amount of magnesium sulphate, which can be extracted by water.

The carbon, which varies in quantity in different samples—running from 4% to as high as 10%—is distinctly graphitoid. It can be separated from the schist by fusing the latter repeatedly with caustic potash and treating with acid until the residual product is approximately pure carbon. This, when dried and pressed or rubbed, shows a true graphitic lustre.

This residual carbon can be easily and quickly (in a few hours) oxidized by treatment with chlorate of potash and concentrated nitric acid to a quasi-colloidal substance which differs from the products (humic acids) obtained by the oxidation of ordinary amorphous carbon in that it is of a light yellow color and is only soluble to a limited extent in water. The presumption therefore is that the carbon in the schist is of a graphitoid nature, probably a colloidal form of graphite. That it can be comparatively easily removed by roasting, in spite of its graphitoid nature, is probably due to its colloidal condition. It seems worth mentioning at this point that, when the ore is treated by roasting, the test to determine whether it is sufficiently well roasted to yield a good extraction is directed towards determining whether all the *carbon* has been got rid of. The presence or absence of carbon in the roasted ore is a conclusive indication of the quality of the roast from an extraction point of view.

Several hundreds of experiments were carried out with a view to finding some means of stopping the precipitating action of the graphitic schist. They were mostly of an empirical nature and were started primarily with the object of seeing whether the precipitating agent in the schist could be satisfied or 'pre-loaded' with some metal other than gold, or whether it could economically be destroyed by chemical means, or whether its action could be weakened by the presence of other substances in the cyanide solutions. These tests were applied:

1. By pre-treating beds of the schist with various reagents such as solutions of metallic salts, oxidizing agents, and other substances, and subsequently passing auriferous cyanide solutions through the pre-treated beds.

2. By adding to auriferous cyanide solutions various oxidizing and other reagents, and making comparative precipitation trials on the schist.

Among the reagents applied for pre-treatment were solutions of copper, silver, lead, mercury, platinum, tin and various iron salts, dilute nitric acid, varying strengths of alcohol, alkaline carbonate, cyanide and ferricyanide, barium peroxide, ammonium nitrate and nitrite, alkaline sulphite and bisulphite, alkaline sulphide, etc.

Some of the metals, notably silver and copper, were precipitated by the graphitic schist, the former, certainly in part, by replacing the manganese present. But both silver and copper were immediately dissolved on applying the auriferous cyanide solution and did not at all subsequently affect the amount or rate of precipitation of gold.

Among additions to the auriferous cyanide solution (without pre-treatment of the graphite) were copper, silver, lead, mercury, platinum, iron and cadmium salts, barium peroxide, potassium ferricyanide, cyanogen bromide, etc.

None of these substances was of the least avail in checking the rate of amount of precipitation of gold by the graphite: oxidizers such as cyanogen bromide seem rather to promote it.

A series of temperature tests over a fairly wide range of temperatures (from 7 to 30 C.) showed that the rate of precipitation is not affected by any variation in temperature within the limits stated.

The failure to detect, in the graphitic schist, any element likely to cause precipitation of the gold and the long list of negative results in pre-treatment and other experiments seemed then to necessitate a re-consideration of the possibility of an analogous action of the schist—considered simply as a carbonaceous substance—and of charcoal. There are undoubtedly remarkably few substances known, other than nascent hydrogen, or metals capable of producing nascent hydrogen, that will precipitate gold from cyanide solution without first destroying the free alkaline cyanide present. One of these few is charcoal, and it precipitates gold in quantities approximately of the same order of magnitude as the amount of gold precipitated by the carbon in the graphitic schist. For instance, in the example given at the beginning of this paper the gold precipitated represents about 0.22% of the amount of carbon present in the schist. Freshly ignited samples of charcoal give a precipitation of 22 to 24 mg. gold on 10 gm. of the charcoal under like conditions as to strength of solution and time of contact. So that a certain amount of analogy between the precipitating action of charcoal and of the graphitic schist is ready at hand.

Having regard to this possible analogy and as a preliminary to a further investigation of the action of the schist, it was thought worth while to study the effect of charcoal on auriferous cyanide solutions and, with a view to fixing a number of data relating to the precipitation of gold by charcoal, several series of tests were carried out, which will be dealt with below.

In every case the charcoal, crushed through a 10-mesh sieve, was immersed in the solution, without agitation, for the stated length of time.

(A). Precipitation with graduated cyanide strength. No free alkali.

10 gm. charcoal standing in contact with 200 c.c. KCN solution containing 21.6 mg. gold. Time about 16 hours.

The results are tabulated below:

Free NaCN in 200 c.c. solution, Gm.	Gold precipitated, Mg.	Gold adsorbed, Mg.
Nil ($NaAuCN_2$ only)	16.6	0.6
0.14	14.0	0.4
0.28	13.3	0.5
0.42	12.9	0.7
0.56	12.1	0.9

It will be seen that the precipitation is greatest where the cyanide strength is at a minimum, and with increased cyanide, from about 0.07% upward, decreases steadily.

The third column of figures in the same table represents adsorbed (as distinct from precipitated) gold. The figures for the adsorbed gold were arrived at as follows: Of the 200 c.c. solution applied to the charcoal in each test, exactly one-half was filtered off and the gold in it determined. The remainder of the solution was then passed through the same filter and the charcoal washed with a copious supply of water. The second half of the solution (plus washes) was then also assayed.

The second half of the partly precipitated solution in each case contained slightly more gold than the first half, showing that, by virtue of surface action, there is a small but distinct concentration of the soluble (and therefore presumably unchanged) gold salt on the charcoal. This concentration of salts in solution is an effect which, as will be noted from above series of tests, is different in nature and of a different order from permanent precipitation. The precipitation results are based on the amount of gold originally in the 200 c.c. of solution *minus* the amount contained in the whole of the solution and washes after precipitation.

(B). Precipitation with graduated alkalinity.

10 gm. charcoal standing about 15 hours in contact with 200 c.c. 0.28% KCN solution carrying 21.6 mg. gold.

Free NaOH in 200 c.c. solution, Gm.	Gold precipitated, Mg.
Nil	12.0
0.17	12.2
0.34	12.4
0.51	12.8
0.68	13.35

The estimation of precipitation with graduated alkalinity is based on the assay of the first half of the partly precipitated solution only and therefore includes adsorption. Probably the apparent slight differences in precipitation are merely due to different degrees of adsorption. It would appear probable also that the adsorption shown in the figures tabulated under *(A)* is an effect of the alkalinity of the cyanide solution and not of the cyanide *qua* cyanide.

(C). Precipitation with graduated gold content.

10 gm. charcoal standing in contact with 200 c.c. of solution containing 0.28% KCN and graduated amounts of gold, for about 15 hours:

Gold in 200 c.c. solution, Mg.	Gold precipitated, Mg.	Gold adsorbed, Mg.
2.16	2.08	0.08
5.4	4.28	0.02
10.8	7.4	0.20
16.2	9.75	0.45
21.6	11.29	0.9

In these tests the partly precipitated solutions were again assayed in two halves in order to arrive at a measure of the adsorption.

The precipitation figures in this table indicate that, as was to be expected, the absolute amount of gold precipitated increases with the increase of gold contained in the

applied solution, but that these increases are not proportional. The more gold there is in the solution the smaller the percentage of it which is precipitated in a given time.

(D). Precipitation with varying time of contact.

In this series a number of 10-gm. lots of charcoal were treated for varying lengths of time up to 48 hours with 200 c.c. 0.28% KCN containing 43.2 mg. gold (twice as much as in the previous tests), in the expectation that with this grade of solution the load-point would be reached within a couple of days.

It was found that the extreme time given was insufficient to exhaust the precipitating power of the charcoal, but the figures obtained are interesting:

Contact, hours.	Gold precipitated, Mg.	Contact, hours.	Gold precipitated, Mg.
3	14.0	18	20.6
6	16.2	24	20.8
9	18.0	36	22.0
12	19.6	48	24.2

It will be noticed that at from 18 to 24 hours the load-point appeared to have been reached, but at 24 hours and beyond, precipitation appeared to be resumed, much as if some secondary reaction had commenced. This interesting feature was not followed up, as, at the time the experiments were made, the object of the charcoal precipitation tests was merely to obtain a general idea of the factors affecting the action of the charcoal. The results of the experiments tend to show that, however the precipitating action of the charcoal may be accounted for, it is different in nature and degree from mere adsorption and that the amount of it is influenced by the proportion of gold present, the time of contact, and the strength of the cyanide solution. The amount of excess alkali present has little or no effect on the amount of precipitation. It has also been found a matter of indifference whether the gold in the solution has been dissolved from ore, or has been added as aurous cyanide or as auric chloride.

From a gold chloride solution, on which carbon acts chemically as a precipitant:

$$4AuCl_3 + 6H_2O + 3C = 4Au + 12HCl + 3CO_2*$$

the gold is quickly precipitated in visible metallic form on charcoal. The gold thus precipitated is readily soluble in alkaline cyanide.

The precipitation on charcoal from an auriferous cyanide solution is clearly of a different nature. For, in the first place, it is inconceivable that charcoal, *qua* carbon, can similarly act chemically upon a weak alkaline auro-cyanide solution. Secondly, the gold precipitated remains almost completely insoluble in fresh alkaline cyanide solution. And, thirdly, the most careful examination of the charcoal on which gold has been precipitated from cyanide solution fails to reveal the presence of any visible coating of gold.† These considerations suggested the idea that gold precipitated on charcoal from cyanide solution might be soluble in some practicable reagent other than cyanide, and a number of possible solvents were tried, keeping this contingency in view. After several fruitless endeavors the interesting discovery was made that a considerable proportion of the gold could be dissolved in solutions of alkaline sulphides. In a preliminary test a 10-gm. lot of charcoal, on which had been precipitated 10 mg. gold, was thoroughly washed, until the washings no longer gave a KCN reaction. The charcoal was then treated on a filter by passing through it 100 c.c. of 1% sodium sulphide solution and again washed. The filtrate and washings, on assaying, were found to contain 3.4 mg. dissolved gold.

The following tests were then made:

Five lots of charcoal, each 10 gm., loaded with gold varying in amount from 12 to 13.35 mg. were washed with 400 c.c. water to remove cyanide. Then treated by standing for 19 hours in contact with

	Dissolved Mg.	Out of Mg.
a. 200 c.c. plain KCN 0.28%	1.4	12.0
b. 200 " 0.14% KCN and 0.14% Na_2S	4.4	12.4
c. 200 " 0.28% Na_2S	8.0	12.4
d. 200 " 0.28% KCNS	0.3	12.8
e. 200 " 0.14% $NaHCO_3$ and 0.14% Na_2S	7.3	13.35

Two additional samples of 10 gm. of charcoal preloaded with 14.8 mg. and 17 mg. of gold respectively, well washed and treated (allowed to stand in contact) overnight:

a. With 200 c.c. 0.3% Na_2S solution.
b. " 200 " 0.3% NaHS "

The assays of the solutions showed that

a. Dissolved 13.1 mg. gold out of 14.8 mg.
b. " 12.4 " " " 17.0 "

It was then thought worth while to see whether an analogy proved to exist between the precipitating action of both charcoal and graphitic schist also applied to the re-solution of the precipitated gold. The following experiments were therefore tried to determine whether any re-solvent effect could be obtained by treating, with alkaline sulphide solution, samples of graphitic schist on which gold had been precipitated.

Two lots of the schist, each 250 gm., to which was added 1 gm. of lime, were each treated with 600 c.c. auriferous cyanide solution containing 10.8 mg. gold per 100 c.c. The solutions were slowly passed through the bed of schist eight times.

	Gave Mg.		Mg. Pptd.
100 c.c. from No. 1 after precip'n	2.4	=	50.4
100 " " No. 2 " "	2.5	=	49.8

The No. 1 bed was then drained dry and treated, without washing, with 500 c.c. Na_2S solution 0.3% for 24 hours. It was then washed and the whole of the sulphide solution and washes assayed. The gold obtained weighed 37.3 mg. As the graphite bed was not washed previous to sulphide treatment, this does not all represent re-dissolved gold, but is made up as follows:

Adsorbed gold (based on the result of a previous test)	8.0
Absorbed in 130 c.c. solution at 2.4 mg. per 100 c.c.	3.2
Actually re-dissolved	26.1
	37.3

*Avery.

†This is contrary to the observation recorded by Morris Green. (Trans., I. M. & M., Vol. XXIII, p. 65.)

No. 2 bed was well washed to make sure of getting rid of all KCN. The bed was then treated overnight with a weak solution of H_2S. This solution dissolved 11.2 mg. gold.

Four beds of graphite were then charged with gold, well washed, and treated with sulphide solution by passing the same through slowly, 9 times in about 16 hours. The beds were again thoroughly washed and the solution and washes from each bed assayed. The following are the results:

	Gold contained, Mg.	Treated with C.c.		Gold dissolved, Mg.
No. 1	39.6	500	0.2% K_2S	22.0
No. 2	38.8	1000	0.1% "	31.6
No. 3	38.8	500	0.4% "	31.0
No. 4	40.0	500	0.29% KHS	30.0

The highly interesting fact is therefore established that the gold precipitated from cyanide solutions on charcoal as well as on graphitic schist is, to a considerable extent, soluble in alkaline sulphide solutions. Why it is not completely soluble and what the best conditions are for effecting the re-solution (why, for instance, less should have been re-dissolved from No. 1 bed as above than from any of the others) are points still requiring elucidation.

By a series of experiments it was found that both charcoal and the carbonaceous schist, when loaded with gold to a point at which precipitation stops, or is greatly retarded, and then treated with alkaline sulphide to dissolve the gold, recover practically all their precipitating power. (It had been noticed that a pre-treatment of charcoal or graphitic schist with weak alkaline sulphide solutions rather tends to promote the precipitating action than to weaken it.)

The analogy between the precipitating action of the West African carbonaceous schist and ordinary wood-charcoal, both being in contact with auriferous cyanide solutions, may now be summarized as follows:

1. Gold is precipitated (in the case of the schist in a measure roughly proportional to the amount of carbon present).

2. The gold thus precipitated is not soluble to any appreciable extent in fresh cyanide solution.

3. It is to a large extent soluble in alkaline sulphides.

4. After dissolving the gold in alkaline sulphides the precipitating capacity of both schist and charcoal is renewed practically in its entirety.

The analogy, it will be seen, is a close one: so close as to justify the assumption that any explanation of how and why the gold is precipitated by charcoal will throw a light on the action of the graphitic schist.

In considering in what form the gold is precipitated by charcoal from cyanide solutions it is necessary, in the first instance, to repeat that, according to all the evidence, the action is a quite different one from the precipitation of gold from gold chloride solution:

(*a*) Charcoal rapidly and *visibly* precipitates *metallic* gold from gold chloride solution in a form in which it can readily be dissolved in weak cyanide solutions, but in which it is quite insoluble in alkaline sulphide solutions.

(*b*) From alkaline aurous cyanide solutions of equal value the gold is comparatively slowly precipitated in a form which is not visibly metallic (indeed there is no visible coating of the charcoal of any sort). Gold so precipitated is not soluble, except for an insignificant fraction, in fresh cyanide solutions, but is to a considerable extent soluble in alkaline sulphide solutions.

The charcoal containing gold precipitated from cyanide solution can, by careful washing, be fairly rapidly freed of the last trace of alkaline cyanide, but it is found that traces of cyanogen still persist in the wash-water for a long time after the soluble alkaline cyanide has been removed. This may be due to the dissolving of cyanogen gas occluded in the charcoal or to the slow decomposition of an insoluble cyanogen compound.

When the 'loaded' charcoal, after careful washing, is treated with a solution of alkaline sulphide to dissolve the gold, the resultant auriferous solution is found to contain a quite noticeable amount of cyanogen as sulphocyanide, in quantity not apparently in any fixed relation to the amount of gold present, but in considerable molecular excess of same. In one case, for instance, when a sample of 'loaded' charcoal was treated with two successive lots of Na_2S solution, and these solutions were assayed, and, after eliminating the excess of sulphide, roughly tested for sulpho-cyanide (by colorimetrical estimation as ferric sulpho-cyanide), it was found that they

a. Contained, per 100 c.c., 3.54 mg. gold and NaCNS equivalent to 12 mg. cyanogen.

b. Contained, per 100 c.c., 1.2 mg. gold and NaCNS equivalent to 6 mg. cyanogen.

The following further interesting facts were observed, which appear to apply equally to gold precipitated on charcoal or on graphitic schist:

1. H_2S, K_2S, Na_2S, KHS, and NaHS all act as solvents for gold precipitated from cyanide solution on charcoal or graphitic schist, and all about equally well molecule for molecule. Alkaline polysulphides are less effective solvents, and ammonium sulphide still less, although these also give rise to the formation of alkaline sulphocyanide.

2. The gold dissolved by the alkaline sulphide solution is not precipitated by lead carbonate or by manganese peroxide, but is precipitated on metallic copper and to some extent on zinc and aluminum. (A solution of potassic-aurous sulphide is very completely and rapidly precipitated by either of the two first-named reagents.) The gold is therefore evidently not dissolved as a double sulphide, as at first seemed possible, but as an alkaline aurous-cyanide. Neither sodium thiosulphate nor alkaline thiocyanates, it may be mentioned, dissolve the gold from charcoal.

It is not necessary to go beyond the established fact that gold precipitated upon charcoal from cyanide solutions is practically insoluble in fresh cyanide solutions and *is* soluble in alkaline sulphide solution to arrive at the conclusion that this gold is not in metallic or col-

loidal metallic form, but is held in chemical combination. The question of *what* the chemical combination is, affords room for a great deal of, possibly, unprofitable surmise. it is, however, interesting to consider what elements or radicals are available for such combination.

1. Although the alkaline aurocyanide is undoubtedly split up, the aurous cyanide is probably not decomposed or metallic gold would be deposited. Possibly such decomposition takes place to a slight extent in time, and this may account for the small fraction of precipitated gold which becomes soluble in cyanide after the charcoal or schist bed has been drained and washed.

2. Cyanogen in considerable molecular excess of the precipitated gold is occluded* by the charcoal (which will occlude a larger volume of cyanogen than of almost any other gas). How this cyanogen is liberated from the cyanide solution is an obscure feature which is worth considering. When cyanogen gas is passed into caustic alkali solution it forms alkali cyanide and cyanate:

$$C_2N_2 + 2KOH = CNOK + CNK + H_2O\dagger$$

Possibly the adsorptive effect of the charcoal is sufficiently strong to cause a reverse action, and to cause the cyanides and cyanates to interact with liberation and immediate adsorption of cyanogen. (Some small amount of cyanates is present in all cyanide solutions after exposure to the air or after subjection to oxidizers.) A more probable explanation is, perhaps, that the HCN formed by hydrolysis is partly oxidized by the oxygen occluded in the charcoal. The action could be represented thus:

$$2HCN + O = C_2N_2 + H_2O$$

By whatever process it may get there, there is no doubt that cyanogen, whether as adsorbed gas, or in combination, or in both states, is retained by charcoal which has been used to precipitate gold from cyanide solution, long after the more freely soluble cyanides are removed by washing. Owing to its being apparently in considerable molecular excess of the precipitated gold, it is impossible to draw any definite conclusion as to its function in the precipitating action, but the fact that it is available has to be taken into account.

3. Morris Green in his paper, previously cited, has made out an excellent case for CO being the prime precipitating agent in charcoal. (If this is so in the case of charcoal, there is no inherent improbability in it also being so in the case of the graphitic schist referred to in this paper, as the schist contains colloidal matter which acts as an adsorbent, even if the graphitoid carbon present did not fulfil such function). CO gas *per se* does not precipitate gold from cyanide solutions, but when it acts as adsorbed gas in charcoal, other factors come into play—of which the ruling one is not improbably the simultaneous presence of adsorbed cyanogen gas.

Having regard to the considerations enumerated above it would not appear an unreasonable or far-fetched suggestion that the gold compound held in the charcoal may be a combination of AuCN, CO, and C_2N_2—a carbonyl aurocyanide, possibly on the model of one of the carbonyl platino-chlorides, of which several are known.

Adopting as a working hypothesis the formula $AuCN.CO(CN)_2$ the process of dissolution of the gold in alkaline sulphide could be represented:

$$AuCN.CO(CN)_2 + Na_2S = NaAu(CN)_2 + NaCNS + CO$$

the CO being re-adsorbed and the precipitating power of the charcoal being renewed (as, in great part, actually happens). Against this hypothesis there is the fact that the re-solution of the precipitated gold in alkaline sulphide is never a complete one and is generally under 75%, which would rather indicate that the action is not so simple as the above equation would make it appear.

In closing I summarize my conclusions:

1. It has been demonstrated that the graphitic schist of West Africa precipitates gold from auriferous cyanide solution in a manner which is, in all important respects, analogous to the action of charcoal under like conditions.

2. The gold is precipitated on the charcoal (and on the schist) not as metal but as a compound—possibly a carbonyl aurocyanide.

3. The gold compound is decomposed and the gold dissolved to a considerable extent by alkaline sulphide solutions (judging by the results of a large number of tests, of which only a few have been included in these notes, the re-solution is effected rather more easily from the schist than from charcoal).

Whether the discovery that alkaline sulphide solutions will dissolve gold which has been precipitated on the carbonaceous schist can be turned to practical utility in the cyanide treatment of ores containing such schist, is the subject of experiments at present being carried on. By post-treating, with sulphide solutions, sand residues from which a maximum possible extraction had previously been recovered by cyanide treatment, a further extraction has been obtained from a large number of samples, and there is some promise that an economical post-treatment may be evolved on these lines. The precipitation of the gold from the sulphide solutions (in which the gold is held as alkaline aurocyanide with hardly any free alkaline cyanide, but a large excess of alkaline sulphide) appears to be best effected by contact with metallic copper.

*The author appears to use 'occlude' and 'adsorb' synonymously.—EDITOR.

†Roscoe & Schorlemmer.

ADSORPTION is the name applied to the phenomenon exhibited by colloid substances, which are able to take dissolved substances out of solution and hold them, often with great tenacity. Some substances exhibit selective adsorption; thus seaweed adsorbs iodine from sea-water, although the quantity present is so small that it cannot be detected by any of the usual tests. Adsorption is a surface tension phenomenon; increased concentration of the adsorbed surface on the boundary of the colloid particle leads to decreased surface tension. In a few cases increased concentration leads to increased surface tension, and negative adsorption is then exhibited.

Goldfield Re-visited—I

By T. A. RICKARD

Seven years ago I made my first visit to Goldfield; it was warm then, warm with sunshine and prosperity. When I went there the other day the snow had been falling over-night, it was still falling, and the temperature was low. The air was cold and I met many people with cold feet. Goldfield has abated its exuberance of spirit and it has shrunk in size, so that it looks like a fat man who has taken the cure. The clothes of its prosperity are too ample for its severer shape. Empty houses are pitifully conspicuous. The population in 1908 was 22,000; now it is 4500. Last year it was fully 1000 less; prospects are improving; that is why it was pleasant to go to Goldfield at this time.

THE JUMBO EXTENSION MINE, GOLDFIELD.

Jumbo Extension is the main subject of talk: rich ore—and litigation. Apparently a mine must pass through the whooping cough of a lawsuit before it reaches the adult stage of development. I saw the rich ore and heard all about the disputes concerning the ownership of it. Naturally, I did not hear all that has been said on the subject, but enough to outline the story to my readers.

The Jumbo Extension property consists of two claims, the Polverde and the Velvet. Of these two the Velvet was acquired on October 5, 1914, from the Merger Mines company, owning adjoining property. The Merger Mines had failed to find any ore despite exploratory work begun in 1911 and reaching to 1772 ft., the maximum depth attained in the district. In order to assist further exploration in its Velvet claim, the Merger Mines leased the Jumbo Extension shaft in December 1912. Some low-grade ore was found, but nothing particularly encouraging. To obtain further funds, the Merger Mines then gave an option on its Velvet claim to the Jumbo Extension company, which exercised the option, as stated, in October last. This transaction might have caused no comment if immediately thereafter the Jumbo Extension company had not uncovered rich ore in the lode already cut in the Velvet claim. Shares that had been peddled for 12 to 15 cents during the major part of 1914 rose to $4 on November 30. They have not been anything like so high since, although a great deal more ore has been uncovered; but that is another story. No sooner had the discovery been heralded than the minority shareholding in the Merger Mines brought suit against the directors of that company, alleging collusion and fraud in the sale of the Velvet claim to the Jumbo Extension company. On February 21, 1915, a receiver was appointed, pending a suit to annul the deal with the Jumbo Extension company. Three days later the Reorganized Booth Mining Company, owning the Booth claims, filed an apex suit against the Jumbo Extension and the Merger Mines.

To explain this, let me refer you to the accompanying map of the territory in dispute. It will be seen that the outcrop of the rich lode traversing the Goldfield Consolidated property is shown as if it made a curve northward so as to pass through both end-lines of the Booth claim and appears to give the owner of that claim the apex rights on all ground within the end-lines projected forward in the direction of the dip of the vein. However, lodes are rarely as continuous in strike or as simple in structure as they are portrayed on maps. It is a moot question whether the vein in the Booth is an uninterrupted extension of the vein in the Red Top claim of the Goldfield Consolidated. Good evidence exists for suggesting that a fault intervenes. The vein has a flat dip, ranging from 35 to 50° east, and averaging about 40°. Geologically the Merger Mines at a vertical depth of 1750 ft. is at the same horizon as the Booth at 500 ft., although the distance between them is 3000 ft. as measured on the surface. Hence the legal ownership of ore found in the Jumbo Extension, Kewanas, and Merger Mines is threatened by the Booth apex. Before this recent entanglement supervened the Goldfield Consolidated company had entered into a mutual side-line agreement with the Jumbo Extension and the Merger companies, that is, each had waived any legal right to

extract ore beyond their side-lines vertically projected. They agreed mutually to waive any extra-lateral rights. That agreement was renewed after the Velvet was added to the Jumbo Extension property. The Booth gave a side-line waiver to the Goldfield Consolidated as late as April 24. Now comes the humor of the position. Mr. George Wingfield is the president of the Goldfield Consolidated; he is the controlling shareholder also in the Merger Mines, and he is the owner of the Booth. He is he Pooh-Bah of the comedy. As controller of the Merger he permits the sale of the Velvet claim by the Merger to the Jumbo Extension; then, having placed the proceeds from this sale into the empty treasury of the Merger company, he and his friends are attacked by the minority shareholding in the Merger; whereupon he springs the Booth apex-suit upon them and upon the Jumbo Extension company. Both the Merger Mines and the Jumbo Extension were placed in the hands of a receiver. An examination of the geological evidence in the case was made by Messrs. H. V. Winchell, J. R. Finlay, and Frank W. Royer, who reported to the attorneys of the Jumbo Extension company, and these in turn joined with the mining experts in recommending a compromise. A consolidation of the Booth, Jumbo Extension, Kewanas, and Merger was discussed, but the idea did not find sufficient support. Finally an arrangement was formulated whereby the Jumbo Extension is to increase its capital stock from 1,250,000 shares to 1,750,000, and of this amount is to pay the Booth 300,000 shares for a side-line agreement. This proposal is to be submitted to a meeting of the Jumbo Extension shareholders on May 20, while the formal meeting of the Booth is scheduled for May 31.

Meanwhile, on May 5, the Kewanas company paid the Booth—that is, Mr. Wingfield—250,000 shares for immunity from apex demands, and the Kewanas Extension was given the same side-line agreement for 25,000 shares of its capital stock. On May 6 the receivership in the Merger case was made permanent and announcement was made before the United States Court at Seattle that suit would be brought against the majority directors for unauthorized transactions, notably the sale of the Velvet claim to the Jumbo Extension company. The assertion is made that "the policy of all the business of the Merger company has been planned and carried out by the officers and persons who dictated and directed the policy and business of the Goldfield Consolidated company and allied concerns, and not by the trustees of the Merger company." On May 11 the Court authorized the bringing of a suit by the receiver for the recovery of the Velvet claim and for the value of the ore extracted by the Jumbo Extension company. From what I could learn at Goldfield, the deal between the Merger and the Jumbo Extension was a straight transaction. The Merger needed money badly, the Velvet claim apparently had no special value, and the sale would have escaped criticism if rich ore had not been found, subsequently, in the Velvet. The only complication arises from the fact that Mr. H. O. Whittemore, a Merger director, had caused Mr. E. S. Van Dyke, a former manager of the Jumbo Extension and the person who steered the deal, to give him 10,000 shares of Jumbo Extension out of a commission of 21,000 shares received by Mr. Van Dyke from the directors of the Merger. Even this need have excited no suspicion if a rich orebody had not been discovered so soon afterward in the Velvet workings. While the original complainant was a lady shareholder, Mrs. Lucy V. S. Ames, the chief opponent of Mr. Wingfield is Mr. John Erikson, of Seattle. He is a Swede who made about $200,000 at Nome, in Alaska. When he spent his money in buying tide-lands near Seattle he was supposed to have been victimized, but the extension of the Chicago, Milwaukee & Puget Sound Railway caused the land to become exceedingly valuable as an entrance into Seattle, so Mr. Erickson made a big fortune by selling it. Part of the friction at Goldfield is imputed to an old quarrel between Messrs. Erickson and Wingfield. It may be asked why the Goldfield Consolidated, at the instance of its president, Mr. Wingfield, did not finance the Merger Mines and so save the loss of the Velvet claim? The Consolidated had already put $250,000 of its money in the Merger and could well have afforded to risk $100,000 more, rather than lose the Velvet. This question is not unfair, having regard to the further fact that the Consolidated has seen fit to go outside the district, to Aurora, in order to extend its mining activities.

If the reader will now turn to the map he will see that the Florence appears to apex the Atlanta and Merger properties. Mr. Wingfield controls the Atlanta. Here is another complication. The apex rights of the Booth will clash with the similar rights of the Florence, but the prior privilege goes to the older claim. Herewith I give the names, numbers, and dates of location of the oldest claims in this vicinity.

Name.	Number.	Date of location.
Booth	2431	May 10, 1903
Florence	2357	May 19, 1903
Red King	2361	May 19, 1903
Combination	2375	May 26, 1903
Red Top	2217	Aug. 20, 1903
Mohawk	2283	Aug. 20, 1903
Miss Jessie	2564	Aug. 29, 1903
Velvet	3843	Sept. 1, 1903
Polverde	3626	Oct. 17, 1903

These incidents should go far to emphasize the absurdity of the apex law and the possibility of its use to destroy the equity acquired by discovery and development. To lay claim to the ore in the Jumbo Extension, the Booth has to jump across half a mile of ground, that is, over the intervening property of a third company in the face of an agreement waiving apex rights with that company. The Booth then extends the shadow of its apex farther along the dip over the Merger property, to be met there by the shorter shadow of a similar right thrown forward from an outcrop that is at right angles to that traversing the Booth.

Of course, this hurts legitimate mining—and the illegitimate also, for that matter. In January last a

dozen companies were ready to undertake a campaign of deep mining, encouraged by the discoveries in the Jumbo Extension, when the fiasco put an end—temporarily—to such projects. Jumbo Extension shares have fluctuated widely, as the following figures show:

Nov. 30	$4.05	April 22	$1.82
Feb. 24	0.51	May 11	0.92

The company has 1,250,000 shares. Dealings are mainly at San Francisco, but also on the New York exchange. Goldfield has no exchange, but it has several brokerage offices, where quotations are chalked on big boards. It is curious to find them open at 7 a.m., for they try to synchronize their business hours with New York. When it is 10 a.m. on Manhattan island it is 7 a.m. on the Nevada desert. Before the discovery was made, in October, the shares of Jumbo Extension were quoted at 12 to 15 cents. Many local people bought at these low prices and stood to make a nice 'clean-up,' but they used their profit to buy more stock, they 'pyramided,' forecasts being freely made that the shares would rise to $10. Some of the wiser miners gave orders to sell at $3, if the market declined. Their orders took effect automatically when the range of prices fell between $3 and $3.15 on December 28. Simultaneously a New York curb broker, then at Goldfield, circulated a report that the men at the mine were selling and that the mine was no good. Whereupon a small panic ensued. From $3.15 the market broke in a few days to 50 cents. Short-selling by brokers and by miners was influential in causing this debacle. Buying by New York helped to restore the quotation to a more reasonable figure. What the mine is worth is not known. Two experienced engineers have appraised the ore exposed, but the orebodies have not been uncovered as yet to the point where safe estimates are practicable. The ore is rich and there is a good deal of it, as will be indicated in my next article.

MAP OF THE CENTRAL PORTION OF THE GOLDFIELD DISTRICT.

SUPPLIES used at the low-grade mill at the Nipissing mine in 1914 were as follows: cyanide, 5.331 lb. per ton; lime, 5.749 lb.; caustic soda, 3.059 lb.; aluminum dust, 0.592 lb.; aluminum plates, 0.529 lb.; aluminum ingots, 0.172 lb.; flint pebbles, 3.826 lb.; coal for heating, 32.001 lb.; and power, 53.889 kw.-hr. The cost was $2.0457 per ton. In treating 79,125 tons the recovery was 89.64%, at a total cost of $3.989 per ton.

The Sapphire Mines of Yogo, Montana

By O. W. FREEMAN

Sapphire, one of the gem varieties of corundum, is composed of alumina, Al_2O_3, and is typically of a blue color; the cause of the color is not known but probably is due to the presence of extremely minute quantities of foreign material, such as a salt of iron.

Placer deposits in Burma, Siam, and Ceylon formerly were the greatest source of sapphires. These have furnished many stones of that rich deep-blue color for which the Oriental sapphire is noted. Now, most of the world's output comes from Montana, which has the largest and most productive mines in the world. The only locality where sapphires are mined from the rock in which they originate is in southwestern Fergus county, about 55 miles from Lewistown and 13 miles from Utica. These mines occur in a basin in the foot-hills of the Little Belt mountains, the sapphire-bearing rock extending across Yogo creek.

Systematic mining for sapphire in the United States has only been undertaken in Montana. A number of localities have been productive, the first stones being found about 1873 in the gravel-bars on the Missouri river, east of Helena, by miners in search of placer-gold. Actual mining, however, was not undertaken until 1891, when a number of companies were organized to work these bars for sapphire, but the production was never large and has nearly ceased in recent years. The sapphire has been discovered in placer deposits along Rock creek, in Granite county. These are worked by hydraulic mining and sluicing. Production started in 1899 and still continues. In some other prospects in Granite county sapphires have been found weighing as much as 7 to 8 carats; they have been discovered also along Dry Cottonwood creek in Powell county in 1889 and have recently been recovered by dredging. The successful exploitation of these deposits has been hindered by the color of the stones, which are most frequently of a pale greenish or greenish-yellow, varying in the case of the Rock Creek sapphire to darker shades of green and blue-green. Some red, pink, orange, and yellow gems have also been found. The source of most of the Montana sapphire, and practically all that has a deep-blue color, is from Yogo. Sapphires were first found here over twenty years ago by men engaged in placer-gold mining. An expensive ditch had been built to work the placers but the gold obtained did not suffice to pay the expense of operation. However, with the gold collected in the sluices there were found many hard blue stones, later identified as sapphire. The dike from which the gem-stones had come was discovered in 1896.

The Yogo sapphire occurs as disseminated crystals in an almost vertical dike of igneous rock, analogous to lamprophyre, 8 to 20 ft. thick, and of unknown depth. This dike has been traced by pits for over six miles. The dike-rock weathers easily to a soft, clayey material; hence no solid outcrops of it remain. Since the adjacent limestone was too hard for gophers to penetrate, the course of the dike was marked by their heaps of earth; this fact aided the early prospectors in locating their claims; many fine sapphires were picked up from these gopher dumps. Underneath the soft oxidized yellow clay the dike-rock seems to consist of three kinds, a reddish rhyolite, a porphyry, and a dark rock resembling diabase that disintegrates easily. Much of the rock has an uneven to conchoidal fracture that greatly aids in the disintegration of the rock. Most of the sapphire is found in the soft dark-gray rock, which looks to be worthless, for rarely can any sapphire be seen in the matrix when it is mined. The stones are of a dull lustre when found and generally have a rhombohedral form, in this respect contrasting with those from near Helena, which are usually more prismatic in habit. The crystal faces are often etched and striated. Several other dikes occur near the sapphire-bearing one, including one of almost identical composition only about 600-ft. away, yet no sapphire has ever been discovered in place outside of the one dike, although prospecting has been diligent.

Formerly there were two large companies operating mines on the sapphire-bearing dike, the Yogo American Sapphire Co. and the New Mine Sapphire Syndicate, a British corporation. In August 1914 the New Mine company purchased all the claims and assets of the American concern for $80,000; thus giving an English syndicate the practical monopoly of sapphire-mining in the world.

Originally the dike-rock was mined directly in open pits, now the mining is done through a shaft and by drifts, as in ordinary metal-mining. The dike-rock is broken by blasting, if necessary, and is so soft that many of the drill-holes are bored with augers. Entirely different methods are in use at the two mines for the extraction of the sapphires themselves from the broken material.

At the American mine the sapphires are removed from the matrix in a concentrator. The material is first sent through grizzlies, with spaces three inches apart, large lumps being broken with sledge-hammers. The broken rock is then conducted into trommels revolving in water; the shaking, combined with the action of the water, loosens the gem-stones, which drop through the openings along with some pyrite and other hard waste. They go to shaking-screens, which grade the material as to size. The largest and hardest pieces of rock are piled on a dump where they are left until weathering has disintegrated them, and are then subjected to the same process as the fresh rock. The finer material after screening is conducted to different jigs, depending upon its size, to be concentrated. Any large pieces of waste rock remaining

are removed by hand, and the pyrite is then removed from the concentrate by an electrostatic separator.

The process used in extracting the sapphire at the New Mine is even more interesting, as it is a curious combination of the methods in use at gold placers and the South African diamond mines. No crushing is employed for fear of breaking the larger crystals. The rock from the mine is dumped on large wooden floors. Here it is left

THE WEATHERING-FLOOR AT THE AMERICAN MINE.

to disintegrate by weathering, assisted by frequent wetting. Next it is shoveled into sluices, in which riffles are placed. The sapphire being heavier than the matrix is caught in these riffles and is daily removed by turning off the water and lifting the racks. The rough concentrate is then cleaned in a jig. The rock that has passed over the riffles is dumped on a second wooden floor and allowed to weather further, after which it is again sent through the sluices to separate the dirt from the sapphire. This process is repeated four times in all before the rock is finally rejected, but by far the greater quantity of sapphire is recovered from the first two floors. Many stones, especially the smaller ones, are not recovered by this sluicing system; in fact, it has been estimated that only 75% of the sapphire is recovered by the sluicing system, while practically all of the large and 95% of the smaller stones are recovered in the mill of the American mine.

MEN AT WORK ON THE SECOND WEATHERING-FLOOR.

The annual output of sapphire from Yogo amounts to about 90,000 oz., or nearly three tons. In 1912 the value of the rough gems produced in Montana, mostly from Yogo, was $200,585. A large proportion of the stones were culls, either too small or too imperfect for gems. These are used for watch-jewels, meter-bearings, phonograph-points, etc. Most of the sapphire is sold in London, and smaller amounts in New York and Paris; practically none has been sold directly to local buyers. The gems are cut and polished in Europe, many of them in Switzerland, it being cheaper to have the work done abroad and pay an import duty of 20% under the Underwood tariff than to have it done in America. The European war has seriously interfered with shipments to London, so that the present sapphire-mining is at a minimum.

Some cutting and polishing was formerly done at the American mine. It is interesting to watch a dull stone turned by the skillful workman into a beautiful gem. The sapphire is cemented to an adjustable handle, that can be accurately and quickly changed by the operator, so that any face or angle of the gem can be ground or polished. Grinding into the desired shape is done on a brass jewelers-wheel, covered with diamond dust; polishing is done on another wheel covered with diatomaceous earth. The sapphire crystals tend to be so flat that there is an average loss of two-thirds their weight by cutting.

Sapphire is commonly considered to lose its beauty by artificial light and is essentially a daylight stone. Most sapphires from the Far East do lose much of their brilliance at night, but the Yogo sapphires are of an exceptional clear deep blue and retain much more of their splendor by artificial light. The largest sapphire found at Yogo weighed 19 carats in the rough and 8½ carats when cut. A 1-carat cut sapphire brings from $30 to $60. Much larger sapphires have been found in Burma and India.

"The occurrence of the sapphires shows conclusively that they were formed in the dike rock itself. Their origin is believed to be the result of the action of the molten igneous rock upon the fragments of clay, shale or impure limestone, taken up by the former in its ascent. This implies the complete assimilation and digestion of

such material in the igneous rock. It is apparent from a study of the sapphires themselves that they crystallized out of the rock, but it is also evident that partial absorption took place before final consolidation, since many of the sapphires show deeply corroded surfaces; others are rounded masses whose crystalline outline is nearly effaced, while many of them are surrounded by a blackish crust. If the molten rock could dissolve the sapphires at this stage it certainly could dissolve clay shale as well. The dike undoubtedly extends a considerable distance in depth."* From a comparison with other dikes nearby composed of the same material, it is believed that the lamprophyre dike was originally too deficient in aluminum for sapphire to be formed. However, at a depth of over 1000 ft. there is a wide variety of calcareous, siliceous, and argillaceous rocks that could furnish abundant aluminum-bearing material to the molten rock as it ascended. The clear-cut crystals, and the general distribution of the sapphire also, show conclusively that they have been formed by crystallizing out of the magma.

Costs at the South Kalgurli

This property and mill are at Kalgoorlie, Western Australia, and the last annual report gives the following data:

	Cost per Ton		
Development:		Agitation	$0.38
Ordinary	$0.50	Filter-pressing	0.28
Hainault mine	0.23	Clean-up	0.08
		Disposal of residue	0.10
Total	$0.73		
Ore extraction:		Total milling	$2.34
Breaking ore	$0.98	General expenses:	
Filling stopes	...	Salaries and wages	$0.10
Tramming and hoisting	0.67	Sundry	0.02
		Maintenance and supplies	0.01
Total mining	$1.65	Rent and insurance	0.05
Ore treatment:			
Rock-crushing	$0.05	Total general	$0.18
Ore transport	0.03	Bullion realization	0.02
Ball-milling	0.60		
Roasting	0.60	Grand total	$4.92
Grinding-pans	0.22		

Development totaled 5036 ft. The mill treated 124,670 tons of ore averaging $5.30 per ton. A dividend of $29,700 was paid.

Lead and Zinc Smelting in Australia

At meetings of the Broken Hill Proprietary and Broken Hill South Silver Mining Co. in Melbourne, Australia, on February 26, official statements were made that "a basis has been found for the purchase and future operations of the Port Pirie smelting works which is mutually acceptable to the Broken Hill Proprietary Co., Ltd., the Broken Hill South Silver Mining Co., N.L. and the North Broken Hill, Ltd." This basis provides for the future operation of the works on generally co-operative lines, according to the *Mining Standard*. A detailed scheme is at present being prepared, and, until finally accepted by the three companies, will not be binding. The probability is that the scheme will take the form of a new company, the shares of which will be proportionately held by the three companies concerned. It is not improbable, however, that other companies may be allowed to participate and so make it cover the entire smelting interests of the Barrier (Broken Hill). The importance of this step can hardly be overestimated, as, if fully effective, it will eventually enable the whole of the zinc and lead concentrates of that district to be dealt with in Australia, instead of being sent to Europe for treatment.

*Weed, 20th Annual Report, U. S. G. S., Part 3, page 458-459.

Copper Exports From Japan

The influence of the War upon the copper industry is no small matter in Japan, as the exports of copper have been reduced to about one-half the amount before the War. The following statistics show the facts:

Exports of Copper from Yokohama

1914.	Pounds.	1914.	Pounds.
July	2,502,424	November	1,124,125
August	378,637	December	5,069,885
September	316,800		
October	1,274,388	Total	10,666,259

The exports of copper from Yokohama in the first half and second half-year of 1914 were:

1914.	Pounds.
January-June	19,671,154
July-December	10,666,260

Exports of copper in the five months (August to December, 1914) were made to the following places:

	Pounds.
Various Eastern ports	1,252,260
London	1,556,984
New York	1,635,880
Vladivostok	3,830,704
Total	8,275,828

Antimony ores are of common occurrence in New South Wales, and are distributed over widely separated areas. The principal ore is the sulphide, known as antimonite, antimony, glance, or stibnite, and it occurs most generally in lodes with a quartz gangue intersecting paleozoic sedimentary rocks, as well as granite and other igneous rocks. Frequently the most productive lodes are found in sediments near their junction with intrusive granites. The association of gold with antimony ores is a noteworthy feature of some of the state's productive lodes, particularly so at Hillgrove near Armidale. The most important molybdenum ore is molybdenite. An oxide of molydbenum and a molybdenite of lead occur in New South Wales. Molybdenum occurs in this state in certain silicious granites, near their margins, or zones of contact with other rocks. The molybdenite deposits have a peculiar appearance and are to be found in 'pipes' or 'chimneys.'

Costs at the Commonwealth Mine

This property is at Pearce, Arizona, and the following figures cover the period from May 1 to December 31, 1915, when 70,650 tons of ore was mined and treated:

Direct cost:	Per ton.		Per ton
Mining	$0.954	Legal	0.007
Development	0.235	Safety	0.001
Milling	1.879	Mill tests	0.002
Maintenance	0.090	Pumping mine water	0.128
Marketing	0.087		
General expense	0.152		$0.266
	$3.397	Total operating costs	$3.663
Indirect cost:		Shaft-sinking, etc.	0.208
Fire insurance	$0.054	Construction, etc.	0.179
Liability insurance	0.066	Interest	0.265
Taxes	0.005		$0.643
Water	0.003	Total expenditure	$4.306

Mining and development costs were as follows:

Items of cost.	Mining.	Development.
Ore breaking	$0.416	$0.149
Tramming and shoveling	0.217	0.038
Timbering	0.101	0.004
Hoisting and dumping	0.090	0.015
Foremen and bosses	0.033	0.008
Assaying and sampling	0.044	0.001
Tool sharpening	0.022	0.007
Mine machines	0.014	0.005
Surveying	0.007	0.008
General expense	0.010	....
Total	$0.954	$0.235

Of the total of $67,433 for mining, labor cost $49,416; supplies, $14,282; electric-power, $1257; and steam-power, $2478. And of the development total of $16,621, the charges were $11,473, $4037, $168, and $943 respectively.

Treatment costs were as under:

	Per ton.		Per ton.
Crushing and conveying	$0.079	Precipitation	$0.116
Elevating and separating	0.060	Agitating	0.296
Sampling	0.021	Refining	0.043
Stamping	0.231	Pumping solution	0.051
Re-grinding (Hardinge)	0.311	Mechanical department	0.049
Re-grinding (tubes)	0.339	Water	0.012
Settling	0.118	Assaying	0.013
Filtering and discharging	0.113	Superintendence	0.027
		Total	$1.879

The total expenditure in the mill was $132,726, of which $28,300 was for labor, $50,195 for supplies, $48,001 for electric-power, and $6229 for steam-power.

Oil Refineries at Kurokawa, Akita-ken

A large flow of oil in Kurokawa village, Akita-ken, last year led the Nippon Petroleum Co. to build a new refinery there. After much investigation the company decided to build a refinery with modern machinery of Russian make. The company has sent an engineer to Petrograd, who will return to Japan in April with the required plant and a Russian engineer, who will supervise the erection. Meantime the Hoden Petroleum Co. is putting up a new refinery of nearly the same size with machinery of the American continuous type. The Nippon Petroleum Co. expects to secure better results in refining with Russian machinery because the oil from Kurokawa much resembles that found in Russia. Which of the new refineries will give better results will be known after they have been put into operation. In any case the oil-refining capacity of Japan will be greatly increased.

Experiments on Copper Ores by the Phelps-Dodge Companies

The annual reports of Phelps, Dodge & Co.'s subsidiary companies contain the following notes on experimental work done to improve the recovery of metals:

Copper Queen, Arizona.—The development of several million tons of concentrating ore in the Sacramento hill imposes on the Company the necessity of erecting a concentrator. In order to solve subordinate problems a small test mill, with a capacity of 90 tons per day, was constructed. The best results were obtained by combined hydraulic and flotation methods, flotation increasing the mechanical recovery by about 12%, and raising the total saving to 87%. In addition to this mill for determining exclusively the best methods for handling certain of the Copper Queen ore of special composition, a series of exhaustive experiments have been under way for several years in the Company's laboratories and in a plant on a working scale, having in view the recovery, by hydraulic extraction and electrolytic precipitation, of the large losses in fine slimes, wherever the Company has had to resort to concentration. The results are not yet sufficiently conclusive to act on.

Moctezuma, Sonora.—At the concentrating mill the principal addition has been a flume to carry the slimes to a large natural reservoir on the opposite side of the Nacozari river, where they will be preserved for subsequent treatment, experiments in this direction are still being conducted at Douglas. In the meanwhile some experiments on the spot have been made in the direction of economies in the mill, and others looking to radical reforms in the direction of flotation. These unfortunately have not as yet been attended with much promise.

Burro Mountain, New Mexico.—As a preliminary to the active construction of the new mill a systematic series of experiments on mechanical concentration and flotation were made to determine the methods and machinery best suited to the Burro ores. While engaged in making these tests the erection of the mill was suspended, but the experiments have proved sufficiently encouraging to justify the resumption of the construction of a mill with a capacity of 1000 tons per day. The tables of results of the experimental mill show a gradual improvement in extraction from 53.90% in May to 79.80% in December, largely through modifications in the mechanical appliances and practice.

Costs at the Porcupine-Crown Mine, Ontario

In 1914 this property, worked down to 500 ft., produced $691,324 from 40,857 tons of ore at the following cost:

COSTS PER TON MILLED.

Mining, development, etc.	$3.20	General mine expense	$1.12
Tramming and hoisting	0.39	Depreciation, taxes, office	0.76
Treatment	1.31		
Power, maintenance, heat	1.51	Total	$8.29

Alternating Current in Electrolysis

*1. When an alternating current of high frequency, about 30,000 per minute, passes through a cell consisting of two platinum electrodes dipped in any electrolyte, the electrode potentials change, thus indicating that some chemical action at the electrode surface takes place in that short amount of time.

2. When an alternating current passes through a reversible voltaic cell, there is no change in the electrode potential. If, however, one of the electrodes consists of a metal covered with its insoluble salts, the alternating current has pronounced effect on that electrode.

3. A greater amount of current could be supplied by a cell with one reversible and another irreversible electrode, when an alternating current plays in the circuit.

4. In cells like Cd–$ZnCl_2$–Hg, and Cd–$ZnCl_2$–Pt, the e.m.f. of the Hg or Pt electrode approaches the value of the zinc electrode on the passage of the alternating current.

5. In perfectly reversible electrolytic cells the alternating current has no action when impressed on the cell along with a direct current.

6. But if the electrolytic cell be irreversible, the alternating current greatly increases the current strength through the circuit.

7. This increase in current strength is due to the diminution in the back electro-motive force of polarization.

8. This diminution in the discharge potential is also observed in electrolytic cells consisting of two cathodes and two anodes, the alternating current playing between the anodes or the cathodes, but not passing through the whole circuit.

*Summary of a paper by J. C. Ghosh in Jour. Amer. Chem. Soc.

Changing Compressor Into Steam-Engine

Power has been deficient at Porcupine and Cobalt, Ontario, for some time, and several mines are working at reduced capacity. At the Hollinger, the compressor plant consists of three machines, each having a capacity of 4500 cu. ft. free air per min. They are driven direct by 11,500-volt synchronous motors. One compressor is a Fraser & Chalmers with Hoerbiger valves, and auxiliary volumetric control-valves. The other two machines are from Nordberg, compound with full Corliss valves.

To help the power situation two air-compressors and motors were converted into steam-engines and generators. This arrangement may be explained as follows: When current is impressed on the motors of the Nordberg machines they rotate and drive the machines as compressors. When steam is admitted to the cylinders, the erstwhile compressors reverse their direction of rotation, and become steam-engines driving their motors as generators. The operation is about as simple as the above description. Some adjustment of the eccentrics is necessary, in order to secure proper lap and lead of the valves for maximum steam economy. The plant has been designed for such an emergency, sufficient boiler-capacity having been installed to operate the two Nordberg machines as engines.

Under normal conditions the mine and mill are operated by hydro-electric power, but sometimes in February and March there is a shortage of water which makes recourse to steam-power necessary.

Supplies Used at the Goldfield Consolidated Mill

In 1914 this plant treated 332,750 tons of ore, consuming the following supplies:

Item.	Price per unit.	Quantity per ton, pounds.	Cost per ton.
Cyanide	$0.17105	1.87	$0.321
Zinc-dust	0.08417	0.46	0.039
Lime	0.00733	14.79	0.109
Lead acetate	0.09161	0.84	0.077

CONCENTRATES

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Silver produced by the Nipissing mine, Cobalt, Ontario, amounted to 36,585,280 oz. to the end of 1914.

Cost of stoping at Mt. Lyell, Tasmania, is $1.34 per ton. This includes all charges on ore delivered to bins at the incline hoist.

Magnetite anodes are advantageous because the magnetite is unaffected by oxygen, chlorine, or SO_4 ions in electro-chemical operations.

Mining and development at the Anaconda properties in 1914 cost $4.06 per ton treated. Transportation to the smelters cost 27c. per ton.

Malapai, a term often used in the Southwest to designate lava flows, is a corruption from the Spanish *malpais*, or bad lands, from *mal*, bad, and *pais*, country.

Erection of stamp-mills over mine-workings is undesirable. At the Simmer & Jack, on the Rand, the vibration of the 320 stamps can be felt on the hanging wall 300 ft. below the surface.

Cost of producing lead by the Bunker Hill & Sullivan company in 1914 was 1.5c. per pound at the mill and 1.91c. at the smelter, a total of 3.41c. The average price received was 3.862 cents.

In the Pearce method of tin assay the ore is fused with caustic soda or potash, in an iron or nickel crucible, and the solidified melt dissolved in water to which an excess of hydrochloric acid is afterward added.

Ore at the Copper Mountain mine of the British Columbia Copper Co., 130 miles west of Greenwood, consists of a mineralized grano-diorite that has been intruded by an intricate system of quartz-porphyry dikes.

Recovery of copper at the Washoe concentrating plant of the Anaconda company is 78%. Flotation is expected to increase the saving to 90%. Unprofitable ore in the mines will be made to yield profit thereby.

Fully 20% of the consumption of metals is met by recovery from scrap. In 1913 such secondary copper amounted to 136,500 tons and the secondary lead to 72,834 tons, in the United States.

World's production of vessels in 1914 amounted to 3153 of all kinds. These had a tonnage of 3,471,937, and horse-power of 2,986,819. The previous year's figures were 3890, 3,984,556, and 3,822,499, respectively.

Ozokerite is a mineral wax found in the vicinity of deposits of bitumen and petroleum, especially in Galicia and Utah. It is used for making shoe-blacking, artificial bees-wax, candles, ointment, insulating material, and phonograph records.

Gasoline production from natural gas in commercial quantities commenced in Pennsylvania in 1905. The output from this source in the United States in 1913 amounted to 24,060,817 gal., valued at $2,458,443. Gas totaling 9,899,441,500 cu. ft. was used in manufacture.

In the Horwood modification of the flotation process, the slime containing galena and zinc-blende is given a roast sufficient to produce a film of lead sulphate on the galena, leaving the blende unaffected, the consequence being that this blende can be floated, leaving the deadened galena behind.

Mineralogical analyses of sand should include the following investigation: igneous rocks, shale, quartz (including chert and quartzite), dolomite (including calcareous sediments), feldspar, and heavy minerals. Often the sand which passes 100-mesh, when less than 1.5% of the total, is not examined.

Panama Canal revenues from July 1, 1914, to March 1, 1915, amounted to $2,334,515. Operation and maintenance cost $2,595,613. The loss on operation was $261,098. These figures need the following explanation: Operation and maintenance proper are summarized under the following heads: admeasurement of vessels, local inspection, aids to navigation, pilotage, damage to vessels, maintenance of transportation tracks, Gatun locks,

Gatun spillway, Gatun dam, Pedro Miguel lock, Pedro Miguel dam, Miraflores locks, Miraflores east dam and spillway, Miraflores west dam, dredging, and maintenance of Gatun lake, Gatun-Mindi levee, and Naos Island breakwater. The total cost of the work in Culebra cut (now Gaillard cut), attributed to operation and maintenance, is $1,012,695. This includes the work north of Gold Hill, where the channel was once opened, but not the work at Cucaracha slide, which has been considered construction work, as the channel was not clear on July 1, 1914.

EXTRACTION of gold and silver at the Belmont mill, Tonopah, in 1914-1915 was 95.78 and 91.81%, respectively. The total was 92.99%, or 1.46% lower than in 1913. Several conditions were responsible for this. Chief among these was the more refractory nature of the ore. It contained considerably more sulphides of the base metals. As illustrating this with the 1914 ores, averaging 0.2336 oz. gold and 22.3 oz. silver, and with no change in concentrating methods or appliances, about 52.5% more concentrate (by weight) was made than in 1913. The ores then averaged 0.2675 oz. gold and 26.331 oz. silver, according to the mill superintendent, A. H. Jones. The table herewith shows the comparative concentrating results of the two years, and the increase in the refractory content of concentrate made:

	1913.	1914.
Average gold content of ore milled, ounces	0.2675	0.2236
Average silver content of ore milled, ounces	26.331	22.3
Concentrate, tons	794	1211
Percentage by weight	0.463	0.668
Gold per ton, ounces	3.167	2.368
Silver per ton, ounces	611.08	446.05
Iron, per cent	27.0	28.5
Sulphur, per cent	24.4	28.3
Copper, per cent	0.39	0.30
Lead, per cent	1.16	0.9
Zinc	0.8	0.6

In this connection it will be noticed that in 1913 the ratio, by weight, of silver to gold was 101.6:1, while in 1914 it was 95.4:1. In Belmont ores, at least (and aside from the high-grade ores), an increased proportion of gold seems to be indicated with the lower grade and more base ores.

THE FORMATION and distribution of residual iron ores is summarized as follows by C. L. Dake, in a paper to be presented to the September meeting of the A. I. M. E. in San Francisco: (1) Residual soils rich in iron are produced both by weathering and by hydrothermal alteration. (2) Weathering produces important accumulations of iron sediments only from limestones and basic igneous rocks. In other rocks, such concentration is of minor importance. (3) Only temperate and tropical regions of moderate to heavy rainfall yield residual weathering products in abundance. Polar and arid regions are more favorable to mechanical disintegration. (4) Laterites, which by reason of their lower silica content and the nature of the parent rock are richer in iron than ordinary residual clays, are developed only from basic igneous rocks, in tropical regions of heavy rainfall. Such laterites are widespread in the tropics, and represent enormous concentration of residual iron. (5) Hydrothermal decay has, in the Hawaiian islands, produced iron-rich residual soils comparable to laterites. Observation is limited. Little is known of the distribution or importance of this type of residual deposits. (6) Of the above types, hydrothermal decay, normal weathering, and lateritic weathering, the latter is probably of the greatest importance. This is due both to the great abundance and to the higher iron content of the laterites.

IN SUMMARIZING their investigations into the electric smelting of copper ores, Dorsey A. Lyon and Robert M. Keeney, in *Bulletin* 81 of the U. S. Bureau of Mines, conclude that the process is nothing more than the substitution of electric heat for the heat derived from the combustion of carbon. Inasmuch as the carbon which is used either in the reverberatory-furnace or in the blast-furnace plays no important part in the reactions that take place in these furnaces, there is no reason metallurgically why electric heat may not be substituted for the heat derived from the combustion of carbon. In fact, as the authors have attempted to point out, in some cases the reactions would take place to better advantage in the neutral atmosphere of the electric furnace than in the reducing or partly reducing atmosphere of the combustion furnace. Therefore, the practicability of using the electric furnace for the smelting of copper ores would largely depend on the relative cost of coke and electric power. As the use of the electric furnace is not advocated as a competitor of the combustion furnace, but as a substitute for it, in those localities where it is not advisable, because of the high cost of fuel, to use the combustion furnace, there is no apparent reason why the electric furnace may not be developed as a substitute for the combustion furnace where the conditions are such as to warrant its use, especially in the treatment of copper-bearing ores. In this connection it is to be remembered that the development of the electric furnace in the iron industry for the reduction of iron from its ores was due to necessity. As a matter of fact the field for the electric furnace in the reduction of iron from its ores is a limited one. Perhaps the same is true as regards the possible application of the electric furnace to the treatment of copper ores; but, judging from the comparative costs, which would be about equal, it would seem that the possibilities of the electric furnace for the treatment of copper ores are greater than those for the treatment of iron ores, because there is not so great a difference between the cost of coke and of electric power in copper-mining districts as there is in iron-smelting centres. Also the cost of electric power is constantly becoming less, through improvements in gas engines and steam turbines, so that in districts where water-power is not plentiful but cheap fuels unsuited to coke making are available, it may be found more advantageous to use electric heat than the heat derived from the combustion of coke.

Missouri Minerals at the Exposition

When the mineral production of Missouri is mentioned, one naturally thinks of lead and zinc. This state leads all others in the output of these metals. In 1914, out of 534,982 tons of lead from domestic ore, 194,275 tons was supplied by Missouri. In the case of spelter the contribution was 114,019 tons out of 343,418 tons for last year. In 1913 the total value of minerals in Missouri was $54,001,088. Of this, lead was $15,498,208; zinc, $13,995,856; coal, $7,468,308; clay products, $6,602,076; cement, $4,556,822; and stone, $2,538,699.

In the Palace of Mines and Metallurgy at the Exposition, minerals produced in Missouri are well displayed. A fitting facade to the booth is one which at one side is represented a lead-mine face, at the other a zinc-mine face, a railing of pigs of lead and spelter, a cornice of finished spelter above all, and a main entrance of dressed limestone from the Carthage quarries.

On entering the booth the first exhibit is a model of the well-known Oronogo Circle zinc-lead mine near Joplin. The scale is 1 in. to 15 ft. It was constructed by Messrs. Ruhl and Shanklin. Otto Ruhl is in charge of the mineral booth. The model represents 22 acres. Two levels are shown, 160 and 230 ft. The former has a 60-ft. face. Ore in pillars is worth $1,000,000. Ore is carried from drift-headings and stopes to shaft bottoms by endless rope-haulage. From the shafts gasoline motor trains haul the ore to the 1000-ton mill. An average of 4% zinc ore is treated in this plant. It is planned to work the property by steam-shovels. From 15 to 45 ft. of overburden will have to be moved. About $1 per ton covers mining and milling charges. This is about the average cost for the southwest zinc region.

A case of 60 to 64% ores contains highly interesting specimens. These are sphalerite from the Baltimore mine, Coahuilla at Duenweg, Oronogo Circle at Oronogo, Waneta Pearl at Joplin, Otis at Joplin, and Napoleon at Joplin. Ruhl and Shanklin exhibit pseudomorph sphalerite after calcite crystals.

Another case contains calcites and dolomites. The former show twining. There are also rice-grained dolomites and breccias. 'Mineral eggs' or nodules of chert are found in limestone in small groups, sometimes in ore. Several samples of these are shown. A fine collection of calcite crystals is in the same case. From mine La Motte, in the southeast, is on view a complex sulphide ore containing nickel, cobalt, lead, and copper. This is a noted mine. Glass tubes containing borings from drill-holes at Belleville, Neck City, Wentworth, Chitwood, Prosperity, and Duenweg are of interest.

Mineralogists will find much to study in the case of sphalerite coated with crystals of chalcopyrite, barite, calcite, silica (rare), marcasite, cadmium, chalcopyrite and barite, and casts of marcasite showing leaching. Calamine, silicate of zinc, is a regular product of the district. Specimens of this ore are shown, including large slabs from the Granby property, pseudomorphs (zinc carbonate after calcite), ore in transition from sphalerite to the oxide form, and calamine coated with zinc carbonate.

The next case shows the deposition of ores in the zinc region. Included are the following: zinc ore from the 'free-ore' or 'soft-ground,' 'spar ground,' 'disseminated,' 'shale,' 'watercourse,' and 'sheet-ground' types of deposits. The last named yields 60% of the ore from the districts. Calamine from the disseminated deposits of Duenweg is hard and is troublesome in the mills.

The large double terminated scaleno-hedron calcite crystals, amythist colored calcite crystals, and calcite crystals with barite crystals on their surfaces are of great interest.

A large number of photographs illustrate the character of all stages of development and production of the southwestern Missouri region, such as prospecting by horse, Keystone, and churn-drills, hoisting by windlass, whim, and steam plants, underground work with timbering, pillars, drifts, and ore transport, power-plants, crushing, concentration, and large heaps of concentrate. One picture is of interest. It shows the only shipment of ore to Europe. This came from the Joe Louis mine at Webb City in 1898. The State Geological Survey exhibits drill records of deep wells in the state. The deepest is down to 2700 feet.

Ore treatment in the zinc district is simple. This is well shown by a working model of a Joplin mill. It has a capacity of 25 tons in 8 hours. The process is as follows: Ore is broken in a Carterville crusher, and further reduced by slow-speed rolls. The product is elevated to a ⅜-in. trommel, undersize to rougher jig, oversize to return rolls to be crushed and sized again. The rougher jig has four 14 by 22-in. cells and a dewatering box. Concentrate from the jig goes to an elevator, which feeds a cleaner jig. The latter jig consists of five 12 by 20-in. cells and a dewatering box. Tailing is dewatered, screened, and the fines further concentrated. Tailing or 'chats' from the zinc mills are used for many purposes. When mixed with cement a fine artificial stone is produced. The Joplin railway station and a large department store are among the many buildings made from this material. Such a plant uses about 30 hp. Treatment charges are from 10 to 25c. per ton.

Concentrate is shipped to the Matthiessen & Hegeler Zinc, Grasselli Chemical, Edgar Zinc, American Zinc Lead & Smelting, Illinois Zinc, Granby Mining & Smelting, and Hegeler Bros. companies smelters in Oklahoma, Illinois, and Kansas. Most of the concentrate goes to Illinois plants. Most of the smelters mentioned were described in the *Press* during 1914. Each firm exhibits slabs of zinc. A stand holds pig zinc, rolled plates, and rolled sheets. A case contains the following zinc products; nails for roofs, greenhouse points, shoe nails, plate-glass points, fruit-jar lids, wet and dry-cell batteries, and washboards for domestic purposes. Ore treated in the southwest in 1914 amounted to 6,774,000 tons.

The exhibit of lead ores and products is also a valuable one. The largest ore deposits are in the southeast at Flat River. They are known as the disseminated type. A pyramid of ore weighing two tons is displayed by the Federal Lead, Doe Run Lead, St. Louis Smelting & Refining, and Des Loges companies. Lead ore also occurs in the southwest in limestone, spar, disseminated, and sheet ground. Galena crystals shown are highly interesting. One case contains large ones with smaller ones on their faces. Another has crystals from the American Davey mine, Webb City. Galena with blende from F. C. Wallower mine, galena coated marcasite from the Sitting Bull; interwined crystals from Flynn & Co., Central City, galena coated with carbonate from the Delta, Spring City; and partly leached crystals, the marcasite gone showing the action of acid waters.

Missouri galena is considered the best for wireless telegraphy. Ore treated in the southeast in 1914 amounted to 4,718,300 tons.

The Picher Lead Co. exhibits four tons of 99.99% lead in pigs, also sublimed lead products of various colors for paint and glass manufacture.

Other mineral exhibits are as follows: Coal, sections of 42 to 60-in. veins, reserves in Missouri are estimated at 79,000,000,000 tons; clay products such as building and sewer tile, glazed and unglazed brick, fireclay for furnaces and chemical works, firebrick and terra-cotta (a large U. S. flag is made of this colored material); iron ore, pig iron, and products; tripoli; and barytes. The last is interesting from the fact that it is mined by farmers.

The total tonnage of lead, zinc, and copper ores mined in Missouri in 1914 was 11,492,300. With a few exceptions, the zinc ore is produced by small syndicates and companies; on the other hand, lead ore is mined by large well-known companies. The difference is most striking.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

CRIPPLE CREEK, COLORADO

Mill Competition.—Blue Bird Mine.—'Split-Check' System. Lessees on Ingham Vein.—District Outlook.

As predicted in my letter of May 15, a merry war is about to begin among operators of mills, ancient and modern, which treat Cripple Creek ores. The most recent news comes in the form of a circular to the bondholders of the United States Reduction & Refining Co. It is as follows:

"The newspapers have announced the formation of a so-called protective committee for the bondholders of the U. S. R. & R. Co., and it is therefore to be assumed that you will shortly receive the customary notice from this committee requesting you to deposit your bonds. The present management of the Reduction company is of the opinion that you should, for the present, be very cautious before identifying your interests with the committee. At the last annual meeting of the stockholders, held April 23, 1915, an entirely new management was elected as a consequence of proxies solicited by Byrne and McDonnell. The gentlemen who controlled the old management, in anticipation of failure to re-elect their candidates, caused a receiver to be appointed for the company the day before the meeting, at the instance of the trustee for the bondholders. The bondholders' committee just announced is formed in sympathy with the same bondholders who secured the appointment of a receiver when it became apparent that they were about to lose control of the company through action of the stockholders. The newly elected president of the Reduction company, Robert E. McDonnell, is now in Colorado with his counsel investigating the local situation. It appears from the papers in the receivership suit that the property of the Reduction company has been rendered of little value by reason of the acts of the old management whereby the Reduction company agreed with a competing company not to engage in the business, and thereby permitted the competing company to secure for itself the business of the Reduction company. It is the intention of the newly elected officers of the Reduction company to thoroughly investigate the affairs of the company, with particular reference to the relations of the gentlemen in control of the Reduction company with this competing company. For the present we desire to suggest to the bondholders that they should not give their adherence to any committee until the investigation now being conducted by the new management is concluded and its results announced." This is signed by the secretary, R. Mason Kirkland.

Mr. McDonnell, the new president, was a visitor to Cripple Creek on May 8 and 9.

The Franklin Leasing Co., operating the Blue Bird mine on Bull hill, is greatly elated over a recent discovery which was opened simultaneously on the No. 17, 19, and 21 levels. From the centre of the vein, selected samples have assayed as high as $50 per pound. The vein matter as mined will average about 3 oz. per ton. The company secured its lease on the mine some three months ago. It began shipping almost at once, subletting various blocks in the mine on the 'split-check' basis. This is the local term applied to the system wherein the company provides all supplies and the lessee furnishes the labor only, the company and the lessee then dividing equally the net proceeds from the ore sold. The only feature against the present development is the previous history of the mine. It always was a spotted or pockety mine. It is to be hoped that the new shoot will develop into a persistent vein.

Probably the most profitable lease in the district is that of Starkweather and Wilson, on the Ingham vein of the Doctor Jackpot Mining Co.'s property. It has been returning a net profit of $25,000 per month to the partners. This ore was exposed in the old Anaconda-Raven adit. It had been unnoticed for years, and was opened recently by accident.

In general, the district is fairly quiet. Steady work is the slogan on all sides. The ill effects of the boom at the beginning of the year, influx of men for whom there was no work, and of speculators of various kinds, due to the Cresson development, have been safely passed, and the district resumes the even tenor of its way. Such discoveries as that of the Cresson are wonderful, and highly pleasing to the owners; but the average laborer fails to understand that they do not result in employing a single man more in the particular mine. Seldom do they result in new work being started. We doubt if six more machines are drilling today than there were six months ago, before the famous vug was opened. One amusing thing about the rich ore, however, is the amount of freak advertising that it has given rise to. The local sampling company, which feverishly bought the initial shipment, being stung considerably by the operation, now seeks to draw business its way by issuing facsimiles of the check which it gave in payment, claiming it to be "the most valuable single shipment ever made." Most technical men will recall the shipment from the Mohawk at Goldfield, Nevada, to the Selby smelter in February 1907. It still leads as "the most valuable single shipment," as the following comparison will show:

	Net tons.	Gross value.	Net returns.
Mohawk	48	$591,637	$574,958
Cresson	150	.....	468,637

Of course, to boost your home town, or district, is natural, but this district has had all the boosting it needs, and what it wants now is development along safe and conservative lines.

TORONTO, ONTARIO

Iron and Steel.—Fond du Lac Silver District.—Porcupine Gold Output. Hollinger. McIntyre. Rea. Dome Lake. South Thompson.

The depression that has so long prevailed in the iron and steel industry is giving place to activity, owing to large orders received for munitions of war. The total value represented by these contracts to Canadian firms, according to a statement by the Minister of Militia, amounts approximately to $175,000,000. Plants are working day and night. The value of the daily output is about $500,000. Hitherto this industry has been confined to the Eastern provinces, but the Western manufacturers are now coming in for a share of this profitable business. Contracts for shrapnel are being let to plants at several industrial centres west of Winnipeg. The increased demand for steel has greatly stimulated the iron-mining industry. The Dominion Steel Corporation and the Nova Scotia Steel & Coal Co. have between them about 700 men employed in their iron-ore mines at Wabana, Newfoundland. These forces will be largely increased this month. The mines are to be operated to capacity. In addition to the orders for shells, there is heavy demand for toluol, a by-product of steel manufacture used in making explosives, for which orders to the amount of from $2,000,000 to $3,000,000 have been received. The manufacture has been

already commenced by the Dominion Steel Corporation. A plant is being installed for that purpose in connection with the Algoma Steel Works at Sault Ste Marie.——Business in the ordinary lines is also showing some improvement. The Dominion and Algoma corporations have each received contracts from South Africa for 35,000 tons of steel rails, at a reported price of $29.20 per ton f.o.b.

Glowing reports continue to be published as to the richness of the new silver-mining district at Fond du Lac, at the northeast corner of Lake Athabasca, in Saskatchewan. Numbers of prospectors have gone out there. Sufficient importance has been attached to the accounts of extraordinarily rich finds, corroborated to some extent by samples shown by returning prospectors, to induce the Geological Survey to take action. An authoritative statement as to the value of the field will shortly be available. A party in charge of Charles Camsell will make an examination of the district.

Now that the difficulty arising from power shortage has been, temporarily at least, overcome, production at Porcupine is normal. May 1 was a record day for bullion shipments. The total value amounted to $154,661. The Hollinger contributed $48,000; Dome Mines, $64,500; Porcupine Crown, $30,961; and McIntyre, $11,200.——The Hollinger has 120 stamps dropping. The McIntyre is improving. No. 4 vein on the 600-ft. level is showing a width of 26 ft., assaying $12 per ton. Other levels are also looking better. Some important changes have been made in the directorate. Alexander M. Hay, of Toronto, has been elected president, and Sir Henry M. Pellatt, a prominent Canadian financier, is one of the new directors.——The Rea mine, which has been temporarily closed down, is being financially re-organized, and is taken over by the New Ray company. Diamond-drilling, which has been carried on for some weeks, is reported to have been successful in finding additional orebodies. It will be continued.——The Dome Lake has also been closed down pending financial re-arrangements.——The South Thompson property has been taken over by the Krist-Porcupine, which will now be known as the Krist-Thompson Co.——The Gold Reef has been unwatered. It will be operated with new equipment.

VICTORIA, BRITISH COLUMBIA

MINING SITUATION.—PLACERS, GOLD, COPPER, SILVER-LEAD, ZINC ORES.—FRENCH PROCESS.—COAL *v.* OIL.—ROCHER DÉBOULÉ MINE.—HAZELTON DISTRICT.

Generally mining in British Columbia is not now affected to any considerable extent by the War. Those properties that last year experienced a decided set-back have in a large measure resumed work, or, where production is not normal, other influences now being mainly responsible for lack of progress.

For instance, placer gold mining was continued as usual throughout the whole of the 1914 season. Now that the opening of the current season is at hand, all the larger placer mines that were operating last year are being prepared for this year's hydraulicking or other systems.

In lode gold mining, the chief important mines on the list of producers at this time last year, but not now contributing to the production of this metal, are those of the British Columbia Copper Co., the continued suspension of which is attributable to other causes.

Several lead and silver-lead mines, notably the Bluebell, in Ainsworth division, and the Standard, in Slocan, have not yet resumed production, owing mainly to less favorable terms now obtainable from the smelting company. The last named, if not both the latter, will most likely shortly be again on the shipping list. Zinc-lead ore is being treated at the concentrator of the Silverton Mines, Ltd. It owns the Hewitt-Lorna Doone claims, situated a few miles from Slocan lake. The Rambler-Cariboo and Ivanhoe mills, in Central Slocan, are also turning out a silver-zinc as well as a silver-lead product. Both the Ruth and the Slocan Star concentrating plants, in the same neighborhood, are being prepared for early resumption of milling. Both are equipped for making the two products mentioned. Further, the Standard mill, at Silverton, is having added to its present modern equipment for concentration of silver-lead-zinc ores a small experimental unit, with the object of giving a trial to French's process for separation of zinc and lead. This process, as stated in an official description published in the Annual Report of the Minister of Mines for British Columbia for 1911 "aims at the extraction and recovery of the zinc contained in ores, such as the silver-lead-zinc ores of the Slocan, leaving as a residue the silver-lead, iron, and gangue-matter, which would afterward be smelted in the same manner as a lead-ore free from zinc."

The Granby Consolidated company is now operating its mines and smelting works in the Boundary district to normal capacity, thereby again contributing largely to the production of copper and, in much smaller measure, to that of lode-gold and silver.

In the Kootenay district, the Consolidated company has not yet resumed production of silver-copper ore at its Silver King group, near Nelson.

MAP OF BRITISH COLUMBIA.

On the Coast, production temporarily has been stopped at the Britannia mine as a result of the destruction, on March 22, of its aerial tramway upper terminal and other works at the mine. Preparations for resuming ore production are being energetically carried on. The Granby Consolidated Co.'s comparatively large addition to the output of copper in the Coast district, is however, more than compensating for the present loss in total quantity caused by the enforced suspension of production from the Britannia mine.

As to coal mining, the position is not generally satisfactory. To a considerable extent this is attributable to the substitution of oil for coal as fuel by railway and steamship companies. With the object of reducing the advantages fuel oil has in competition with coal in the Coast and lower mainland districts, the Dominion Government is being urged to place a sufficiently high custom duty on fuel oil as will in large measure protect the coal-mining industry. On the other hand, transportation companies are also making strong representations to the Government, showing that their considerable expenditures in making provisions for the use of oil as fuel must also be taken into serious account.

Another mine has been added to the list of copper producers in the Coast district of British Columbia, namely, the Rocher Déboulé mine. It recently made its first large shipment, consisting of about 450 tons of ore, consigned to the Granby Consolidated company's smelting works at Anyox, Observatory inlet. This property is described at some length by John D. Galloway, assistant mineralogist, in *Bulletin* No. 4, Omineca Mining Division, issued a few weeks ago by the Provincial Department of Mines. It is situated in Juniper basin, at the head of Juniper creek, and is distant 10 miles from Skeena Crossing, a flag station on the Grand Trunk Pacific railway, 10 miles west from New Hazelton. The property comprises six mineral claims on Rocher Déboulé mountain. It is owned by the Rocher Déboulé Mining Co. There are three main veins, in grano-diorite; the highest vein contains copper-iron minerals, the middle and lowest veins galena and zinc. In August 1913 the mine was leased to the Montana Continental Development Co., a Butte, Montana, organization. Under the terms of the lease, this company agreed to equip the mine with machinery, construct aerial and surface tramways necessary for the transport of ore to the railway, and develop the top vein by a cross-cut adit, in return for the right to extract as much ore as possible during a two years' tenure of lease. The lessee company put in on Juniper creek, about five miles above Skeena Crossing, a small hydro-electric power-plant, and constructed a transmission line thence to the mine; installed a 6-drill Canadian Rand compressor; drove a cross-cut adit about 500 ft. to the vein; constructed a surface tramway to the upper terminal of the aerial tramway near the summit of a ridge overlooking Skeena river; and built the aerial tramway, in two sections, nearly four miles down to orebins on a spur from the railway at Carnaby; erected mine buildings; and put in a portable saw-mill driven by a 20-hp. electric motor. The main vein is described as varying from 2 to 12 ft. in width, and includes a fairly regular shoot of from 1 to 4 ft. of ore, samples of which taken by Mr. Galloway ranged up to 1.20 oz. gold and 1.80 oz. silver per ton, and from 9 to 13.8% copper. Other properties on Rocher Déboulé mountain being worked are the Red Rose and the Great Ohio group.

Several silver-lead properties in the neighborhood of Hazelton are preparing to ship ore.——The Silver Standard group, on Glen mountain, four miles east of Old Hazelton, last year shipped to Trail 736 tons of ore that contained approximately 200 oz. of gold, 122,000 oz. of silver, and 282,000 lb. of lead. Production was discontinued when the metal markets were disorganized by the War. Now that the ore can be disposed of, it is intended to resume shipping to the smelter.——The American Boy is on Nine-mile mountain, eight miles from New Hazelton. Last year 48 tons of ore was sent to Trail to determine the value in bulk. There occurs in the group of eight claims a series of parallel veins, in four of which development has been done. Mr. Galloway states that the American Boy, like the Silver Standard, has a considerable quantity of ore that could be handled at a profit if concentrated before shipment. Freight and treatment charges were last season about $23 per ton, exclusive of the cost of hauling down the hill to the railway at New Hazelton, so that under the conditions only high-grade ore could be shipped at a profit. Average assay returns from ore on the main dump from the shaft on No. 3 vein show a value of more than $20 per ton. Such ore may not at present be shipped crude. It should, however, be possible to effect a simple water concentration that would result in a product running from $150 to $200 per ton.——Another prospective shipper is the Silver Cup group of four claims, also situated on Nine-mile mountain, under lease to George and Roy Clothier. Last season they opened a body of good ore. They have already commenced this season's work. Several veins have been found; half a dozen drifts have been run on the main vein at different elevations. A test shipment of 23 tons of selected ore contained about 140 oz. of silver per ton.

FAIRBANKS, ALASKA

Tolovana, Trails, and Prospects.—New Custom Mill at Fairbanks.—Quartz Mines.—Antimony Producer.

By far the most interesting topic at present, April 9, is the new Tolovana district, in which at least two creeks with fair sized pay-streaks have been located. It is 60 miles by winter trail to Livengood creek, the discovery-creek, from Olnes, a station on the Tanana Valley railroad. The best 'pay' so far has been located on Olive creek, a tributary of the Tolovana river. Various estimates place the grade of the ground up to $5 per square foot of bedrock, which is high grade. So far the width of the streak is slightly over 200 ft., although the face of the cross-cut is still in good pay. On Livengood creek, fair pay has been cross-cut for 75 ft., but it is not as rich as that on Olive creek. All the ground is rather shallow, from 20 to 40 ft. deep where the pay has been found. It is easy to work. The winter trail will not last for over a week longer, in fact, most of the trail is bare at present. Only small plants can be taken in that way, 10 hp. being about the limit, there being seven divides between the railroad and Livengood creek. Summer travel will go in on the Tolovana river, as gasoline boats with good-sized scows can make the mouth of Livengood creek after several log-jams are cleared out. These are quite extensive, however, of many years' accumulation, consisting of large timber. As most of the larger jams are on horse-shoe bends, there is a project on foot to open a new channel across the bends by dynamite just before the break-up, the spring freshet being able to clear out a good channel if given a start. It is also possible to get freight in by Mike Hess creek, direct from the Yukon river, there being a water route to the head of Livengood with only a slight divide to freight over. The first deal of any importance in the new area was the purchase of all Jay Livengood's interests by Dave Caseaden for about $40,000. This purchase covers the pay on Olive creek so far as opened. Many men are going in to the new diggings this summer, and many old-timers outside have been wired to get in as soon as possible.

In the Fairbanks district the completion of the Helig custom mill is the latest event of interest. This enables for the first time the many good claims on Fairbanks creek to have ore milled cheaply. One custom mill had been erected previously at the head of the creek, but did not prove a success. It was scrapped. The new mill will treat about 25 tons per day, according to the first runs. It is of substantial construction throughout. Plenty of water is available. Being situated within a few hundred yards of some of the best mines, it should prove a boon to the creek prospectors. The crusher is a Huntington mill. It is well suited to the free-milling ores of the district. A gyratory crusher made by the Straub Mill Co. supplies fine feed to the mill. Mines that have ore ready to be hauled to the mill include the American Eagle, on which Foss & Farvean are the lessees; L. J. McCarty; Stevens, Boyd & Kleinsmidt; Heaton & Bogberg; August Hess; Huddleston & McNeil; Marino, Brankovits & Co.; and others. Over 1000 tons is ready to haul. The reserves in some of the properties are difficult to estimate.

It is reported that Sy Scrafford, who holds an option on the Chatham Mining Co.'s holdings, has a 4000-ton contract with San Francisco people for antimony ore. A large body of 7% ore, free from the other minerals, was cut in the main adit two years ago. This is being developed. The run-of-mine ore is put through the crusher and hand sorted. It is said that there is 200 tons or over ready to ship. Mr. Scrafford also has a crew working on an antimony prospect on Treasure creek. On the surface this shows chances for a large body of good ore, but the extent is not known. The transportation company has given a $9 rate from Fairbanks to San Francisco.

Details of the quartz mine operations will be published in another issue of this journal.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Cordova

On May 4 a total of 1950 tons of copper ore was awaiting shipment to Tacoma on the wharf at Cordova. Fifty tons was from the Mother Lode mine, the remainder from the Bonanza and Jumbo. The ore averaged 67% metal. The total value of the ore was about $500,000.

Fairbanks

It is estimated by the First National Bank that the spring clean-up for the Fairbanks district will be $355,000.

ARIZONA

Gila County

The combined reports of the Old Dominion Copper Mining & Smelting Co., United Globe Mines, and Old Dominion Co. for 1914 have been issued. The last named controls the other two operating companies at Globe. It received $860,410 in dividends from these companies. Including increase in value of Old Dominion Copper shares, the income was $1,415,009. Out of this $1,173,412 was distributed in five dividends totaling $4 per share. The year commenced with a surplus of $191,468, and ended with $433,065. Dividends to date total $5,853,713.

Mining operations at the United Globe property were confined to prospecting, development, and ore extaction on the Old Dominion, Maggie, Josh Billings, Buffalo, and Grey veins. Development totaled 13,864 ft. A total of 155,205 tons of mixed ores was extracted and shipped, averaging 3.57% copper. Of this, 121,812 tons was concentrating ore. The yield in 1913 was 167,920 tons of mixed ores. The ore last year contained 11,086,674 lb. copper, 91,582 oz. silver, and 1580 oz. gold.

Revenue from metals, etc., was $1,095,561. The profit was $432,538. Dividends amounted to $425,500. The year started with a balance of $372,739 and ended with $238,520. Dividends to date amount to $1,955,000.

The Old Dominion Copper company's report states that development totaled 17,783 ft. Some of this work was expensive and unpleasant. The flow of water varied between 3,350,000 and 5,625,000 gal. per 24 hours. The average was 3,754,542 gal. Of the 1,349,210,000 gal. pumped, 729,580,000 gal. was sold to the Miami company. Of the considerable amount of work done, motor haulage was started on No. 12 and other levels. On the former it is 7000 ft. long. The west end orebodies supplied most of the ore. High-grade oxide ore was mined here and sent direct to the smelter. The centre part of the mine produced most of the concentrating ore. Ore extracted totaled 129,813 tons, averaging 7.44% copper. Cost of mining was $5.20 per ton, an increase due to troubles mentioned. The new mill started at the end of October. Flotation has considerably increased extraction. The two plants concentrated 151,893 tons at a cost of 93.2c. per ton. The furnaces reduced 207,595 tons of charge, costing $2.669 per ton of new charge smelted. Including custom ores the yield was 30,210,361 lb. copper, 148,459 oz. silver, and 3309 oz. gold. From the company's output on 17,816,284 lb., 33,311 oz., and 603 oz. respectively, the revenue was $2,473,582. Other revenue made $2,674,206. Net earnings were $978,510. Dividends amounted to $445,500. The year started with a surplus of $1,193,247, and finished with $967,293. Depreciation amounted to $752,878.

Globe men have taken a six-year lease of the Amster copper claims. They are known as the Virgin Lady and adjoin the Old Dominion Keystone on the east.

Pima County

Articles of incorporation for the Tucson, Cornelia & Gila railroad were filed last week at Phoenix. The authorized capital is $3,600,000. Directors are C. A. Briggs, L. D. Ricketts, J. C. Greenway, G. R. Campbell, C. L. Knapp, Joe Curry, T. M. Schumacher, H. J. Simmons, and Walter Douglas. Work will begin as soon as possible. One-half of the survey is already finished. The first construction will probably be from the junction with the Southern Pacific at Gila Bend to Cornelia, a distance of 45 miles, but this has not been fully decided.

ARKANSAS

The value of the mine output of lead and zinc in Arkansas for the year 1914 was $65,214, against $55,120 in 1913.

CALIFORNIA

In *Bulletin* 594 of the U. S. Geological Survey, James M. Hill discusses some mining districts in northeastern California and northwestern Nevada. With maps, illustrations, and index, the work covers 200 pages. There were three districts in California examined, and sixteen in Nevada in 1913, in Lassen and Modoc, and Mineral, Douglas, Washoe, and Lander counties respectively. As will be seen by the map, these places are widely scattered. In the region covered, sedimentary rocks ranging in age from Paleozoic to Mesozoic were noted. In nearly each district they have been intruded by granitoid rocks, of a generally remarkably constant mineralogic composition. Lava flows cover a considerable part, particularly along the western border of Nevada, and northeast California. In a few places are accumulations of partly consolidated gravels, especially in northwest Mineral county and along

REGION DESCRIBED IN REPORT. NUMBERS REFER TO TYPES OF ORE DEPOSITS SUMMARIZED.

Truckee river near Reno. In a tabulated summary of the ore deposits of the area described in the report, the following show the chief characteristics:

Hayden Hill, Lassen county, gold in fine-grained porcelain-like white quartz-adularia veins, and open brecciated veins. Winters, Modoc county, gold in calcite and quartz adularia (silicate of aluminum and potassium) veins. High Grade, Modoc county, gold in brecciated country rock cemented by quartz and adularia, pyrite in glassy rhyolite. Gardnerville, Douglas county, gold and pyrite, and copper in quartz veinlets and in replacements in crushed altered andesite. Red Cañon, Douglas county, silver-lead, copper, and gold-silver in veins in sediments, contact-metamorphic deposits, and veins in quartz-monzonite. Wellington, Douglas county, gold-silver in veins in quartz-monzonite. Battle Mountain, Lander county, silver-lead, antimony, and gold-silver in veins in sediments, copper in contact-metamorphic deposits; gold in veins in andesite, also local placers. Skookum, Lander county, silver-lead in veins in dark silicious shales. Rees River, Lander county, silver-lead in veins in shales and quartzite, and in quartz-monzonite. Washington, Lander county, silver-lead and antimony in veins in shales; gold and copper in replacements in silicified limestone. Kingston, Lander county, silver-lead and gold-silver in veins in sediments and in quartz-monzonite. Granite, Mineral county, copper in veins in grano-diorite. Pine Grove, Mineral county, gold-silver in veins cutting into andesite. Aurora, Mineral county, gold-silver in fine-grained porcelain-like white quartz veins. Hawthorne, Mineral county, silver-lead and gold-silver in veins in sediments and intrusive; copper in contact-metamorphic deposits. Santa Fe, Mineral county, copper in contact-metamorphic and associated replacements in limestone; silver-lead in veins in sediments; gold-silver in veins in quartz-monzonite. Silver Star, Mineral county, gold-silver in fine-grained white quartz veins in sediments; gold-silver and silver-lead in quartz veins in sediments. Cottonwood, Washoe county, silver-lead and gold in veins in slate, quartz-monzonite, and volcanic rocks (these are not definite); Peavine, Washoe county, copper and gold-silver in veins in sediments and intrusives; gold-silver in veins in andesite.

Metal production of the districts is as follows: Hayden Hill, $1,684,774; Winters, about $1000 to $1500 per month during the past two years; Gardnerville and Red Canyon, $29,165; Battle Mountain, $276,843; Reese River, approximately $50,000,000 (in 1911 it was $77,199); Pine Grove, $163,741; Aurora, estimated at $27,000,000; Santa Fe, $163,570; Silver Star, over $400,000; and Peavine, about $25,000.

This report is interesting. Individual properties and the possibilities of the areas are discussed.

Amador County

The Plymouth Consolidated reports as follows for April: ore treated, 10,550 tons; gold yield, $55,860; operating expenses, $21,855; development, $9392; and surplus, $24,613.

Calaveras County

On No. 4, 5, and 7 levels of the Calaveras copper mine the faces average 3%. Streaks assay 15%. The sorting belt is working well. A flotation process will be in operation in a few days. Prospects generally are considered bright.

Inyo County

The 10-stamp mill at the Casa Diablo is nearly complete. A Fairbanks-Morse gasoline engine will drive the plant. The mine is expected to produce $40 ore.——The Bishop Creek mill was started on May 20. Some good ore has been opened on No. 2 level.

Nevada County

Fifteen inches of $107 ore has been cut in a rise from 800 to 665 ft. in the Union Hill mine. Generally development is encouraging.

Placer County

In *The Placer Herald* for May 15, T. F. Haney describes the Last Chance mining district. Owners and lessees are doing a fair amount of work in the Pacific Slab, Rublin, El Dorado, Home Ticket, Brooklyn and Olympia, Belle Verne, Dixie Queen, Pinenut, Blue Eyes, Big Bar, Haney Consolidated, Glenn, and Harmeson and McKinley. Some of these are gravel mines.

Shasta County

(Special Correspondence.)—San Francisco people are negotiating for the Greenhorn copper property, near Tower House. An examination is being made. A small amount of work has exposed high-grade copper ore. Some assaying 13% has been extracted. Operations will be in charge of M. E. Dittmar.

The Mammoth Copper Co. is actively developing the Spread Eagle and Friday-Lowden copper claims, which were acquired last year. The new ore-separating plant near the Mammoth mine is in operation, and large quantities of high-grade zinc ore are being shipped to Oklahoma smelters. It is reported that a fourth furnace will be blown in at the Kennett smelter at an early date. This leaves No. 5 in reserve. The bag-house has been enlarged sufficiently to handle fume from four fur-

The Field Process Co. is preparing to enlarge its plant at Redding. Chambers for chemical treatment of SO_2 gases escaping the refrigerating apparatus will be installed. An attempt will be made to manufacture commercial by-products from smelter fume.

The Lane mill recently installed at the Midas mine is giving excellent results. It is understood that additional units may be installed this summer. Development is proceeding vigorously in the Midas and Gold Hill mines. The company plans to replace the old steam power-plant with an electrical system. The mines are located at Harrison Gulch, with C. A. Jackson manager.

H. F. Musser has started men working in the American mine, in the French Gulch district. A large tonnage of mill ore is exposed.

Gold mining is active near Stella, with Gambrinus, Bright Star, Mad Ox, and other properties in operation. On the 500-ft. level of the Gambrinus a vein averaging three feet wide has been developed, averaging $15 per ton. Five stamps are dropping. H. W. Rogers is manager. Activities at the Mad Ox are largely centred on the 600-ft. level, where the vein has been opened to the deepest working point. Sinking probably will be resumed soon. Oakland people are interested. W. H. McEwen is manager.

The Shasta Dredging Co. is building a new townsite near Gas Point, known as Smith's Center. Removal of the dredge from Horsetown to the new camp is proceeding.

Redding, May 10.

The Greenhorn mine in the western part of this county has been leased by Warren Bros. to M. E. Dittmar of Redding. Ore shipments in July last averaged 20% copper.

COLORADO

Boulder County

Buyers of tungsten ore at Boulder have advanced their quotations again; $8 per unit for 60% concentrate is now offered, against $5.80 before the War.

Gilpin County

Mills at Black Hawk are crowded with ore, while large quantities are waiting at the mines.——Shipments of ore from the Gilpin-Orion mine on Bobtail hill have returned up to 3.92 oz. gold, 7.6 oz. silver, and 2.8% copper.

Lake County (Leadville)

Ten burros have been purchased by the manager of the Lackawanna Belle, F. De Haven, to carry ore from this property in the Lackawanna district, for shipment to the smelter. Some rich gold ore has recently been opened.——The St. Louis is shipping about 75 tons of $30 oxide and sulphide ores per month.——Sixteen roasting furnaces are working at the zinc

smelter. The plant is working well. Another car of zinc oxide was shipped last week.

OURAY COUNTY

A 50-ton plant is to be installed by the Gold Crown Mining & Reduction Co. in the Foerster mill building near Ouray. Two crushers, rolls, tables, and flotation apparatus are being ordered. The company's mine is developing well. Ore worth $10 to $12 per ton is being opened. J. R. Roots is manager.

SAN JUAN COUNTY

Sixty-three cars of concentrate was shipped from Silverton during April. ——The Intersection 10-stamp mill has started for the season.——Lessees at the Ledge mine have a large tonnage ready for the mill on that property.——Machinery has arrived for the Kittimac mill.——Work has been resumed at the Champion and Old Green Mountain mines.——The Wilfley plant, which treats tailing from the Silver Lake mill, is to be started by A. R. Wilfley. Multiple-deck tables are installed. ——The Amy and Highland Mary have resumed.

SUMMIT COUNTY

The leasing system is being tried at the King Solomon company's property at Frisco. Lessees are working on the No. 11 vein in the adit, which is 3700 ft. long.

The report of the Tonopah Placers Co., operating at Breckenridge, appears in the annual statement of the Tonopah Mining Co. of Nevada. From 2,995,256 cu. yd. of gravel dredged there was recovered 22,542 oz. gold and 4782 oz. silver. The average value was 15.5c. per yard. The profit was 9.6c. per yard. Gross value of bullion was $467,204. The net profit was $176,677. Adding the previous surplus the total on February 28, 1915 was $269,580. The Tonopah Mining Co. holds 83.3% of the Placers company's shares. There remain 4836 acres to be dredged.

IDAHO

SHOSHONE COUNTY (COEUR D'ALENE)

Trouble over apex rights has arisen between the Pandora and Snowstorm copper companies. The former alleges that the latter has extracted ore from part of its property. The Court is asked for permission to inspect and survey the underground workings of the Snowstorm.—The Gold Hunter mill is reported to be making 90% extraction of minerals in its ore. Flotation is aiding the recovery.——Work is to be resumed at the Idora mine and mill near Wallace.——An Ingersoll-Rand 2500-cu. ft. compressor has been installed in No. 6 adit of the Morning mine.

MICHIGAN

HOUGHTON COUNTY

Amygdaloid ore from the New Arcadia was recently treated at the Franklin mill. From 1870 tons stamped the output of mineral (66% copper) was 59,045 lb. This is equal to about 30.5 lb. per ton. At 900 ft. depth the lode is 16 ft. wide.

McDonald and Cole have secured a contract to diamond-drill 75,000 ft. on the Smith land in the Porcupine-White Pine district. Six drills will be used.

MONTANA

SILVERBOW COUNTY

A large crowd witnessed the safety-first contest at Butte on May 9. The final winners were as follows: One-man event, Leonard mine team, first; Poulin mine team, second. Two-man event, Washoe Reduction Works' team, first; West Colusa mine team, second. Team event, Anaconda mine team, first; High Ore team, second; Washoe team No. 16, third. Highest general average for all of the events, Leonard mine team, 99.25%; Washoe team No. 16, 98.71%; and Anaconda mine team, 98.4 per cent.

The April pay-roll of the Butte district for 12,000 men was about $1,170,000. Miners are receiving $3.75 per day under the present agreement depending on the price of copper.

Furnaces at the East Butte smelter were blown-in on May 11.

NEVADA

CHURCHILL COUNTY

The Nevada Hills company reports as follows for the first quarter of 1915: ore treated, 17,007 tons; yield, $88,335; profit, $3991; net resources, $260,678. Development amounted to 1642 feet.

HUMBOLDT COUNTY

Bullion valued at $32,500, the first from the new mill at Rochester, was sent last week to the Selby smelter. This was from the Big Four, Codd, and Four Jay leases. They are supplying 35 tons daily each.

MINERAL COUNTY

Rich ore has been opened in No. 4 rise in the Lucky Boy at Aurora. This mine was part of the Aurora Consolidated before it was sold last year. A 5000-ft. adit is being driven to drain and prospect the ground.

NYE COUNTY

The Tonopah Extension, Victor, and Merger properties have been consolidated. The first named is to purchase the others and assume their debts. One share of Extension will be paid for seven of Merger, and one for eight and a half of Victor.

During the second week of May, Tonopah mines produced 10,617 tons of ore valued at $217,066.

April returns were as follows:

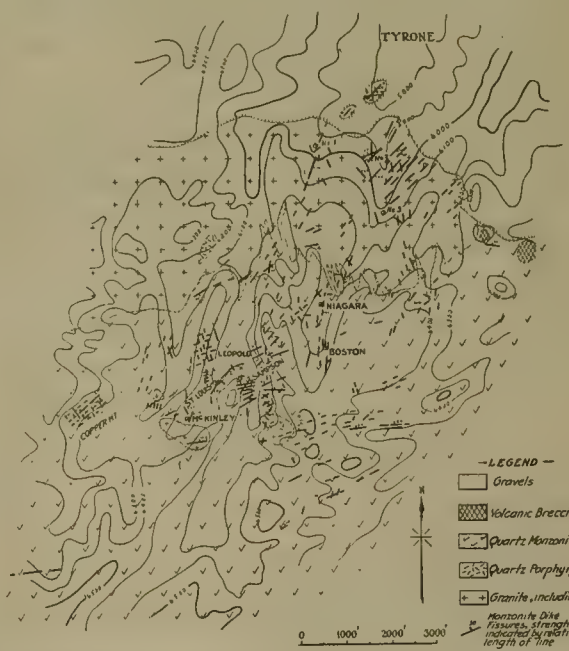
Mine.	Tons.	Ounces bullion.	Profit.
Belmont	14,661	273,201	$90,113
Jim Butler	4,590	.....	43,431
Tonopah Mining	11,925	211,080	63,845

The West End treated last week 783 tons from the West End, 107 from the Halifax, 258 from the Merger, and 52 from the North Star.

NEW MEXICO

GRANT COUNTY

In a 40-page illustrated paper, to be read at the September meeting of the A. I. M. E. at San Francisco, R. E. Somers



GEOLOGICAL MAP OF THE BURRO MOUNTAIN COPPER DISTRICT.

discusses the geology of the Burro Mountain copper district. The elevation of the area is from 6000 to 8054 ft. The climate is arid. Two classes of ore deposits occur, namely,

quartz veins with gold and silver, and copper ores in fracture zones with more or less disseminated replacement of the walls. The former have not been extensively worked. The latter have attracted considerable attention. At Tyrone the Burro Mountain Copper Co. is preparing for the ultimate production of a large tonnage of ore. The accompanying map shows the chief features of the district. In the building of the town of Tyrone, Phelps, Dodge & Co. purpose spending $200,000.

OKLAHOMA

Oklahoma was the only one of the Central states which showed a larger output of both lead and zinc in 1914 than in 1913. The value of the silver, lead, and zinc produced at mines in Oklahoma in 1914, as stated by J. P. Dunlop, of the U. S. Geological Survey, was $2,019,973, compared with $1,855,217 in 1913. The metal content of lead concentrate increased from 6228 tons, valued at $548,064, in 1913, to 7556 tons, and $589,368, in 1914; and the recoverable spelter increased from 11,664 tons, valued at $1,306,368, to 13,992 tons, and $1,427,184.

UTAH

Juab County

Ore shipments from Tintic last week totaled 147 cars.——It is now proposed to erect a large custom plant for the district. The Knight and Dern companies are said to be behind the movement.——The Ridge & Valley Mining Co. plans to resume work on June 1. It owns 351 acres of ground near Eureka. A shaft is down 800 ft. Considerable ore has been extracted. For some years lessees have done the only work in the property.

Salt Lake County

The Kennebec Mining Co., whose property of 400 acres in the Alta-Cottonwood district includes the Reed and Benson mines, is to extend its operations. Work at present is done by a cross-cut adit driven 1000 ft. It is proposed to drive another adit, lower down, to cut the vein at a vertical depth of 1100 feet.

Summit County

Ore shipments from Park City in April totaled 6948 tons. The producers were: Silver King Coalition, 3545; Daly West, 1066; Daly Judge, 1519; Silver King Consolidated, 262; Mines Operating Co., 462; and Charles Moore, 99 tons.

The recent report of the general manager of the Daly-Judge Mining Co., George W. Lambourne, covers the year 1914. The superintendent, O. N. Friendly, states that development amounted to 11,559 ft., excluding work done in ore. On account of the metal markets no ore was produced from August 10 to September 20. The mine is in splendid condition for supplying ore. The output during the year was 5606 tons of shipping ore, while 49,095 tons was concentrated. The former had the following average metal content: silver, 29.65 oz.; gold, 0.027 oz.; lead, 19.29%; copper, 1.51%; zinc, 12.37%; and iron, 7.40%. The mill produced 12,543 tons of concentrate, assaying 24.01 oz. silver, 0.04 oz. gold, 29.19% lead, 0.87% copper, 11.66% zinc, and 18.02% iron. The total metal content was as follows: silver, 519,979 oz.; gold, 723.6 oz.; lead, 9,675,220 lb.; copper, 384,782 lb.; and salable zinc, 3,548,896 pounds.

Ore sales realized $508,802, mining cost $167,731, and concentration $37,488, and all charges $376,618. A dividend totaling $180,000 was paid, the previous surplus being drawn on to the extent of $52,197. The balance on January 1, 1915, amounted to $440,153.

The Snake Creek tunnel was advanced 3751 ft. during the year, according to the engineer, Guy R. McKay, the best month being August, when two machines drove 419 ft. At the beginning of the current year the tunnel was in 10,448 ft., at a depth of 2500 ft. from the surface.

Many improvements were made at the mine. These added greatly in increasing labor efficiency and safety of operations, as well as lowering costs. The progress for all two-man machine headings has practically doubled, notwithstanding the fact that machine-men are now required to do their own timbering. Two-thirds of the distance driven is required to be timbered. In some of the drifts where timbering was unnecessary high records were made. The fast rate of advance has been in a measure due to the adoption of a premium system. This has worked to the mutual advantage of the company and the miners.

One of the most interesting parts of the mill report is that showing results obtained by a flotation process. During the latter half of the year a 40-ton mill was operated. This gave a high recovery of metals. The only difficulty experienced was in making a separation of the concentrate into desirable lead-silver and zinc products. Results have been sufficiently encouraging to justify the installation of a ball-mill for the purpose of making a test-run after regrinding the entire table-feed and jig tail, preparatory to treatment by flotation.

The cost-sheet shows that extraction costs for the 54,701 tons taken out were $3.067. In the mill account the concentration cost of 49,095 tons treated was 76.3c. per ton. The general expense cost against all ore extracted was 44.8c. The operating cost was $4.656. Marketing of the 22,201 tons of ore and concentrate was $1.124.

Utah County

A 5000-ft. adit is to be driven by the Major Evans Consolidated Mines Co. in American Fork cañon. It is already in 400 ft. At 4000 ft. it will be at a vertical depth of 2000 ft. A number of properties can be operated from this adit. It will also serve for transport and drainage.

WASHINGTON

Whatcom County

(Special Correspondence.)—After years of inactivity the Mt. Baker mining district is showing signs of a revival. Share-selling schemes and poor management characterized former work. A number of companies will commence work this season. The Hammond Mining Co., owner of the Great Excelsior mine, has been reorganized with a capital of $500,000. Control is held by Fred J. Wood and Frank Wright, both well known at Seattle. F. C. Hammond is general manager. A cyanide plant costing $150,000 will be complete in about three months. A 20-stamp mill and two re-grinding mills are already erected. The previous company, the Great Excelsior, only saved 39% of the gold in the ore milled, and paid $17 per ton for concentrate shipment to Tacoma. The mine has been well developed by 2500 ft. of adits and considerable stoping. The ore assays from $4 to $20 per ton.—— The Boundary Gold or Lone Jack claims are to be worked by G. H. Thomas and S. Q. Clark of Seattle. Three 12 to 36-in. veins of $15 free-milling ore have been opened. An air-compressor and drills will be installed. Five stamps are ready for crushing.

Bellingham, May 1.

CANADA

British Columbia

After being idle for several months the Standard Silver-Lead company's mill at Silverton is to resume work. Between 175 and 200 men will be employed at the property. Ore sales in 1914 amounted to $712,026. From 14,487 tons milled was produced 4154 tons of concentrate averaging 65.75% lead and 103.31 oz. silver per ton, and 5618 tons of ore assaying 43.84% zinc and 35.23 oz. silver. There was also shipped 4714 tons of crude ore containing 49.17% lead and 86.65 oz. silver per ton. Costs were $4.97 per ton mined. The surplus on December 31, 1914, was $170,000. Dividends were paid in 1914.

Ontario

The report of the Nipissing Mining Co. for 1914 contains the following information: Development totaled 12,148 ft. Prospecting by hydraulicking covered 96 acres. Ore reserves are estimated to be 2824 tons containing 5,034,838 oz. silver and 222,610 tons with 4,982,238 oz., a total of 10,017,076. The

high-grade mill treated 929 tons of Nipissing ore averaging 2439 oz. per ton and 965 tons of 2421-oz. ore from other mines. The low-grade plant treated 79,125 tons, yielding 2,261,924 oz. The refinery shipped 6,300,117 oz. Revenue in 1914 from all sources was $2,558,733. The cost of producing 4,689,333 oz. of metal from 80,037 tons of ore was $11.60 per ton, or 19.8c. per ounce. Net profit was $1,578,715. Dividends amounted to $1,380,000. On January 1, 1914, the surplus was $1,259,061, at the end of 1914 it was $1,602,776. Dividends to date are $13,233,297.

The McIntyre Mines Co. held its annual meeting on May 5. The year ended March 31, 1915, resulted in a loss of $12,000. In April net earnings from the mill were $40,000.——An electric hoist with a capacity of 5000 tons per day from a depth of 1500 ft., is to be installed at the new central shaft of the Hollinger, Acme, and Millerton properties.

Unwatering Cobalt lake is making good headway. It is expected that it will be empty at the end of May. There is a good depth of mud in it, which will take some time to remove. During April the Nipissing high and low-grade mills treated 132 and 5206 tons of ore respectively. The output was valued at $170,577. Adding custom ore the yield was $380,921. Hydraulic prospecting was resumed on April 22. Development at No. 73 shaft was encouraging.

Nickel ore shipped from the Alexo mine from April 7 to May 1 totaled 665 tons.

YUKON

Two of the Canadian Klondyke company's dredges started again on April 17 and April 19, respectively. No. 4 was receiving a further overhaul, but was expected to start by the end of the month. No. 2, which capsized in October last, is not yet ready.

KOREA

The Seoul Mining Co., operating the Suan concession in Whang Hai Province, reports the following results for April:

Total recovery	$78,000
Operating expenses	26,000
Net earnings	$52,000

Construction of the new 400-ton mill at the Tul Mi Chung mine is proceeding satisfactorily. It is expected to commence operating about August 1.

Cable advice from Korea to New York states that the Oriental Consolidated company's output in April was $139,300. In March the mills and plants treated 23,500 tons, yielding $145,365. Extraction at the Taracol plant was 92.3%. At the Maibong tube-mill recovery was 72%. Transport is still delayed by the cattle disease.

MEXICO

EL ORO

A recent telegram from the Esperanza company to London states that No. 3 rise on the Descubridora vein is up 148 ft. above No. 3 level. The last 70 ft. shows 17 in. assaying 1 oz. gold and 24 oz. silver per ton. The mill is not working. The property is intact.

SONORA

Shipments through Agua Prieta to Arizona in April amounted to 26,280 tons. Of this, 25,884 tons was concentrate from the Moctezuma company's plant at Nacozari. El Tigre shipped 132 tons, also 105 bars of bullion weighing 12,160 lb. The total estimated value of the traffic was $3,744,000.

NICARAGUA

An option has been taken on the Tunky Mining Co.'s Potosi mine by the Tonopah Belmont Development Co. of Nevada. The property consists of 265 acres. There are also placer rights along two rivers for 30 miles. Water-power is available. The claims are 20 miles from the Eden mine of the Tonopah Mining Co. Pittsburgh people own the La Luz and Los Angeles nearby. The latter have been highly profitable.

PERSONAL

SPENCER PENROSE is at the Fairmont.

C. S. HALEY is at Bridgeport, Oregon.

FRED S. ELY is at Houghton, Michigan.

GEORGE S. RICE has gone to Los Angeles.

COURTENAY DE KALB is at Nacozari, Sonora.

SPENCER PENROSE is here from Colorado Springs.

GEORGE KISLINGBURY was here from Los Angeles.

HOWLAND BANCROFT is examining mines in Arizona.

COLIN TIMMINS is now at Angels Camp, California.

T. WALTER BEAM, of Denver, is visiting the Exposition.

FRANK R. SHORT has returned to San Francisco from Peru.

COREY C. BRAYTON is leaving San Francisco for Nome, Alaska.

W. H. LANAGAN has returned to California from Eastern Siberia.

H. C. BELLINGER passed through San Francisco on his way to Ely, Nevada.

E. L. WOLCOTT, assistant secretary of the American Mining Congress, is in San Francisco.

A. JOHN SUB is making an exploratory journey through the Athabasca and Peace river country.

J. A. KERNS succeeds P. F. ROGERS as manager of the Hypotheek mine, in the Coeur d'Alene.

W. F. FERRIER has received the honorary degree of Doctor of Science from the University of Alberta.

BRADLEY STOUGHTON has returned to New York, having completed his work on the International Jury of Awards at the Exposition.

ALVIN R. KENNER, superintendent for the Rio Plato Mining Co., attended a director's meeting in New York in April and left early in May for Mexico City.

RUSH J. WHITE has retired from the staff of the Federal Mining & Smelting Co. and is opening an office as consulting mining engineer at Wallace, Idaho.

Obituary

WILLIAM JOLLY, mining captain at the Baltic mine, was instantly killed on April 28 by a fall of loose rock on the 17th level. He had been a miner in the Michigan district for 33 years.

LEONARD ORYNSKI, SR., formerly of San Antonio, Texas, but for the past 15 years interested in the Canoas mines near La Paz, Baja California, Mexico, died at La Pas on April 29, at the age of 70 years, after an illness of four days from ptomaine poisoning. He leaves a widow, three sons, and two daughters. His son, John B. Orynski, who recently joined him in his mining enterprise, will continue the development of the property so long as conditions permit.

Schools and Societies

STANFORD UNIVERSITY held its commencement on May 17. There were 456 degrees conferred on students and graduates.

A phonograph-telephonic lecturer has been devised by the WESTERN ELECTRIC Co. of New York. It is in operation at the Panama Canal at the Exposition, San Francisco. This apparatus should be of service at colleges.

The PAN AMERICAN FINANCIAL CONFERENCE will be held at Washington from May 24 to 29 inclusive. Proceedings are to be opened by the President of the United States. Many important subjects relative to the Americas will be discussed.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, May 20.

Antimony	35 —35¾
Electrolytic copper	19¼—19½
Pig lead	4.45— 5.45
Quicksilver (flask)	$75.00
Spelter	13¾—14
Tin	45 —46½
Zinc-dust, 100-kg. zinc-lined cases	20

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, May 20.—Copper is dull nominally; lead is inactive but firm; spot and nearby spelter is extremely scarce.

COPPER

Prices of electrolytic in New York, in cents per pound.

Exports during the week ended May 1 totaled 15,351,637 lb., valued at $2,504,298. Of this, 8,029,020 lb. went to England, 3,472,633 lb. to Sweden, 2,042,432 lb. to Canada 896,715 lb. to Italy, 700,460 lb. to France, and 193,687 lb. to Brazil.

Anaconda held its annual meeting at Anaconda on May 19. Shares in the company were reduced from 6,000,000 at $25 to 3,000,000 at $50 par value.

Calumet & Hecla is reported to be mining 12,000 tons of ore daily. Michigan output in May is expected to be 26,000,000 pounds.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending

June	56.43	....	Dec.	49.27	....

The above quotations need no comment. They show the steady market of the past few weeks. London advice states that the tone is good, due to less arrivals of metal from abroad. Imports from Mexico via New York to England are small. An element of uncertainty is introduced by the fact that over £1,000,000 of silver is held in London on China account. At any opportunity deemed favorable for such an operation, China is prepared to unload a portion of its holding, possibly to be replaced later on. On April 26 silver prices rose, China suddenly offered freely, quotations dropped sharply. Exports from London to the East in four months were £1,877,000, against £2,726,000 in that period of 1914, a decrease of about 8,500,000 ounces.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Spelter in London jumped to £70 per ton (15c. per lb.) on May 19. Last week at Joplin ore prices ranged from $63 to $75 per ton.

The report of the Butte & Superior company for the first quarter of 1915 contains the following figures as to zinc production:

Ore treated, tons	117,860
Average zinc content, per cent	17.356
Concentrate produced, pounds	70,634,000
Average zinc content, per cent	52.9246
Metal in concentrate, pounds	37,382,742
Cost per ton of ore	$ 4.8664
Revenue from zinc, lead, and silver, etc.	2,011,511
Profit, estimated	1,163,157

On May 19 tin was dull and easy at 36.75 cents.

Eastern Metal Market

New York, May 14.

Copper is quiet. Nominal prices are strong. The domestic demand for lead is light. The market is firmer in the West. Nominal quotations for spot and nearby spelter are a little easier. The scarcity remains the great factor. Tin sold heavily following the sinking of the *Lusitania*. An upward trend in prices was quickly checked. Antimony prices continue to soar as never before. Aluminum is stronger.

COPPER

The week has been uneventful, domestic and foreign demand continuing quiet. There is a feeling that buying, either directly or indirectly for export, will be renewed on a large scale, therefore the market is strong. There is less re-sale metal offered. During the week 18.75 to 18.87½c. cash, New York, has been the range for electrolytic. In London the market for spot and future standard copper advanced over £2 per ton, May 12, but £1 was lost the following day. Electrolytic advanced 10s. to £89, May 12, and was unaffected by the decline in standard. The *Lusitania* incident did not have any great effect on the market. In her cargo were 111,762 lb. of ingot copper, and 260,000 lb. of sheet brass. The latter was valued at $50,000, copper and copper wire, $32,000; copper manufactures, $21,000; and ammunition, $200,000, according to the manifest.

Producers of electrolytic are now getting a larger share of the war business than they received prior to Lake becoming so well sold up. A choice brand of the latter has been sold in large quantity for August delivery at 23c. Good prime brands are obtainable at 21c., and less favored brands at around 20c. A dispatch from Houghton, Michigan, contains the announcement that June 12 the Calumet & Hecla Mining Co. will distribute a bonus of over $500,000 among the 10,000 employees of the Company and its subsidiaries. Last Autumn it passed its dividend, reduced wages 10 to 15% and placed its men on three-quarter time. Since the war demand developed, the men have gone back on full time, and their wages have been restored to the former scale. Some of the high-grade contract miners and foremen will receive about $200 each as their share of the bonus. Bridgeport and vicinity plants, where a great deal of copper is consumed, are not only working night and day, but in many cases factory extensions are being rushed to increase production. It is understood that practically all of the large orders for munitions of war were taken with satisfactory assurances that they would be completed regardless of the length of the war.

SPELTER

Prices for the week ended May 14 were almost entirely nominal. On that day 14 to 14.25c., New York, was quoted for prompt shipments of prime Western. Choice grades of brass mill metal are practically out of the market, while early June deliveries are difficult to obtain. Some complaint is heard that deliveries are lagging. Inquiries for early delivery outnumber the offerings. There has been renewed effort to depress the price, and with some effect, but the market is strong. Foreign inquiry and buying has subsided to an appreciable extent, but this is believed to be but temporary. Prices will not recede far while the war demand lasts, and this promises to increase rather than diminish. Keen interest is shown in the importation of Australian ore.

TIN

News of the destruction of the *Lusitania*, May 7, was followed by greater activity in tin than the market has seen in a long time. That day and the following one, usually an off-day in tin, probably 800 tons changed hands, all positions being called for. The price May 7 was 39.50c., but it mounted to 42c. the next day. Contrary to expectations the London market did not advance sharply on Monday, May 10, and the market here became easier and dropped to 40.50c. On May 13, the quotation was 39.50. At the present writing much more generous arrivals are in sight than has been the case of late. There is afloat 4095 tons, part of which is on four vessels *en route* from London. Arrivals this month total 1690 tons, 615 tons of which came from Batavia, and the remainder from England on six vessels.

LEAD

The market, since the last report, has been dull, but firm at 4.20c. New York. At St. Louis a firmer tone prevails, and 4.12½ is quoted. A peculiarity of the present situation is that buyers of carload lots can get a lower price in the West than can those inquiring for 1000 tons upward. The explanation is that the smaller buyers are regular consumers whose wants can be easily cared for, while those who might take the larger quantities are interested in war requirements and pay a premium. Carload lots have sold at 4.10c. f.o.b. St. Louis, while for large tonnages 4.15c. f.o.b., St. Louis, is quoted. On the whole the export demand has been lighter, and home consumers show no tendency to load up.

The Department of Commerce, Bureau of Foreign and Domestic Commerce, reports that the total quantity of lead remaining in warehouse March 31, 1915, was 17,081,952 pounds.

ANTIMONY

A market price cannot properly be placed on English brands of antimony. An instance is heard of where a consumer disposed of a couple of casks at 40 to 45c. per lb. Chinese and Japanese, all there is to be had, is quoted at 35 to 36c. A sale is reported at 38.50c. duty paid.

ALUMINUM

This metal is firmer although there appears to be little in the way of increased demand. With the *Lusitania* there was lost 144 packages of aluminum manufactures. Sales have been made at 19.50c. Quotations for prompt delivery metal, 98 to 99% pure, range from 19.50 to 20 cents.

Exports of metals, May 1 to 14, 1915 were as follows: copper, 11,720; lead, 3822; and spelter, 1769 tons. Since the beginning of the war 92,252 (gross) tons of spelter has been exported. The monthly figures are: August, 3079; September, 17,005; October, 9160; November, 11,381; December, 16,309; January, 13,660; February, 13,394; and March, 8264 tons.

COPPER PRODUCTION OF MICHIGAN; LEAD AND ZINC IN KANSAS.

The production of copper from the mines of Michigan in 1914, as reported by B. S. Butler, of the U. S. Geological Survey, amounted to 164,344,058 lb. against 135,853,409 lb. in 1913. The output of silver was 413,500 oz., against 295,173. Value of the copper was $21,857,759 in 1914 and $21,057,278 in 1913. The silver output was $228,665 in 1914, against $178,285 in 1913. The production of refined copper in 1914 was 158,009,748 lb., compared with 155,715,286 lb. in 1913.

The value of the lead and zinc produced from mines in Kansas in 1914 was $1,260,870, against $1,343,432 in 1913. The decrease was due to the lower prices of spelter and lead and to the decline in the galena output from 3102 tons in 1913 to 1808 tons in 1914. All the mines in the Badger-Peacock district were idle, and the production of the Galena district was less in 1914 than in 1913. The Lawton district was active, several new concentrating plants were in operation, and the mine output was about double that of 1913.

COMPANY REPORTS

PHELPS, DODGE & COMPANY

With an authorized capital of $50,000,000, $45,000,000 issued, this Company controls the following operating companies: Copper Queen Consolidated Mining Co., Detroit Copper Mining Co. of Arizona, Moctezuma Copper Co., Burro Mountain Copper Co., Stag Cañon Fuel Co., and the Phelps-Dodge Mercantile Company.

The total copper ore extracted from the mines amounted to 1,777,243 tons, of which 1,046,728 tons was submitted to preliminary concentration, and 730,515 tons smelted direct. The quantity of copper made during the year 1914 by the constituent companies controlled by Phelps, Dodge & Co. was 140,231,384 lb., of which 8,569,060 lb. was made from the Miami company's ores, and the resulting product in blister copper was delivered to them. Including copper received from outside sources, 188,687,378 lb. was sold and delivered to buyers at an average price of 13.57c. per pound, net cash f.o.b. New York.

The president, James Douglas, states that the current of the copper trade has been deflected from its normal channels, like other markets of the world, by the war which started on August 1. From January to August the demand for copper was more sluggish than it had been in 1913. During the period from August to December both the domestic and foreign demand fell off to such a degree that it became imperative to reduce production. The output of the Douglas and Detroit smelters was contracted 40.48%. As a result, copper shipments from the smelting works of the Company during this period were only 59.34% of normal. The revolutionary movements in Mexico have slightly embarrassed operations there and correspondingly reduced the output.

At both the Copper Queen mine and at the mines of the Moctezuma Copper Co. the visible reserves have been notably increased, and improved methods in both mining and smelting have reduced the cost of production. The tendency of legislation in the new state of Arizona has been somewhat radical, but the people as well as their representatives recognize the dependence of the state on the prosperity of mining, and may be counted upon to encourage rather than depress that industry, even though some drastic experiments may be tried before an equitable system of state regulation and taxation will be reached.

The general manager, Walter Douglas, briefly covers the various operations and said that the financial loss involved through the reduced output of the Copper Queen smelter during the later months of the year was partly compensated for by the lower cost of both mining and smelting. The departmental reports show that the ore reserves at the Copper Queen mines have been increased, and that the radical changes recently introduced in the smelting plant, to meet the larger percentage of sulphur in the ore, and the growing volume of concentrate, have increased the savings and reduced the costs.

The Company's revenue from subsidiaries was $6,350,000, and commissions, etc., $541,651, a total of $6,891,651, of which $6,300,000 was paid in dividends. The surplus is $7,011,109. During the year the Tombstone Consolidated property was acquired, and will be operated under the name of the Bunker Hill Mines Company.

Reports of the subsidiaries contain the following information:

Copper Queen Consolidated Mining Company

The general manager, S. W. French; mine superintendent, Gerald Sherman; and smelter superintendent, F. Rutherford, included the following in their statements of their respective departments:

The Limestone mine reserves have increased from 211,199 to 257,077 tons of lean sulphide, and 2,357,729 to 2,834,862 tons of mine run ore. Most of the porphyry ores of Sacramento hill must be submitted to preliminary concentration. Methods of mining in 1914 showed the following: square set, 76.1%; top slice, 13.9%; cut and fill, 8.2%; and shrinkage, 1.8% in 694,942 tons extracted. Stoping costs were reduced.

The smelter treated 654,669 tons of Copper Queen ore and other material, averaging 6.25% copper, 0.02 oz. gold, and 1.01 oz. silver, yielding 76,842,973 lb. copper, 14,987 oz. gold, and 627,612 oz. silver. The total material treated in the plant amounted to 1,012,177 tons, yielding 119,957,017 lb. copper, 1,405,301 oz. silver, and 26,259 oz. gold. This included concentrate from the Moctezuma in Sonora, and custom ore. There were 946 men employed in the departments.

Ore shipped to El Paso amounted to 23,930 tons, containing 8,889,175 lb. lead, 399,106 lb. copper, 332,106 oz. silver, and 1822 oz. gold. The experimental plant also treated 3150 tons for 130,342 lb. copper.

The Copper Queen metal output was 86,066,143 lb. copper, 8,889,175 lb. lead, 1,036,672 oz. silver, and 15,769 oz. gold, from 732,829 tons of ore, precipitate, and slag. Net earnings totaled $6,042,001, and $4,500,000 was paid in dividends.

The report contains a great deal of interesting matter on experimentation, accidents and safety, and the hospital department, which will be dealt with separately in other issues of this journal.

Detroit Copper Mining Co. of Arizona

The reports of the general manager, A. T. Thomson; mine superintendent, M. H. McLean; and smelter superintendent, V. P. Hastings, contain the following data:

Development amounted to 12,766 ft. in the five principal mines, and 13,609 ft. in outside properties, a total of 26,375 ft. Ore production was 217,876 tons from the Ryerson mine, 85,119 from the Yankie, 128,641 from the Copper Mountain, 39,310 from the Arizona Central, 1202 from the Colorado, and 46 from the Antietam, a total of 472,194 tons. This averaged 2.899%. Out of this tonnage, 459,473 tons was concentrating ore. Lessees mined 773 tons containing from 4.71 to 21.19% copper from 13 mines, and 61.7 tons of precipitate averaged 52.13%. Exploration on the outside property was not encouraging and ore reserves decreased, in spite of good results in the Ryerson and Yankie.

The blast-furnace smelted a total of 129,530 tons of mixed charge, and the output of copper was 20,274,367 lb. Net earnings for the year were $602,319, and $280,000 was paid in dividends. There were 1438 men employed.

Moctezuma Copper Company

This Company, in charge of J. S. Williams, Jr., operates at Nacozari, Sonora, Mexico, and has been the scene of revolutionary movements for some time past, and the general manager states that nothing but the political unrest in the country would prevent the property being a more active producer than it has been.

Mining operations show an increase of 500,000 tons of ore in reserve. The Pilares, the main hoisting shaft, was sunk to 1285 ft., and a little work there exposed a considerable tonnage of good average-grade ore. The Esperanza and Guadaloupe shafts are down 1266 and 1000 ft. respectively.

The mill produced 120,655 tons of concentrate, which, with some slime and other ore, was shipped to the Copper Queen smelter at Douglas. It contained 1006 oz. gold, 435,482 oz. silver, and 32,229,211 lb. copper.

Net earnings totaled $1,189,100, and $1,170,000 was paid in dividends.

Burro Mountain Copper Company

This Company's property at Tyrone, New Mexico, was described in the *Press* of February 6, 1915. Mining operations consisted in the development of the so-called Bison orebody cut while driving the main tunnel from Tyrone to the east-

ern orebody in the Leopold property. In addition to exploring it, the best method of attacking the Tyrone deposits has been carefully studied, according to the superintendent, E. M. Sawyer. The hoists of No. 2 and 3 shafts on the Chemung property have been replaced by machinery of greater capacity, and the shafts themselves are being overhauled for active service. Churn-drilling operations have been systematically carried out during the year. Thirteen holes, with an aggregate of 11,571 ft. have been drilled, as might be expected, with variable results. They will prove valuable as guides when looking for new ore.

The first of the two 1000-hp. Diesel engines was started, the second is being installed, while a third will be needed as a stand-by. Systematic experiments were made in treatment of the ores. Although selection of a townsite was difficult, owing to the broken character of the country, one was set out about midway between the mill and the mouth of the main tunnel and the two principal Chemung shafts. The sum of $25,000 was donated by Thomas S. Parker for a new public hospital, and the Company will add an equal amount.

The year ended in a deficit of $267,180, the balance at the end of the previous year being $158,179 at credit.

Stag Cañon Fuel Company

This Company operates a coal mine and coke ovens at Dawson, New Mexico. T. H. O'Brien is general manager and J. B. Morrow superintendent of the coke department.

Development in five mines amounted to 30,998 ft. of entry driving, an increase of 772 ft. over that in 1913. The production of coal amounted to 1,355,938 tons, an increase of 33,125 tons. There were five fatalities underground. The washery handled 517,736 tons of coal, and the coke output was 239,966 tons, a decrease of 53,123 tons, due to conditions in the copper industry. Net earnings amounted to $297,785.

Phelps-Dodge Mercantile Company

The general manager, W. H. Brophy, reports that sales in the stores at Bisbee, Dawson, Douglas, Morenci, Nacozari, Tyrone, and Pilares totaled $5,920,233, on which the net profit was 8.38%. Net earnings were $460,656, and dividends amounted to $400,000.

CANADIAN MINING & EXPLORATION CO., LTD.

In 1914 this Company completed its full season of active search in the field for mining properties. A large number of investigations were made in British Columbia, Alberta, Saskatchewan, Manitoba, Ontario, Quebec, Yukon Territory, Alaska, Arizona, California, Colorado, Minnesota, Missouri, Nevada, New Mexico, Oregon, South Dakota, Mexico, and Cuba. In the examination of newly opened districts, Canada continued to receive particular attention. Of the properties considered, several had merit, and would have justified exploitation under favorable terms. Up to the end of 1914 no business had been concluded that justified a call on shareholders for subscriptions. The gross income was $137,596, and expenditure $99,732. Investments are valued at $2,136,812. Current assets include $321,446 cash. W. W. Mein is consulting engineer.

ALLOUEZ MINING COMPANY

Results of this Michigan copper company during the past three years may be compared from the following table:

	1914.	1913.	1912.
'Rock' stamped, tons	354,457	236,663	333,618
Refined copper recovered, lb.	6,056,548	4,091,129	5,525,455
Refined copper sold, lb.	6,056,548	3,819,324	4,367,964
Average price received, cents per pound	12.853	15.672	16.668
Total revenue	$791,821	$650,205	$918,435
Cost, cents per pound	11.18	12.09	13.52
Net profit	$114,530	$155,728	$171,264
Balance, assets over liabilities	363,822	249,292	93,564

Work was resumed at full capacity on February 1, 1915.

MINING DECISIONS

Timber Cutting on Mining Claim in Forest Reserve

Jurisdiction over matters relating to the cutting of timber on lands within the surface areas of mining claims located in national forests is vested exclusively in the Department of Agriculture. Officials of the Department of the Interior will not interfere in such matters.

H. T. Mecum, 43 Land Decisions, 465.

Possession of Surface Not Possession of Severed Mineral Rights

After a severance of minerals in place from the surface above them, the acquisition of title to the surface by adverse possession thereof does not result in the acquisition of title to the mineral interests of the land. To acquire by adverse possession the title to the mineral interest so severed, there must be an actual taking or use under claim of right of the minerals from the lands for the period necessary to effect a prescriptive title.

Birmingham Fuel Co. *v.* Boshell (Alabama), 67 Southern, 403. December 17, 1914.

Discovery Must Precede Application for Patent

A mining location is not perfected or completed until a discovery of mineral within the limits of the claim has been made; and where no discovery was made prior to the filing of an application for patent, such application and the proceedings thereunder, being without legal foundation, cannot be recognized as a basis for mineral entry or patent, even though a discovery be made after the filing of the application and after the expiration of the posting and publication of notices thereon.

Bay City Oil Co. *v.* Alvarado Oil Co. (Land Department), 43 Land Decisions, 397. September 19, 1914.

An Act to Provide for the Leasing of Coal Lands in the Territory of Alaska, and for Other Purposes

Section 3. * * * And provided further, that any person, association, or corporation qualified to become a lessee under this Act and owning any pending claim under the public-land laws to any coal lands in Alaska may, within one year from the passage of this Act, enter into an arrangement with the Secretary of the Interior by which such claims shall be fully relinquished to the United States; and if in the judgment of the Secretary of the Interior, the circumstances connected with such claim justify so doing, the money paid by the claimant or claimants to the United States on account of such claim shall, by direction of the Secretary of the Interior, be returned and paid over to such person, association, or corporation, as consideration for such relinquishment. * * *

Sec. 15. That on and after the approval of this Act no lands in Alaska containing deposits of coal withdrawn from entry or sale shall be disposed of or acquired in any manner except as provided in this Act: Provided, that the passage of this Act shall not affect any proceedings now pending in the Department of the Interior, and any such proceeding may be carried to a final determination in said department notwithstanding the passage hereof: Provided further, that no lease shall be made, under the provisions hereof, of any land, a claim for which is pending in the Department of the Interior at the date of the passage of this Act, until and unless such claim is finally disposed of by the department adversely to the claimant.

Approved October 20, 1914.

The foregoing are the only provisions, in the recent Act of Congress, providing for any preference or protection to be given to locators of coal lands under prior laws.

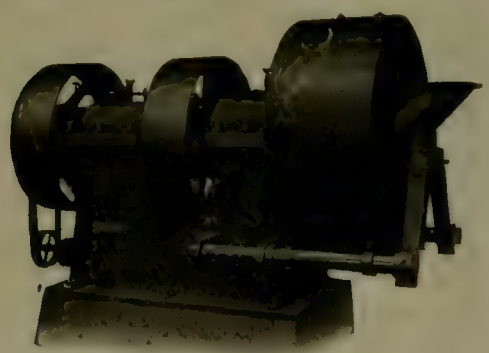
New Machines and Devices

Information based on letters and catalogues from manufacturers.

Disc-Crushers

In the *Press* of May 8 it was stated that Symons disc-crushers were to be used at the new 14,000-ton mill of the Inspiration company, Arizona. *Section* R, fourth edition, issued by Chalmers & Williams, Inc., of Chicago Heights, Illinois, describes these machines. The firm states that five years ago one such machine was at work; now there are hundreds.

The 36 and 48-in. machines are made of great strength for hard ores, and have a large capacity. Crushing is done between two discs of manganese steel. They are dish-shaped and are set with their hollow or concave sides facing each other, forming a cavity between them. These discs both rotate in the same direction at the same speed. The discs are supported at an angle to each other. This provides a wider opening between the edges of the discs at one part of their circumference than at the opposite part. When ore is fed through



SYMONS DISC-CRUSHER.

the central feed opening, it is thrown by centrifugal force into the opening where the discs are widest apart. It is carried around with them to where they are closer together, and is crushed by the operation. The smaller particles fly out from between the discs, into the encircling chute, while the larger particles are caught again and the operation repeated.

The two sizes mentioned have the following details:

	36-inch.		48-inch.	
Approximate shipping weight, lb.	23,500		39,000	
Size of feed, inches	3½		6½	
Minimum opening for best results, inches	¾		1	
Minimum capacity, tons per hr.	Size of ring.	Tons per hr.	Size of ring.	Tons per hr.
	¾	25–30	1	45– 60
	1	30–45	1½	60– 80
	1½	45–60	2	80–100
	2	50–65	2½	100–120
Main pulley speed, r.p.m.	133		100	
Eccentric pulley speed, r.p.m.	300		250	
Size of pulleys, inches	44 by 14		54 by 16	
Horse-power required	30 to 40		50 to 65	

Dust is prevented by paper coverings. Support of speed spout is adjustable. Shaft and eccentric bearings work in a bath of oil. All Symons disc-crushers are manganese equipped. The catalogue also describes the 48-in. Symons fine reduction disc-crusher. The Arizona Copper Co. is installing two 48-in. machines.

Portable Electric-Drills

The Western Electric Co. claims that its 'Temco' electric portable drills have been designed to give long and efficient service under severe conditions. These machines have the general shape of an ordinary breast-drill, are compact and light. The weight is well balanced, making handling easy. The electric switch is conveniently placed near the handle. A special feature is the ease with which the motor may be reversed when the drill jams. These drills will also tap holes, the reversing feature being here of great advantage. For working inside objects, or upside down, and in other inconvenient places, these portable drills are said to have no equal. The motors are constructed to operate on either direct or alternating current at standard voltages. Connection is made to the nearest lamp-socket by means of a flexible cord and attachment plug. The two principal sizes are models B and C. The former has one motor and the latter two. The former weighs 12 lb. and will drill ⅜-in. steel. The latter weighs 19 lb., and will drill ½-in. metal.

PORTABLE ELECTRIC-DRILL.

Commercial Paragraphs

A four-page pamphlet on the operation and cost of filter-presses in metallurgical work has been issued by WILLIAM R. PERRIN & Co., Chicago.

The SULLIVAN MACHINERY Co., of Chicago, announces that Robert J. Raley, representative in the iron and copper country of Michigan and Minnesota, is at room 910 Alworth building, Duluth, Minnesota.

A 36-page catalogue, No. 46, issued by the WITTE ENGINE WORKS, Kansas City, Missouri, deals with the firm's organization, shops, costs of running engines, details and superior points claimed for its oil engines for all purposes, and other interesting information.

The Exposition edition, *Bulletin* 52, of the BYRON JACKSON IRON WORKS, San Francisco, covers 48 pages with illustrations, and is described as containing useful engineering data pertaining to pumping problems. The subjects discussed are as follows: methods of developing water for irrigation, the amount of water used in irrigation, hints on irrigating different crops, methods of checking waste of water, measurement of water, conveying water, electric pumping, and cost of gasoline and current, and a considerable amount of useful information on pump details, pipes, efficiency, measuring water, and pumps suitable for mines. This firm manufactures a large variety of pumps up to 50-in. size driven by a 650-hp. motor. A. C. Paulsmeier is chief engineer.

Mining and Scientific Press

Volume 110 | SAN FRANCISCO, MAY 29, 1915 | Number 22

ON THE WHITE PASS RAILWAY, THE GATEWAY TO THE YUKON

THE CALL OF THE NORTH is heard again in these days when the ice breaks and the rivers are opened to navigation throughout the great mineral regions of Alaska and the Yukon. Already several new finds of gold are heralded from Nome and Dawson. We record these developments on our pages; also the new mining regulations in Alaska.

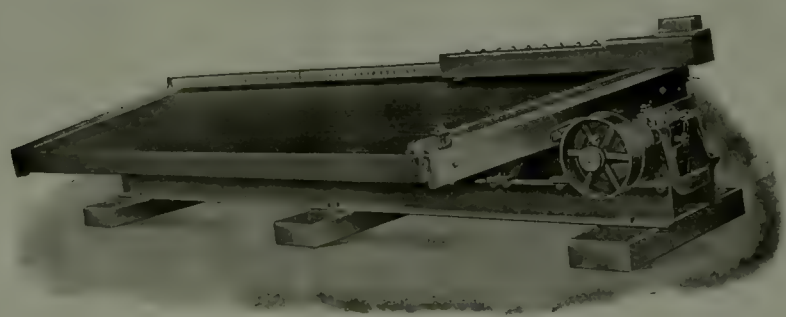
A FEW
Very Important Improvements
have been made on the card, making a cleaner concentrate as well as separating the middlings entirely from the gangue

YOU CANT MAKE GOOD SEPARATION

on a Concentrator with riffles projecting above the surface of the table. While it is true that they arrest the coarse mineral, the fines are inevitably excavated and washed over riffle after riffle, going thence into the creek. You need a table with *channels* cut below the surface of the table.

In other words, you need a *CARD.*

LET US SEND YOU DESCRIPTIVE MATTER



All patents valid and in force. Absolutely no litigation.

ARTICLES

GOLDFIELD RE-VISITED—II.
By T. A. Rickard 829
Extraction at the Goldfield Consolidated mill is now 92%; 8 lb. lime per ton was formerly added to the pulp, now 20 lb. per ton is required because of the increased acidity of the ore. Few changes in the mill have been necessary. Daily output of concentrate is 80 tons; this is roasted and cyanided after removing the copper by leaching with acid. In the boom days much gold was lost by 'high-grading.' Fortunes were made over-night and as lightly expended.

NOTES FROM SOUTH AMERICA.
By Mark R. Lamb 832
The Chuquicamata was started on May 15 by the President of Chile. Interest is shown in quicksilver mining; copper mines are hampered by the inability to secure freight room for their ore on account of the scarcity of ships; coke is scarce at the smelters and none is being received.

TECHNICAL REMINISCENCES—II.
By Albert R. Ledoux 833
Thirty-five years ago much American copper ore and metal was sent to Wales for smelting and refining. Sampling methods employed in Wales were to the disadvantage of the shipper. Ledoux & Co. was able to demonstrate that its method was more accurate and brought about a desirable change in practice, greatly to the shippers' advantage.

THE METALLURGY OF ALLUVIAL MINING.
By John M. Nicol 837
Attempting to save all the gold in alluvial deposits in a single operation is illogical, since the current required to keep riffles from filling with heavy concentrate is sufficient to carry away a good deal of gold. The gold is also not always free. Useful suggestions for the solution of the problem are made and will be discussed in the second article of the series.

SECONDARY SULPHIDE ENRICHMENT OF COPPER ORES.
By Arthur L. Day 841
Study of this important problem in economic geology is being carried on jointly by the Carnegie Institution of Washington and Harvard University. The director of the geophysical laboratory of the former lucidly sets forth the essential factors of the problem.

EDITORIAL

T. A. RICKARD - - - - Editor THOMAS T. READ - Associate Editor

BOLIVIAN tin concentrate is to be smelted in Chile. It is reported that a plant is to be erected at Arica or Mejillones.

NATOMAS re-organization is proceeding smoothly, the last obstacle being removed by the permission granted by the British Treasury for the London company to raise the necessary capital.

FLOTATION is being made applicable even to copper ores containing oxides; for instance, an extraction of 85 to 86% is being obtained on a 1.75% copper sulphide in which 0.2% copper exists in oxidized form.

SPECULATION in 'war stocks' is more risky than mining. The trade in munitions and armament is based on a demand exceedingly precarious as compared with the inevitable and persistent need of the metals.

CONSOLIDATION of the activities of the Anaconda Copper Mining Company is proceeding apace, the dissolution of the United Metals Selling Company having been announced. This was a subsidiary of the Amalgamated Copper that refined and sold the metal from the properties under the control of the latter. This part of the business will now be continued by the refining and selling departments of the Anaconda company.

ABSORPTION of the Stratton's Independence property, at Cripple Creek, by the Portland Gold Mining Company, is announced by our correspondent at Cripple Creek. The famous mine passes to its neighbor for $300,000, while the British company formerly owning the Independence will maintain its organization and acquire new property, not necessarily in the Cripple Creek district. We shall refer to the matter at greater length in our next issue.

ARCHANGEL is now open to navigation. A new Russian-American line has been established, the first steamer to leave New York for the White Sea being the *Czaritza*, on May 22. The resumption of direct communication between Scotland and Archangel is important to the many mining engineers attached to the companies operating in Siberia, for the normal lines of travel across Europe are barred.

CLAIRVOYANTS and crystal gazers receive respectful mention from the Commissioner of Corporations, Mr. H. L. Carnahan, who warns the public against the purchase of securities on the advice of such persons. It is recorded that during the past three years one clairvoyant disposed of 163,000 shares of mining stock to his 'clients,' paying 1 cent per share for the stock and selling it to his victims at prices ranging from 15 to 50 cents per share. The Blue Sky law offers some measure of protection to so-called investors in California, but its effectiveness only applies to issues made since December 19, 1914. If you want advice on mines, go not to those that study the stars but to those that watch the signs underground.

THE ONE-EYED is always eager to guide the blind. Recently, in a hotel foyer, we heard one man ask another what 'spelter' was? The second hastened to explain that it was "a sort of dross, composed of lead, zinc, and tin, and other impurities." Whereupon the first suggested: "A kind of pewter," to which the knowing one assented cheerfully. It is curious that the trade name of zinc should be 'spelter.' The latter word is derived from *spiauter*, a term borrowed from India in the 16th century, for the art of extracting zinc from its ores originated in the East. Arriving in Europe, the word became the old German *spialter*. 'Pewter' is a derivative from *spialter* through the old French *espeautre*, so that 'pewter' and 'spelter' are allied etymologically, although no longer synonymous.

WHILE the first evidence of Italy's participation in the War was regarded cheerfully on Wall street, as tending to shorten the duration of international hostilities in Europe, it is noteworthy that the quotations for 'war specialties' advanced on the New York Exchange, as if the demand for munitions would be greater, and longer presumably. Certainly American participa-

tion in the War, for which we have no wish or expectation, would intensify the need for manufacturing munitions and would tend to consume more metals in death-dealing apparatus. We would like to see the useful metals employed in the service of man, instead of his destruction, but we recognize that this aspect of the War has proved helpful to the mining industry to a degree unsuspected a few months ago.

SMELTER SMOKE abatement has reached a further point by the Supreme Court's decision, as between the states of Georgia and Tennessee, in the matter of the sulphurous fume emitted by the Ducktown Copper Company, in Tennessee. The Court rules that an inspector be appointed to limit the amount of deleterious smoke that may be diffused from the state of Tennessee into the state of Georgia. We trust that the inspector will use a scientific gauge for measuring the volume of noxious fume that crosses the line.

GOLDFIELD'S complexities are becoming straightened. On May 21 the deal between the Booth and Jumbo Extension companies was confirmed by the directors of the latter. That the place of consultation should have been Phoenix, Arizona, is a minor anomaly due to the custom whereby a company doing business in one state chooses to be incorporated in another, where restrictions are less onerous. By this arrangement, now in a fair way of being consummated, the Booth receives 300,000 shares of Jumbo stock, recently increased for that purpose, and $15,000 in cash, representing a dividend of 5 cents per share on the new issue of stock. In return the Booth transfers to the Jumbo all the ore in the Velvet claim. Thus an explicit side-line agreement is avoided, but the benefits of such an agreement accrue to the owners of the Velvet claim. Another effect of this method of settling the trouble is to help the Jumbo company in its defense against the Merger Mines, in case the latter presses its suit for a recovery of the Velvet claim. But we hope that this matter also will be adjusted without further recourse to the courts.

The Mining Industry

In our last issue we discussed one phase—the humorous or pathetic—of mining; this week we turn with satisfaction to the more important and more satisfactory phase that represents the real industry. The ultimate purpose of mining operations is to make money through the winning of the metals, by finding, extracting, and marketing them profitably. The rest is the frill on the outside. In places like New York and London, in localities like Wall street or Throgmorton street, or even Bush street, it is forgotten sometimes that the purpose of mining is not to create counters for a gamble, but to dig ore profitably. Fortunately we who live in San Francisco need not go far to see this basic operation being performed with a maximum of skill and success. A few days ago the present writer re-visited Grass Valley, where two notable examples of mining enterprise have been on view for many years. Indeed, we recall no locality where the mining industry wears a more benevolent look. The little town, founded 65 years ago, at the time of the first discoveries of gold in the district, is a pretty settlement, embowered in flowers and foliage. From the outskirts comes the muffled thunder of stamp-mills, which, themselves and their predecessors, have made sweet music for over half a century. Two mines, the Empire and North Star, have been in operation for over 60 years and productive under their present management for fully 30 years; yet today their vitality seems unimpaired. The Empire is 4800 feet deep on the dip and 2200 feet vertical, while the North Star has gone down to 6300 feet on the dip, or 2400 feet vertical, which is exactly the altitude of Grass Valley above the Pacific ocean. Since 1854 the Empire group has produced $13,500,000, while since 1851 the North Star properties have contributed no less than $18,250,000 in gold. Both are private properties in so far as neither has shares that are subject to public dealings; in other words, the ownership is divided among a few men, of large means, who have put their money into the enterprise just as they would invest it in a farm or a foundry. Indeed, in cases such as these, mining does become an investment, for capital is employed with a view to deriving an income, not with the idea of enhancing the value of the principal so as to be able to dispose of it at an advance. These two enterprises have prove abundantly profitable, for in each case the original capital has been returned many times, while all development and equipment has been paid out of revenue. Thus conducted, it will be confessed that mining is a pretty business. No one is robbed or injured. Dormant natural wealth is put into useful circulation. Workmen are employed and a community supported. Most of those working in these mines have their homes in the vicinity; many of them are the sons, or even the grandsons, of men that have found steady employment with the same company. Besides giving employment to a succession of technical men, these mines have served to train many engineers who are now doing good work in various corners of the earth. Finally, it is not impertinent to say that the mine-owners themselves include a number of our best citizens, men notable in other branches of industry. Viewed thus, the activities maintained at Grass Valley, aboveground and underground, will commend themselves not only to the engineer but to the philanthropist. It is mining at its very best.

We understand, of course, that mining thus conducted, as a private affair, has its disadvantages. Owing to the absence of a free market for the holdings of the various proprietors, their property in such mines is not a liquid asset. It can be sold only by negotiation with other partners in the business. Moreover, if all mining enterprises were conducted on a similar basis the capital available for mineral exploration and exploitation would be severely restricted, for only rich men can afford to buy large fractions of big mines. In this department of human activity, as in others, each extreme has its dis-

advantages. In order to distribute the risk of mining so that it will not cripple any individual it is convenient to divide the financial commitment among a large number of persons, and in order to enable such persons to withdraw their capital when occasion arises it is likewise convenient to arrange for a daily quotation of the subdivisions or shares in the enterprise. But the many good features of the clean method and wise policy of the private company can be imitated by the public joint-stock corporation without impairing its vitality or lessening its essential prosperity. Chicane is no more inherent in a company of a thousand men than in one of five. When practised it is usually at the expense of the many and to the gain of the few. All the boosting, booming, and balderdash of share-peddling, such as we described in these columns last week, operates to the public's loss, for it may be taken as axiomatic that the insiders unload on the outsiders. It is said that it promotes interest in mining; we doubt it, any more than the lottery stimulates interest in the resources of Louisiana. If it be a stimulant, it is like many others in being followed by a depressing reaction. Being false in its essence, it can only work for harm. We commend the Grass Valley example as an ideal.

Professors of Mining

The fact that at least four institutions of learning are looking for new heads of their mining departments gives timely interest to a subject that must always deeply concern those having at heart the welfare of the mining profession and of the industry to which it ministers.

At first sight it would seem as if professors of mining, like poets, were born, not made. Assuredly the effective teacher of this subject is rare. This is due partly to the enormous expansion of the technology involved and its world-wide application. The scope of knowledge required is staggering. Concurrently the increase in the number of students and the large size of the classes to which the professor must lecture introduces the second, and ever present, factor of personality. To hold the attention of his students, the teacher must have force of character as well as a large stock of information.

During the past decade those responsible for the selection of professors have become impressed with the idea that a teacher of mining failed to be effective if he lacked experience in the field; it has seemed to them that actual contact with the realities of industry was needed to enable the teacher to appreciate the ultimate purpose of the mining art, namely, to make money by exploiting mineral aggregates. In other words, they wanted the practical man: the practitioner in place of the academic authority. This notion became dominant. In its ascendancy it gave us one or two professors of the highest ability; their names will leap to mind, but the number of them is so small as to constitute exceptions rather than evidence in support of the new departure. As a matter of fact, expert teachers are made no more quickly than expert mining engineers or metallurgists. The eminent practitioner does indeed enter the lecture room with the vital air of the man that has done things in that world for which his students are preparing, but he is rarely a good expositor, and he is better used to managing grown men than disciplining youths. His knowledge of the subject is probably specialized in a particular direction, for no man can keep step with the advance in every branch of mining, least of all those who are fully occupied in a successful consulting practice or the absorbing administration of a mining enterprise. Indeed, the masterful acquaintance with the details of a particular business or special branch of industry is likely to militate against an express recognition of the fundamentals of the subject as a whole. In any case, such detailed knowledge does not carry with it the ability to convey the underlying principles from the practitioner's brain to that of a number of young listeners. Neither width of experience nor breadth of knowledge assures the aptitude to instruct others. The gift of clear exposition is not acquired over night; it may be latent, but in most cases it comes only from earnest effort and practice.

Despite one or two notable exceptions, therefore, we conclude that the successful practitioner is rarely endowed with the gift of teaching. The alternative is to give the trained teacher a chance to acquire first-hand knowledge in the field. To teach mining, or any art to which science is applied, requires a familiarity with the related sciences and the capacity to convey a supply of fundamental knowledge to those as yet detached from contact with actualities in the field. The training of the mind of the young in preparation for the post-graduate teaching of life itself is the aim of scholastic instruction. The professor of mining does not make mine managers and smelter superintendents, he prepares likely young men for that apprenticeship to minor posts which precedes promotion to positions of greater responsibility. No lecturer can give the practical training of which people speak so glibly; that comes only by actual participation in technical work. The minutiae of daily work are only confusing to students engaged in grasping the elements of their subject. They find it difficult to see the wood for the trees. Those elements are best taught by one who has learned how to teach, rather than to practice. He must be a student himself, and grow with his subject, which, in the case of mining, is undergoing rapid and constant development. To do so, he should be given an opportunity to spend his summer vacation among mines, mills, and smelters, away from his students, absorbing new ideas and acquiring new knowledge from those in charge of technical operations.

On the whole, therefore, it appears to us that the type of man best fitted for this special branch of instruction is one who has been first an eager student and then a trained teacher of the sciences applied to mining, a man preferably of general culture and wide sympathy, a man with the inborn thirst for knowledge and the acquired ability to convey it to others. We should select an alert young man, expecting him to grow with his work, and develop in the course of his teaching to that splendid

fitness that makes the true expositor and the effective educator. But, to supplement the inevitable deficiences of individual teaching, we should advise the authorities of a mining school to invite distinguished practitioners to give short courses of lectures on special subjects. That is where the practitioner is invaluable. He is a man who has done things, his lectures will illustrate the principles elaborated by the professor, and his reference to work accomplished will serve to heighten the student's interest in the regular lectures from the chair. If possible, sundry mining engineers should give three or four lectures on special subjects regularly from year to year, so as to maintain the continuity of instruction. This method, if done in a cordial spirit of co-operation, should give the students the best preparation for taking a useful and successful part in a great industry.

Copper in Ammunition

Among the many and varied uses of copper, its consumption in the manufacture of ammunition is not the least important, as is attested by the fact that some 20,000,000 pounds of copper is used for this purpose each year in the United States alone, in spite of the small degree to which military preparation for war is here developed. Within the past few months huge orders for the ammunition required in Europe have been placed with firms in this country, many of them concerns formerly engaged in making other kinds of goods, but who are not unwilling to modify their plants and procedure in order to benefit by the high prices paid for quick delivery of the various munitions now being consumed so lavishly. It is impossible to estimate how much copper is now being used for this purpose, but some idea may be gleaned from the way in which the price of the metal has risen in the past few months, and continues to rise in spite of the efforts of the mining companies to increase their output.

When copper in ammunition is mentioned the natural association is with the brass cartridges used for ordinary rifles. Greater interest attaches to the cartridge cases for quick-firers and field-guns. The case of the cartridge for a 3-inch gun weighs 1 lb. 5 oz., while that for a 6-in. gun weighs 28 lb. 14 oz. As in a million rifle-cartridges only 23,000 to 26,000 lb. copper is used, it is seen that the greater weight of the larger cartridges tends to compensate for the less frequency with which they are fired. But there are other uses of copper in ammunition. Every shrapnel shell must have a copper band about it in order to prevent the escape of the gases of the explosion past the projectile; these rings average 2½ to 3 lb. in weight per shell. The copper expands under the impact of the explosion and makes a tight fit against the sides of the gun. This saves the wear caused by the rush of the gas past the projectile, and increases the power of the gun; it also makes the projectile follow the rifling better.

Every cartridge requires a primer; these are made of copper or a soft brass rich in copper. The old-style lead bullet is not suitable for use in the modern high-power rifles, so the projectile is commonly made with a hard jacket over a lead core. An alloy of 85% copper and 15% nickel is the most suitable for this purpose. The Germans use sheet-steel cases for bullets, plating them to protect them from rust. The steel is believed to wear the rifling of the barrel more rapidly than cupro-nickel, but does not foul it so quickly, being harder. One of the armies of Europe uses a solid brass bullet. The lead used in all projectiles, especially shrapnel, contains antimony, hence the present demand and high price of that metal.

Spelter advances with the demand for copper in war. The brass used in the making of ammunition must be of the best quality, containing about 70% copper and 30% zinc, so it will not crack in working, nor be destroyed in firing, as all cartridges are re-loaded. The specifications of the United States Army require cartridges to stand 20 re-loadings without failure. The reason for this is that the case of a rifle-cartridge costs 1½ cents, while the complete cartridge costs only 2½c., thus it is good economy to re-load as often as possible. In making a case, flat discs are stamped out of brass sheets of the requisite thickness. The next operation cups the disc, and by a series of these it is formed into a cylinder, 'necked-down' to the shape required, and the head is finally formed from the thick metal left in the base. After each operation the brass must be annealed, as the working makes it hard and it would crack on further working. Both the copper and spelter must be pure, as impurities make the brass hard and cause it to crack. Good electrolytic copper is pure enough, but the spelter must be purer than ordinary brands, which contain too much lead for this purpose. Spelter made from the franklinite and zincite ores of New Jersey and the blende from Tennessee, which are free from lead, therefore commands a premium over prime Western. This premium has recently been large enough to warrant the re-distilling of ordinary spelter in order to purify it. Another reason for using brass of the highest quality should be pointed out. Brass is used for cartridges rather than copper because the cases must possess sufficient resilience to spring away from the sides of the gun-chamber, after firing; otherwise the shell cannot be extracted, and the gun is temporarily out of commission. This is especially important in the case of quick-firing guns. If the case splits or cracks, it will stick in the chamber.

As previously stated, all cases are re-loaded. But it must be remembered that it is a long long way from Bukowina to the Naugatuck valley of Connecticut, while many shells are lost on the battlefields and will not find their way back for re-loading for a long time. Orders for ammunition are being based on immediate requirements; in the event of the War being protracted the rate of consumption will probably decline, and when peace is concluded enormous quantities of scrap brass will find their way into the markets of Europe. What effect this is likely to have on post-War copper consumption it is difficult to prophesy.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Speculation in Mining

The Editor:

Sir—Your excellent editorial on speculation in mining and Mr. Todd's article on 'Financing Mining Operations,' appearing in your issue of April 17, arrived just in time to be of great service to me in the preparation of a paper on 'Speculation in Mining Stocks' upon which I was then at work and which was read at the regular meeting of the Spokane Mining Men's Club, on April 29, in view of the increased activity in mining.

So fully did your ideas, and those of Mr. Todd, accord with my own that I found it very advantageous to quote, *verbatim,* entire paragraphs from your articles, thereby greatly strengthening my own definitions and arguments.

Always such articles as these are in order; even if they often fail of their intent they are justified as educational measures which the wise will heed if the foolish will not; like the danger signs on our speedways these financial warnings are old in themselves yet they are ever new to newcomers and invaluable aids to the cautious.

Assuredly, then, to try to lessen losses from fake promotions, and to show inexperienced mine-owners how best to organize their ventures so long as they persist in the error of acting on their own initiative, is not only well within the province of technical journals but is also a part of the duty of every organization of mining men that has the industry's welfare at heart.

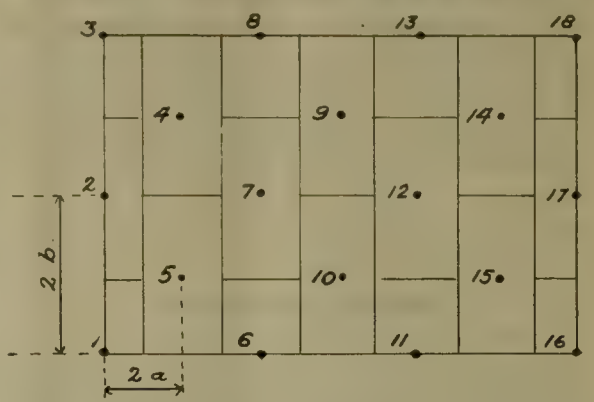
Spokane, May 15.

Valuation of Dredging Ground

The Editor:

Sir—I notice in your issue of December 19, 1914, a letter from J. T. Dixon on this subject. Mr. Dixon's method is analogous to the method in general use for the calculation of ore reserves. The average depth of a tract of ground corresponds to the average stoping-width; the value per cubic yard to the value per ton over the stoping-width; the volume at each hole to the tons in each block; and finally the total cubic yards at so many cents per cubic yard over an average depth to the total tonnage at so many pennyweights per ton over a certain stoping width.

Mr. Dixon states the average value is the total value divided by the cubic contents of the ground in question, and in order to arrive at the cubic contents assumes that the distance between the lines of holes is $2a$ and between the holes is $2b$. Further, referring to hole No. 1, the area to be included in the calculation is ab, the volume



is $40ab$ and the value contained therein $5200ab$. By similar calculations the following results are obtained:

	Area.	Feet.	Volume.	Cents.	Value.
1	$a \times b$	$\times 40 =$	$40ab$	$\times 130 =$	$5{,}200ab$
2	$a \times 2b$	$\times 30 =$	$60ab$	$\times 35 =$	$2{,}100ab$
3	$a \times b$	$\times 20 =$	$20ab$	$\times 60 =$	$1{,}200ab$
4	$2a \times 2b$	$\times 20 =$	$80ab$	$\times 50 =$	$4{,}000ab$
5	$2a \times 2b$	$\times 20 =$	$80ab$	$\times 40 =$	$3{,}200ab$
6	$2a \times b$	$\times 30 =$	$60ab$	$\times 50 =$	$3{,}000ab$
7	$2a \times 2b$	$\times 20 =$	$80ab$	$\times 160 =$	$12{,}800ab$
8	$2a \times b$	$\times 30 =$	$60ab$	$\times 42 =$	$2{,}520ab$
9	$2a \times 2b$	$\times 25 =$	$100ab$	$\times 25 =$	$2{,}500ab$
10	$2a \times 2b$	$\times 25 =$	$100ab$	$\times 20 =$	$2{,}000ab$
11	$2a \times b$	$\times 35 =$	$70ab$	$\times 8 =$	$560ab$
12	$2a \times 2b$	$\times 35 =$	$140ab$	$\times 10 =$	$1{,}400ab$
13	$2a \times b$	$\times 30 =$	$60ab$	$\times 15 =$	$900ab$
14	$2a \times 2b$	$\times 25 =$	$100ab$	$\times 12 =$	$1{,}200ab$
15	$2a \times 2b$	$\times 30 =$	$120ab$	$\times 10 =$	$1{,}200ab$
16	$a \times b$	$\times 30 =$	$30ab$	$\times 10 =$	$300ab$
17	$a \times 2b$	$\times 32 =$	$64ab$	$\times 12 =$	$768ab$
18	$a \times b$	$\times 25 =$	$25ab$	$\times 9 =$	$225ab$
Total	$48ab$		$1{,}289ab$		$45{,}073ab$

At this point the method is rendered much simpler by deleting the remainder of Mr. Dixon's procedure and simply finding the total volume (necessary in any case in order to obtain the cubic contents). This volume, as indicated above, is $1289ab$. Dividing the total value, $45{,}073ab$, by the total volume, $1289\ ab$, the result is 34.967 cents per cubic yard, since the value at each hole is given in cents per cubic yard. If the average depth of the tract of ground is desired, then dividing $1289ab$ by $48ab$ the result is 26.854 feet. The reason that the results are the same whether taking the lines of boreholes

vertically, horizontally, or diagonally across the diagram is simply because the area at each hole remains the same in each case.

Liverpool, March 25.

Florence Zinc

The Editor:

Sir—On page 733 of your issue of May 8, 1915, the following appears: "Florence oxide is the name applied to oxide of zinc made by the French process. The best known of these products are produced by the Vieille Montagne." This is not entirely correct. Florence zinc is the brand applied to the oxides of zinc made by the French process by the New Jersey Zinc company. The Vieille Montagne company makes French-process zinc, but its product is not known as the Florence brand. The best known French-process oxide of zinc in this country is the Florence brand, which unquestionably equals and is superior to most of the imported French-process oxides.

H. G. Clopper.

New York, May 13.

Flotation of Copper Ores

The Editor:

Sir—The mention of my name in your recent article on this subject tempts me to offer a few remarks that may be of general interest.

Pneumatic flotation is already fully established in a number of places and the results in comparison with the other and older schemes fully justify the opinion of your correspondent that it constitutes the most distinct advance in flotation in recent years.

The first pneumatic flotation plant in this country was erected by me in February 1914 for the National Copper Company at Mullan, Idaho, a description of which has already been published. The results were fully up to expectations from the very start. This plant consists of 8 rougher and 2 cleaner cells and treated 500 tons per 24 hours. A 30-hp. motor furnished power for all the air necessary for both mixing and separating, and the oil consumption averaged as low as 0.13 lb. of refined pine-oil per ton of ore. It was an ideal floating ore. Since then the Callow scheme has been adapted by nearly all the other mills in the Coeur d'Alene for the treatment of their lead-zinc fine sand and slime-feed, and has been a means of simplifying their plants and adding greatly to their recoveries.

The other plants that I have since erected have followed the same general lines as were laid down at the National, namely, air or tube-mill mixing and emulsifying of the feed followed by the separatory cells run in parallel. Recent results at the Inspiration mine would indicate some advantage (on that ore, at least) in running the cells in series of two instead of parallel, and without any sacrifice in capacity for a certain set number of cells. On an ore carrying a large percentage of mineral there is not much doubt that the series plan will give the best results and possibly dispense with the necessity of cleaning the concentrate.

The various elements that compose the scheme in general are illustrated in the accompanying diagram. The preparation of the pulp by any form of violent or propeller agitation is not necessary for good results with the pneumatic process. Where the oil can be introduced into the tube-mill no further refinement in mixing is necessary. This, of course, cannot always be done and in such cases air-mixing with the Pachuca becomes necessary.

A standard separatory cell has a capacity that will vary from 35 to 75 tons of feed per 24 hours when run in parallel, depending of course upon the characteristics of the feed. Two cells in parallel will have about the same capacity as two cells in series, but a slightly lower tailing may be expected with the series treatment.

The porous medium in the bottom of the cell is a loosely woven canvas-twill four layers thick, secured to the upper surface of a perforated plate with bifurcated rivets and washers. This is the present standard construction and has been adopted after a great many disappointing experiments with other materials. It is good for a three or four months' continuous campaign, and becomes inoperative only through the filling up of the pores by dust that has been introduced by way of the blower. Four or five pounds of air-pressure is ample in all cases to give the proper aeration, the quantity of air varying from 6 to 10 cu. ft. per square foot of blanket-surface. When the cell is properly adjusted and doing its best work there should be no violent agitation within the cell, but only such agitation as is incident to proper aeration. Any violent agitation producing a surging of the liquid contents has proved detrimental to good results.

A slope of 3 in. per foot on the bottom has been found sufficient to treat all ordinary ores after crushing through 30 or 40-mesh. Treating coarser material or ores that contain a large percentage of heavy gangue (such as in the Coeur d'Alene), it has been found advantageous to increase this to as much as 4½ in. per foot to prevent the blanketing of the porous medium by coarse sand collecting on the bottom.

The air from the separatory cells has so far been furnished from positive blowers, but turbine-blowers would be preferable where the size of the installation justifies their adoption. An air-pressure of 15 lb. is ample for the Pachuca mixer and 25 cu. ft. of free air per minute is sufficient volume for mixing 250 tons of *minus* 48-mesh pulp, and of course should be furnished from a low-pressure compressor.

The density of the pulp may vary from 2½:1 on a sandy feed up to 7:1 on a strictly slime-feed. The particular density is not a matter of so much importance as that the supply of pulp shall be uniform as to its density, since each variation in the density requires a readjustment of the oil-supply, the quantity of oil required increasing in proportion to the increased volume of the pulp independent of its solid content.

The advantages of the pneumatic scheme are greater recoveries, less oil, greater simplicity, and less skill required to operate. The difference in wear and tear is obvious.

Proof of the increased recoveries is shown in Table I, which represents a 30-day competition. It is noticeable that this increase in recovery lies principally in the finer and slime portions of the feed.

TABLE I

ANALYSIS OF TAILING—THIRTY-DAY PERIOD

Mesh.	Weight.	Total copper. Flotation tailing. A.P.	Flotation tailing. P.P.	Table tailing. A.P.	Table tailing. P.P.	Copper oxide in combined tailings.
	%	%	%	%	%	%
+ 65	7.0	0.38	0.37	0.30	0.29	0.13
+ 100	15.0	0.43	0.44	0.29	0.24	0.13
+ 150	12.0	0.44	0.50	0.30	0.25	0.16
+ 200	9.8	0.54	0.44	0.34	0.26	0.22
— 200	56.2	0.58	0.42	0.56	0.43	0.33
Average for all sizes.	100.0	...	...	0.44	0.35	...

TABLE II

ANALYSIS OF CONCENTRATES

For the same period

	Cu, %	Insol., %	Fe, %	S, %
Agitating process	32.34	26.50	15.01	22.79
Pneumatic process	31.24	23.70	16.79	23.84

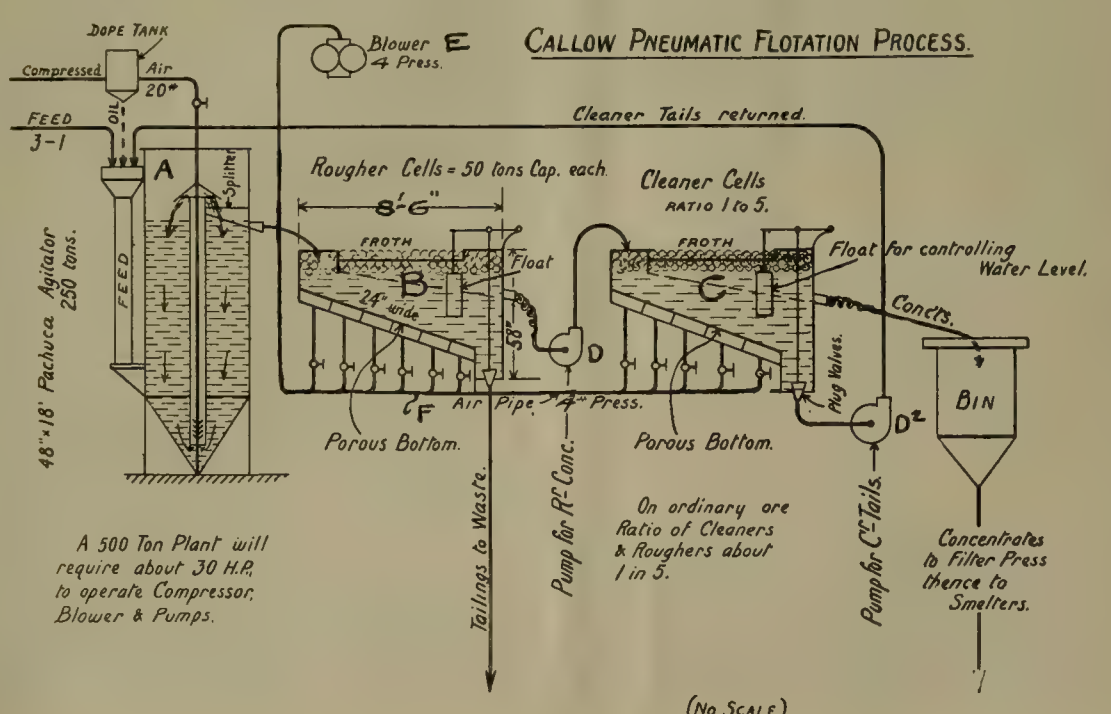
The resulting concentrates from the same competition are shown in Table II, which indicates that the slightly lower grade of copper is more than offset by the lower insoluble and higher iron contents.

The proof of lower power consumption is that the 10 cells of the National Copper Co. were run with a 30-hp. motor and treated 500 tons per day, the same tonnage treated by a propeller machine would have taken close on to 100 hp. This figure has also been confirmed at other places. The power required will vary from 2 to 3 kw.-hours per ton.

The froth produced from the pneumatic process is much more ephemeral than that produced by propeller-agitation machines, a self-evident advantage when it comes to collecting and handling the resulting concentrates.

Regarding oils, the remarks of your contributor with regard to cresylic acid and the methods of analysis given are extremely interesting and valuable. So far as my own experience goes, I have not found cresylic acid indispensable; at the present time and price it is out of the question as a flotation agent; it would seem, moreover, that the same results can be obtained by the use of less refined and expensive reagents. In the Coeur d'Alene on the zinc-lead ores, wood creosote seems to give the best results. The Inspiration uses a mixture of 80% El Paso coal-tar and 20% creosote. At one time we used a 2½ to 5% addition of pine-oil, but this has since been found unnecessary. A mixture of 20% pine-oil, 20% cresol, and 60% carbolic was tried experimentally at the Miami mine, but just as good results were obtained by substituting Salt Lake creosote for the cresol and carbolic. These are both chalcocite ores with some pyrite; the chalcocite is easier to float than the pyrite. The pulp is neutral. The recoveries will approximate 95% of the sulphide-copper contents.

I have tried a great many of the wood-oils, both the



steam-distilled refined products and also the destructively distilled crude tars and creosotes, but have generally come back to the coal-tar mixtures. The pine-tar products are excellent frothers but the coal-tar products seem to act as collectors and a combination of the two is often necessary. Acid sludge has been used with good success on Butte copper ores, but the disadvantages of this are that it requires heat and also additional quantities of acid to get the best results. This means working with an acid pulp and prevents the introduction of the oil into the crushing mill because of the destructive effect of the acid on anything but a silex-lined mill. Some ores work best in an alkaline pulp and others in a neutral one. My own opinion is that in most cases the same results can be obtained in alkaline or neutral pulp as can be obtained in an acid one and the advantage of an alkaline or neutral pulp is self-evident.

In one plant we had an interesting experience of this kind. The water-supply was limited and all the milling-water was returned back to the mill. The flotation results gradually deteriorated as the mill-water accumulated acid; the more acid it got, the poorer the results. Lime was then added in the tube-mill and the pulp made alkaline; this produced a tremendous increase in the volume of froth made, but without any definite improvement in the tailing. By reducing the lime and allowing the pulp to work back to the neutral point the results again became normal; and it is at the neutral point that we now do our best work.

There is a great deal of work yet to be done with oils, especially in compounding, modifying, and in making them miscible without heat. The right combination of oil is everything; the quantity per ton has less influence on the results than the right mixture. The effect with too much oil is mechanical rather than metallurgical; too much oil produces so much froth that it overflows everything and cannot be handled in the plant. Some experiments made in this direction gave the following results:

Oil per ton, lb.	Grade of concentrate, %	Extraction, %
2	15.55	90.08
30	9.82	95.91
100	7.95	93.46

But this is a large subject and altogether beyond the scope of these random remarks.

J. M. Callow.

Salt Lake City, April 23.

A Correction

The Editor:

Sir—In your issue of May 15, page 766, the following statement is made: "Silver sulphide only, and no metallic silver, is formed by the reaction between cupric sulphide and silver nitrate, the equation for this reaction being $CuS + 4AgNO_3 = Ag_2S + 2Ag + 2Cu(NO_3)_2$."

This equation, to begin with, flatly contradicts the statement "no metallic silver." Also the equation is itself false, as it shows one Cu atom in first member, and two in second. Probably the real equation would be: $CuS + 2AgNO_3 = Ag_2S + Cu(NO_3)_2$. This, at all events, is consistent, and also verifies the assertion of "no metallic silver."

Regis Chauvenet.

Denver, May 19.

[We are glad attention has been called to this error, which arose from a mistake in copying. The equation as given by Mr. Chauvenet is the correct one. The second half of the equation given above is the product of the reaction between silver nitrate and cuprous sulphide.—Editor.]

Amalgamation in Hardinge Mills

The Editor:

Sir—R. B. T. Kiliani, who has given you an account of results obtained with Hardinge mills at the mill of the Incaoro Mines Company, in Bolivia, must have obtained his information from some one who did not know how we do things here. I have been here for three years, or since the company started work, and for the benefit of those interested I will record the results actually obtained. When we started the plant we lined the pebble-mill with silex brick, which was a failure. Hard granite was then tried, for want of better material; it lasted but a short time. Flint pebbles of 6-in. diameter are now being used with good results. These are set in cement. For grinding purposes, instead of flint pebbles, lumps of hard quartz from the mine, rounded up a little with a hammer on the sharp edges and weighing 2 to 3 lb., are used. These work just as well as flint pebbles and are much cheaper. The neck-piece that connects the feeder to the ball-mill was too short and caught pieces of quartz between the feeder and the feed-box. One made 6 in. longer works well. The mill crushes but 60 tons per 24 hours. Mercury is fed into the ball-mill every hour. This leads to a small loss from 'flouring' inside the mill, but it has proved the best method. We clean-up every 15 days, and the amalgam is found distributed from the ball-mill to the pebble-mill. Large pieces of amalgam collect around the door of the pebble-mill, but no loose balls of amalgam are found inside the mills. Three-quarters of the amalgam is collected from inside the mills and one-quarter on the plates. The amalgam contains 40% gold before retorting. Our gold runs 900 fine; we ship it to New York. I used to think that a stamp-mill was the best mill made, but I have changed my mind. We find it very hard to keep mill-men here, as the altitude is 14,000 ft. above sea-level. We very often have to break in some of the natives to run our plant, which would be difficult to do if we had a stamp-mill.

George R. Pringle.

Sorata, Bolivia, April 20.

[Mr. Pringle's letter is welcome. The longevity of the stamp-mill astonishes even its friends. We expect many important changes in milling practice to come about as a consequence of the development of flotation and leaching. —Editor.]

Goldfield Re-visited—II

By T. A. RICKARD

On the occasion of my former visit, in April 1908, the richest ore from the mines of the district was being sent to the smelters near Salt Lake and San Francisco, while the lower-grade ore was subjected to amalgamation, cyanidation, and chlorination. Now amalgamation and chlorination have been displaced; cyanidation alone survives. At that time the Goldfield Consolidated company had just begun the erection of its big mill. F. L. Bosqui, as consulting metallurgist, expected to make an extraction of 95% by cyanidation at a total cost of "under $2.50" per ton. The mill did achieve an extraction of 95.4% at a cost of $1.60 per ton. This does great credit to J. W. Hutchinson, who was mill superintendent until he became general manager for the Goldfield Consolidated Mines Company in January last. His detailed description of the mill appeared in successive issues of the *Mining and Scientific Press* during May and June 1911.

MAIN STREET OF GOLDFIELD.

On entering the mill the rhythmical noise of the stamps sounded to me like familiar music. The 100 stamps crush 1015 tons per day in cyanide solution through 4-mesh screens. The circulating solution contains 0.4 lb. cyanide per ton. Crushing in solution saves cyanide, but it decreases the extraction of gold in sulphide ores. The advantage, however, exceeds the disadvantage. There is also a saving of water, which, at Goldfield, costs 50 cents per 1000 gallons. The extraction made by the mill is now 92%; it has been higher. The percentage could be increased, but to do so would not be economical, for the expense would exceed the monetary gain.

The first observation to be made inside the building is the tremendous foaming of the pulp as it passes through the different machines, culminating in a vast mess of bubbles in the dewatering vats. This is due to the reaction between the lime and the sulphates in the ore. When the mill started, only 8 lb. lime per ton was required to neutralize the acidity of the ore; when the roasted concentrate was treated the addition increased to 11 lb. per ton; now it is 20 lb., this final increase being due to the treatment of caved ground, remnants, and dump, all of which contains the sulphates produced from the oxidation of the pyrite and chalcopyrite. Most of the lime is added to the ore as it passes through the first gyratory crusher, the lime being fed by a traveling belt moving 2 ft. per minute. Further rectification is made in the mill, by adding an emulsion or milk of lime.

One of the few defects of the plant is seen in the crusher-house, where there is insufficient room for screening between the bins and the first crusher, a Gates gyratory. There is also lack of grade between the trommel below the first gyratory and the two secondary crushers. Another apparent defect may be mentioned here, namely, the harnessing of three tube-mills to one motor; each might be operated separately or at least not more than two should be placed on a single drive, with ability to cut out one tube-mill when convenient. On the other hand, by the existing arrangement the high starting-torque required for tube-mill operation, necessitating 40 hp. extra, is distributed over three mills.

Since the mill was constructed the only modification in the design has been the elimination of the 36 Deister tables for the treatment of middling, this change being due to the milling of lower-grade ore. At present 60 Deister tables (of the No. 3 size) are in use. On asking the manager if they were doing good work, he replied "Excellent." On the white rubber covering of the Deister tables one can see the free gold clearly, for it forms a yellow rim just above the pyrite. Another minor change is the increase in the number of leaves in the Butters vacuum-filters; 386 are in use as against 336 formerly; two boxes, containing 50 leaves, having been added.

The high price of spelter is not without interest to the superintendent, for the mill requires 425 lb. of zinc-dust per day, or about 6 tons per month.

The concentrate averages 6% by weight of the ore milled and contains 67% of its valuable contents. Formerly this product was treated with acid wash, bromo-cyanide and peroxide; later this method gave way to a preliminary treatment with alkaline cyanide, which extracted 85% of the gold, leaving a comparatively low-

grade product to be roasted. Thus the loss in roasting was minimized. Now the raw concentrate, which has decreased in assay-value from about $200 to $30 per ton, is sent direct to the roasting-furnace.*

The daily output of concentrate is 80 tons, containing 18% sulphur. This is roasted in two Edwards duplex furnaces (112 by 13 ft.) having 54 spindles (or rabbles arranged in two rows for each furnace. The fuel used is crude oil, 14°B., from Bakersfield, California. Nine gallons of oil is required per ton of concentrate. Contact with the heat is maintained for 10 hours. It is found necessary to fire only at the feeding end, the fineness of the material facilitating the advance of combustion so as to obviate the need for firing at the finishing end of the furnace. The roasted product is wetted as it leaves the furnace, the resulting pulp flowing to a series of 5 air-lifts giving a total lift of 45 ft. to the collecting-vats, where the pulp is dewatered to a consistence of 1:1. Then 10 lb. of sulphuric acid per ton of dry concentrate is added. Agitation is maintained for 8 hours, with subsequent water-washing, for recovering the copper and eliminating the sulphates. All the washes and decantations are passed over scrap-iron for the precipitation of the copper. The recovery of copper is at the rate of 3 lb. per ton of concentrate. This pays for the acid treatment.

Meanwhile the pulp, freed of its copper, is neutralized with lime and delivered by a centrifugal pump to one of two Pachuca agitators, where the dissolution of the gold is accomplished. When completed, the residue is delivered to storage-tanks in the mill proper; there it is filtered, and finally sent to waste with the mill-tailing. The solution goes to a separate circuit and precipitates its gold on zinc-dust. The total cost of treating the concentrate is 90 cents per ton.

Outside the mill a couple of imposing steel structures command attention; these are the dominant portions of a plant for returning the tailing to the mill for re-treatment. The tailing has been carefully impounded; it covers about 100 acres, and weighs 2,000,000 tons, averaging $1.60 per ton. To treat this residue the company has erected a Lidgerwood radial aerial cable-way with two stationary revolving towers and a traveling car. The towers are 160 ft. and 125 ft. high respectively. The lower tower moves in the arc of a circle along a standard-gauge track, having 135-lb. rail. The two tracks are 70 ft. apart, centre to centre. The rope is of 2¾-inch diameter. The capacity of the machine is 500 tons in 8 hours and the cost of it to date is $91,600. The expense of returning the tailing to the mill is estimated at 6 cents per ton.

A visit to this mill leaves a strong impression of the skill shown in its original design and an appreciation of the fact that it has accomplished its purpose most effectively. From the day the mill started (December 26, 1908 to the end of 1914, the mine has produced 1,895,338 tons of ore yielding $43,710,665. The only regret is the apparent termination of its useful activities, for the Goldfield Consolidated mine cannot continue to furnish sufficient ore for long, and no other mine in the vicinity shows any prospect of yielding a supply adequate for so large a plant.

In 1908 one of the principal technical operations in the district was 'high-grading,' a polite term for the theft of ore by the miners, who took their spoil to the 'fences' or assay-offices, where it was bought and reduced to bullion. During the summer of 1907 fully $1,000,000 worth of ore was thus stolen from the Mohawk and Combination mines. It is said that at one time 36 so-called assay-offices were running all night, some of them miniature smelters, and all brightly illuminated by electric light. That was the time of the Frances Mohawk and Hayes & Monette leases, when, in the summer of 1906, Goldfield seemed to sweat gold. In the Frances Mohawk lease at a depth of 200 ft. there was an 8-inch vein that assayed $250,000 per ton, mostly free gold and the telluride of gold (calaverite). The various leases on the Mohawk mine yielded a total of $50,000 per day for 106 consecutive days. When the principal lease was about to terminate, the lessees paid the miners $10 for 8, or even 6, hours of labor. No discipline was maintained, for a refusal to work would have prevented the lessees from gathering their golden harvest before the expiration of the lease. The miners came from underground with their jeans and jumpers stuffed with specimen ore. The worst element in the Western Federation of Miners was in control of the labor supply and the rights of property were treated humorously. Then came the big strike (not of ore, but of miners) in the fall of 1906. Troops under General Funston (recently at Vera Cruz) paraded through Goldfield and a bloody conflict was only just avoided, thanks to the respect felt for the regulars. When a committee of citizens paid a call on the General, he remarked that he had never seen so many overcoats on a hot day. All of them were armed with revolvers and sawed-off shot-guns. Every building had gun-men on its roof. On the Montezuma club, the headquarters of the mine operators, there were 15 such sentinels on the alert for trouble. Everybody expected the town to 'go up' any minute. It was like living on the edge of a volcano or the rim of a copper converter. Thus I return to my metallurgical simile.

Journalism also had its romance amid this explosive environment. Charles S. Sprague, recently identified with the Jumbo Extension mine, had formerly owned the Colorado Springs *Daily Telegraph;* at the height of the Cripple Creek boom he sold it for $65,000 and drifted to Goldfield. Arriving there he was engaged as editor of the *Tribune*, at $75 per month and one-third interest. The boom was in full swing. The only unpaid matter appearing in the paper was a 'stick'—about two inches—on the first page; all the rest of the reading matter was inserted for 60 cents per line, paid by promoters and brokers. Not every promoter was a broker, but every broker was a promoter. The 'mining game' was *in ex-*

*A description of the treatment as conducted in 1912 was written by J. W. Hutchinson for the *Mining and Scientific Press* in the issue of January 25 and February 1, 1913.

cents. Yes, those were glorious days. When a deputation of citizens went to Carson City, to persuade the legislature that Goldfield was particularly fitted by man and nature to be the county seat, the gentlemen from Goldfield began to throw nickels among the boys and ended by chucking $20-pieces. Having succeeded in their enterprise, they invited the legislators and their families to visit Goldfield; they chartered a train of pullmans for their guests and on their arrival in the golden city they ladled champagne from wash-tubs, because, of course, it takes time to pull corks.

Yes, those were the good old days. It seems long ago, but it was only yesterday. Among the more pleasant stories I like to recall that of Smith and Benedict, two stock-commission men from Chicago, who in 1906 had placed his money in stable investments. The discoverer of Goldfield, Harry Stimler, is running a mine at Goldfield. When he located the Sandstorm and started Goldfield on its bullionic career, he was working under a grubstake from Jim Butler, the discoverer of Tonopah. It will be remembered that Tonopah was the parent of Goldfield, the one being discovered in August 1900 and the other in December 1902. After Jim Butler had made some money, his wife persuaded him to buy a ranch at Bishop, in Inyo county, California, where he now lives comfortably. Finally, T. L. Oddie, who took a prominent and intelligent part in these discoveries, became one of the owners of the Tonopah mine and was elected Governor of Nevada, for the four years from 1910 to 1914. He is now operating at Willard, near

THE MOHAWK MINE, GOLDFIELD.

bought into a lease near the Sandstorm. They came to look at their mine, but the shaft had caved, owing to faulty methods, so they spent a night gambling with some of their acquaintances. During the evening they agreed to pay $10,000 for a half-interest in the Hayes & Monette lease. Leaving next day, they went to San Francisco and Portland, with an uneasy feeling of uncertainty as to what they had done. Not being clear about it, they telegraphed to Hayes and Monette to meet them at Reno and paid the $10,000 in cash. They were anxious to carry out their agreement as honorable men, even if they had a hazy recollection of the reasons prompting the deal. They had a code of their own. Soon after, Hayes and Monette wanted $10,000 more to develop the mine. Smith and Benedict returned to Chicago and tried to dispose of their interest, at the very moment when rich ore had been struck in the lease. They failed in their effort to sell and were forced into a fortune. Each of them made over a million dollars. Of the others, Mr. Monette is now a big banker at Los Angeles, while Mr. Hayes retired from business and Lovelock, the new district recently named after the champion pugilist. It is a dangerous baptism: champions have their day. We hope Willard may outlive its namesake.

When purchasing new equipment many firms specify something like the following: All angular moving parts or projections must be avoided so far as possible. If impossible to avoid their use, all gears, cams, eccentrics, setscrews, bolts, sprockets, chains, belts, feathers, splines, keyways, cranks, connecting rods, or other dangerous revolving or moving parts actuated by power, must be so guarded and protected as to render contact, intentional or otherwise, between them and the person or clothing of the attendant as nearly impossible as the work to be performed will permit. All guards must be so constructed and built up as to be readily removable without the use of special tools, allowing ready access to the working parts. It must be the aim of the builder to produce a machine that shall be as safe to handle and operate as human ingenuity can devise.

Notes From South America

By MARK R. LAMB

When the London metal-markets were paralyzed, the copper and silver mines of Chile suffered the same fate. Now that the price of copper is good, every copper miner is trying to get another start, but lack of ships to carry his ores and bars, and high freight-rates combine to hold him back. Even such ships as have contracts are accepting 20 tons when 100 are offered. Besides the ships sunk and withdrawn as transports, and those interned, others have been taken from this coast run to ply between New York and Europe at the high rates prevailing.

The copper smelters are running as slowly as possible in order to make their supplies of coke last as long as they can. Coke has now reached a prohibitive price, as none is coming from England or Australia, and American coke manufacturers have not yet found the market.

There have been violent fluctuations in the exchange-value of the Chilean peso lately, and as gold mining here is dependent for its highest profits upon a low exchange-rate, the gold miner is joining hands with the agriculturist to force exchange down.

The retrenchment and economizing forced on the country by the curtailment of export of nitrate is an important factor in the raising of the rate of exchange. It is freely prophesied that the peso, which is now worth 8 pence, will go to 18 pence (par) if the War continues much longer. Personally, I want the peso to increase in value so that my customers can buy more and to decrease in value so that my salary will go farther.

The economic point of view in Chile is changing rapidly. Formerly it was necessary to have an automobile, or at least a fine carriage and pair. Now it is absolutely the fashion to talk of straightened finances, and it is a lucky salesman who can find anyone even interested in automobiles.

Formerly there was no propaganda in favor of home industries, now the leading men of the country take pride in wearing Chilean cloth, which is like any other cloth and is at the same time pure wool and cheaper.

Wages for the laborer fell seriously at the "drop of the hat," this being an important saving for the mining companies, but hard on the laborer.

A reasonable freight-rate to the States would start a mining boom. Of course, the copper miners know that the price of copper is high because the production in the States is curtailed, but they also know that the production in Chile is comparatively small and therefore will not effect the world's market-price. If there were only a few American ships!

It is announced that Chuquicamata will be formally started on May 15 by his excellency, Don Ramon Luco, President of Chile, who will press the button in the capital at Santiago. It is expected that the plant will be running nicely in 30 days thereafter, and the ultimate capacity of this unit is quoted as 600,000 lb. of copper daily. The average man has difficulty in grasping these figures and wonders where such a quantity of copper can be absorbed.

With the present price of quicksilver there has been an increased interest in the two extensive deposits of cinnabar north of Santiago, near Ovalle, and if the price holds up long enough to make a proper start, the owners will make money. One engineer is getting together several small lots of quicksilver from old amalgamation plants in Chile, Bolivia, and Peru, and expects to ship a few tons to the States.

Three small gold mines are producing at present. The Miles mine of Sr. Felipe Herrera, near Ovalle, produces 8 ounces of gold daily with a Tremain stamp, and the Las Vacas mill, with 10 gravity stamps and a cyanide plant, is averaging 15 oz. fine gold. Don Luís Charme, of Santiago, has a Tremain on order to reduce 800 tons of hand-sorted gold ore.

Condoriaco is not operating, on account of differences between the lessees and the owners. The ore can be

COPPER READY FOR SHIPMENT FROM CHILE.

sorted to a high-grade in gold and silver. The highest grade was shipped and the lowest grade treated by stamping, concentration, and cyaniding.

The French company operating copper smelters at Naltagua and Catemu has lately lined its small acid converters with basic brick. In spite of the very small size of the converters, the manager, Mr. Lehmann, is getting excellent results and is making a big saving in cost, as compared with previous practice.

GOLD RECOVERY on the Rand has increased from 60% in 1890 to a maximum of 96% in 1914. The chief contributing factors were: introduction of slime treatment in 1894, advent of the tube-mill in 1904, improvements in classification from 1907 to 1910, and the vacuum-filter in 1909. At the same time a large number of mechanical and metallurgical details have helped the better recovery. The cost decreased during that period. At the Modder B. the total charge from the crusher to the residue dump is only 68.6c. per ton milled.

BLADES in impulse steam-turbines occasionally work loose and drop out, or are knocked out by some means. The single-stage machine revolves at a high speed, and when blades are lost vibrations are set up in the shaft. These wheels must be perfectly balanced, the loss of a single blade causing noticeable shaft vibrations.

Technical Reminiscences—II

By ALBERT R. LEDOUX

Not many years after the opening of our laboratory in New York City, in 1880, our growing business made it advisable to establish a sampling-plant for ores and metals at the port of New York. We had been doing the best we could by handling shipments on the railroad-docks and by carting bars to be drilled at various machine-shops. The important question was where to erect this plant.

At that time there was a freight pool with headquarters at Chicago. Shippers of ore and other products could not control the routing, the pool dividing the freight arbitrarily between several lines, regardless of the conditions stipulated in the original bill of lading. The receivers of the material at this end, whether they were smelters or exporters, did not care over what line the material came east, as all the bills of lading called for free lighterage within the limits of the port of New York. We made careful inquiry of each railroad, as to whether it would be interested in helping us to secure this east-bound freight for its line, should we select a site alongside. The representative of the New York Central said the matter did not interest them in the least. The Pennsylvania Railroad people were most courteous and offered us a site on the Jersey meadows, at a fair rental, and agreed to stop all cars the contents of which we were to sample. The Erie Railroad exhibited such extraordinary liberality and such a grasp of possibilities that we decided to take our chance with them. They instructed their real-estate agent to go with me and look over all the land they had in and near Jersey City, and said that I might take my choice of a site. I selected an unoccupied building that they owned upon their line back of Jersey City. It was equipped with an engine and boiler, and could be made over into a sampling-works without much expense; but when I reported my decision to Mr. George H. Valliant, of the Erie, he said: "I would not advise you to locate at that point because it is not accessible to any railroad except our own. There is a better site just outside of the Erie tunnel, within a stone's throw of the Lackawanna and of a branch of the Pennsylvania. We propose to treat you fairly, but if at some future time some other administration succeeding the present determines to take advantage of you, you would then be sufficiently near to these other roads either to run in short switches or to cart material." They therefore gave us a lease of this tract at the nominal rental of $10 per annum.

At that time, they were re-building their railroad station in Jersey City. They presented us with all the timbers coming out of the old structure that we could use, and ordered their boss carpenters to erect our building with the railroad's own labor, charging us only for the actual time of supervision and wages; so our building cost us very much less than had we built it entirely from lumber purchased and paid a contractor's profit.

In the lease, the railroad bound itself to stop all cars coming over its line, when notified that we wished to sample the contents, and agreed to send empty cars for the material when it was ready to proceed to the docks for lighterage. Furthermore, when I stated to them that in some cases the material might have to lie some time at our works, if it had been sent forward unsold or must await satisfactory freight arrangements for export to Europe, they added a clause to the lease placing no limit upon this detention of freight, if the cars were emptied and released. How this worked in one important case will be told later in this article.

As soon as we were established, shippers who had sold their product upon our sampling and assay, brought pressure upon the pool at Chicago to route over the Erie Railroad all products destined to be sampled by us in transit, compensating the other members of the pool, as far as possible, by giving them their equivalent in other freight. The result was that the Erie became the chief copper-carrier from Buffalo and Chicago to New York, not only of materials that we were to sample, but others; even Lake copper came chiefly over the Erie, because the agents of the pool got into the habit of considering the Erie *the* copper carrier, and did not always take the trouble to see whether my firm was to handle it all or not.

When the other railroads awoke to the fact that they were losing this copper freight, some of them made offers of large cash payments to us if we would change to their line on the expiration of our lease; but for thirty years our works were confined to the Erie, although we supplemented them by a plant on the Southern Pacific docks, where we could sample copper bars from Arizona or elsewhere in the Southwest, which come into New York by boat from Galveston or New Orleans.

A large part of the furnace material handled by us went abroad, and at first our certificates of sampling and assay in New York served only as a check on the final sampling in Europe, especially at Swansea. The sampling over there, while usually accurate, took a great deal of time, being done entirely by hand, not even crushers being employed, and the method of settlement was complicated in the extreme.

To begin with, the settlement sheets did not account for the product by the ton of 2000 pounds, nor yet by the ton of 2240 pounds, but by the units per so-called 'miners' ton' of 2352 pounds. There were charges for 'master porterage,' dock dues, town dues, and an arbi-

trary 'draft' of 3½ pounds was deducted from every hundredweight. Furthermore, there were many conventional charges and deductions from the settlement price; in addition, payment was made upon 'produce' by Cornish assay. This Cornish assay was an attempt to imitate the smelting process in the laboratory. The difference between the buyers and sellers—assuming that the British buyer re-sold to a smelter—were often great, and the two Cornish assayers 'agreed' upon the produce, for which the American shipper was ultimately paid, after delays of from 60 to 90 days. Nearly all the shippers endeavored to persuade the English buyers to accept American assays, but without result, until Mr. W. A. Clark sent to James Lewis & Son, of Liverpool, who were very anxious to get hold of 3000 tons of his matte, a cable that was epoch-making for the trade. He had offers here for his material, and said in his cable: "I will no longer submit to the robbery of English terms and conditions. I will sell for so much cash f.o.b. New York on Ledoux's certificate of weight and assay." James Lewis & Son had the courage to accept this proposition, and for the first time, probably, in the history of American ore or crude-metal exports, credit was opened in New York for the total payment, and Senator Clark received cash at so many cents per pound of fine copper contents against delivery to the New York bank of our certificates of weight, sampling, and assaying. The outcome when the matte arrived in Liverpool was satisfactory, and from that time on James Lewis & Son bought freely on those terms.*

I made a trip to Great Britain endeavoring to persuade some of the other British buyers to purchase on American assays. A meeting of the Swansea Smelters Association instructed their chairman, then Sir Hussey Vivian, later Lord Swansea, to say to me that they were perfectly satisfied with their method of doing business, which had not been changed for several hundred years, and that I need never expect any of the Swansea buyers to recognize American assays.

Later the Boltons, and some of the other smelters and refiners near Liverpool, followed the lead of James Lewis & Son, but Swansea was immovable. Then came an episode that changed the situation:

Billy McDermott, of Butte, sold to a New York firm 500 tons of rich copper ore and agreed to accept payment in New York on our sampling. The material went to Portland, Oregon, by train and came to New York by ship. We were obliged to sample it on the dock. McDermott came to New York to get his money. He had given the buyers an estimate of the copper contents of the shipment. We divided it into lots of 25 tons each, as nearly as possible, and sampled it by hand, reporting our assays as fast as completed. As soon as each lot was sampled, it was put on a tramp steamer, having been re-sold at Swansea. When we had reported most of our assays and had nearly finished the sampling, we were astonished to be served with an injunction, issued by a New York court, restraining us from completing the assays, ordering us to give into the custody of the Court the samples hitherto taken, and to show cause why this injunction should not be made permanent.

My lawyer inspected the affidavit upon which the injunction was granted, and I called on the people who made it. We found that they imagined that, either through negligence on the part of my firm, or through interference on the part of the seller, who had witnessed some of the sampling, the assays that we had reported were much higher than the contents of the ore.

Very soon after the service of the papers, a lawyer representing the buyers, who had obtained the injunction, called upon me and said that we would, of course, be paid for the assaying and sampling if we let the matter take its course, that our assays were really higher than the seller expected, and that they would settle in a way satisfactory to him; and that would end the matter. I referred him to our lawyer, and on behalf of his clients he offered our lawyer $500 to advise us to let the matter drift. Of course, these proposals were refused. Our capital was our reputation, and our reputation had been attacked in the affidavit. In the meantime, the material all reached the tramp steamer, which sailed for England.

I called upon the buyers with our lawyer, and informed them that I would push the case to the utmost legal limit; that I would make their action public, and confidently expected damages for this assault upon our integrity and upon our business. I made an alternative proposition, which was that we should send an expert assayer by fast steamer to Swansea; that when the material arrived, it should be sampled by methods satisfactory to us, and to be agreed upon by our representative and the sampler of the British buyers, and that a third assayer of prominence and not interested in smelting should be selected by the two assayers; that the sample should be assayed jointly by the electrolytic method of assay; that if the results showed there was material error in our New York sampling or assaying, whatever the cause, I would drop the matter and stand the expense; but if, on the other hand, the European sampling confirmed our own, the seller, Mr. McDermott, should receive pay on the American basis, and all our expenses in connection with the investigation should be paid by the buyers, who should acknowledge that their statements filed with the Court were erroneous. This was accepted; so we dispatched our chief assayer and sampler to Swansea to arrive before the cargo.

Fortunately for us, the controversy became public, and when the ore got there representatives from the smelters watched the work. They were entirely satisfied, and had explained to them the advantages of previous crushing, where possible, and of mechanical sampling.

The ore was divided between works at Liverpool, Swansea, and another place. The samples were assayed by the electrolytic method at the Royal School of Mines

*See 'Modern Copper Smelting,' by Edward D. Peters, 7th Edition, for difference in returns by electrolytic and Cornish assays.

by our representative, working jointly with one of the instructors in that institution. They were then assayed at the same place by our representative by the Cornish method, his work being directed and supervised by the authorities. Our representative then repeated the work in Cristoe's laboratory, both by the electrolytic and Cornish methods of assay. The results of the electrolytic determination confirmed our original assays in New York, whereas the Cornish assays showed about 1.3 units less. The American buyers paid our bills for expenses and services, admitting that our original assays had been correct; but the foreign smelters began to say to one another, "These Americans do know how to sample and assay." Shortly thereafter Sir Hussey Vivian himself signed a contract for a large tonnage of Anaconda matte to be paid for in New York on our sampling and the electrolytic assay less 1.30. This influenced German buyers competing for American products to make the same concession, after an independent investigation.

The custom of deducting 1.3 from the electrolytic or other wet assay seems to have originated in this country in very early days. It was prevalent at Baltimore as far back as 1872, but it had not obtained the sanction of trade custom in Great Britain, so far as I can learn, prior to the episode above described.

This gave us the beginning of almost a monopoly of sampling ore, matte, and copper bars for export, in spite of the fact that there were, as there still are, other laboratories in New York honorable, progressive, and equally experienced.

While we thus broke through the prejudices of Great Britain and Germany, we had as yet comparatively little business with the French. Our entry into that field came about by another one of the 'accidents' that —as stated in a previous article—have so markedly influenced my professional career. I was about to sail for Europe in 1887, when the active manager of a New York metal house, chiefly handling Swedish and other European irons and steels, called with a letter of introduction to Monsieur E. Secretan, the active head of the great French house, the Société des Métaux. This gentleman said they had been for some years the agents of that company in America; that Mr. Secretan had plans of some kind on foot which they did not as yet fully understand; and that he was asking questions about copper and American production which they could not always answer. He would be obliged if I would call upon Mr. Secretan in Paris with this letter of introduction, and give him such information as I might have.

I was exceedingly busy when in Paris and deferred my call until the day before I was to leave. Had Mr. Secretan been out, I would have left a note with an expression of regret at not finding him, and would have felt that I had performed my full duty. He happened to be in, and questioned me for over an hour on the product of the different American copper districts, on the qualities of the various brands on the American market, and wound up by saying that he was about to inaugurate a great change in the copper world; that Paris was to replace London as the arbiter of copper prices; that it would result in his having almost absolute control of nearly the entire American production; and that he had ample funds guaranteed to carry it through. He said that his present American agents were conservative and loyal, but that they had far more experience with iron and steel than they had with copper. To illustrate what he meant, he said that he had recently cabled for a price for a certain number of tons of copper, guaranteed equal to English 'best select.' His agents ascertained that 'best select' copper was a grade fit for the making of rolled brass; but the word "brass" alone had apparently impressed his agents, who had contracted with the Baltimore Copper Company for the shipment, under the solemn guarantee that the copper would "make brass." Assuming that the copper would be of 'best select' grade, Mr. Secretan had paid a high price for it, only to find that it was of a casting quality, but of course could be used in "making brass," though the product could not be rolled.

He urged me to take the agency of his company for America, and said he would guarantee me a far greater profit than I could possibly expect to make out of the business of consulting engineering, or sampling and running a laboratory. Of course, this was a great temptation, but my reply was that Mr. Secretan had overlooked one thing: that I owed the pleasure of his acquaintance to a letter of introduction from his present agents; that I could not possibly use this introduction as a means of supplanting them in the agency. This embarrassed Mr. Secretan very much. He assured me that he was going to change his agents anyway, and that if I did not take the agency, someone else would. I said that my mind was made up and that I could not discuss the matter further. He shrugged his shoulders and we parted.

The next evening but one I was called upon in London by the late Theodore Morrison, who said that he had been summoned by telegraph to meet Secretan—I think at Amiens; that they had talked half the night over the question of the American agency; that he, Morrison, while appreciating my sensitiveness, begged me to reconsider my declination, and said that possibly a little of my hesitation was due to a lack of full knowledge of the details of foreign business and international exchange; that he had a son who was in his office and who was thoroughly familiar with all these questions; that if I would accept the agency, he would place him in my New York office, and that I might feel entirely safe. I again declined to consider the proposition, although Morrison still further opened my eyes to the magnitude of the attempt which Secretan was making.

Not long after my return to New York, I was called upon by a representative of Secretan's agents, who told me quite frankly that Secretan had continued the agency with them upon the implied condition or expression of the wish that I should be retained to advise them in matters concerning which he or they might wish to con-

sult me; and that he had stipulated that in all the contracts where copper material, sold in or exported from New York, had to be sampled and assayed to arrive at its value, Ledoux & Company's assays and sampling should govern, and that payments would be made in New York, cash, against our certificates. Of course, I most gladly entered into this arrangement.

Copper mattes, ores, etc., began to pour into our sampling-works until we had to enlarge them and sometimes run them by night, and the business became really enormous—as long as it lasted. The world knows that Monsieur Secretan failed to carry through his great corner, largely because he had to purchase material from unexpected sources, and also because of the weakening of the financiers who were backing him.

Soon matte began to accumulate in our works; there were no shipping orders. We were instructed to hold it by representatives of the bankers who had made advances upon it. Seven thousand tons of matte was thus stored by us for seven years! We did not know who held our storage certificates, nor who owned the matte.

The corner having failed, the French government, which would have applauded Secretan had he succeeded in making Paris the chief market for copper instead of London, had put him in jail for restraint of trade, a director of one of the French banks that had financed him had committed suicide, and the owners of the copper matte did not dare show themselves.

At the end of seven years, our warehouse certificates were surrendered to us by a New York banker, covered with endorsements and transfers, and we were told to ship the matte to the order of Cassell's bank in London—and now comes in again the Erie railroad:

That matte had been delivered to us under the lease or working agreement by which the Erie was bound to deliver it to us for sampling and to send empty cars to transport it to its destination "when notified" by us. We simply sent to the Erie freight-agent the original arrival-notices endorsed with instructions to carry it to the docks and lighter it to the ocean steamers, and the original bill of lading contract was complied with by the Erie without any extra charge, although seven years had elapsed!

I met Secretan once more before his death, when I was sent to make a report upon the Elmore process as carried out at his works at Dives. He was a patriotic Frenchman in spite of his adversities, confidently believing that the world would have been benefited had he been able to carry through his ideas. He complained that not only had the heathen in China substituted copper-plated iron idols for their bronze gods, compelling him to buy the latter by the shipload, rather than to have this metal get into the hands of rivals; not only had many tramp steamers that had been carrying copper as ballast instead of pig-iron (which copper they had bought at 10c. per pound) unloaded it on him when it got up to 17c.; not only had thrifty housewives sold their old copper pots and pans; but that some of the largest producers of the world violated the spirit of their contracts with him. One of them, in particular, bound itself to limit its production, as did some others, by not 'raising' more than so many tons of ore during the term of the contract, but neglected to state that it had thousands of tons already 'raised' and on the dumps, which they rushed through furnaces the product of which he, Secretan, had to buy.

While, of course, some of the producers who sold to Secretan were friends of other assayers to whom they naturally would have given their business, yet the advantage of getting cash in New York was too great to be overlooked, and after the failure of the Secretan syndicate, many of the producers whose acquaintance and friendship we made at that time stayed with us.

Since those days the tides of commerce have changed. We handle little ore or matte or unrefined metals for export today, although the volume of Western American furnace material, flowing to the Atlantic seaboard for refining, goes largely abroad in refined forms, but the ends of the earth are sending their ores and furnace materials here, just now increased by over 50,000 tons of zinc ore from Australia.

American Smelting & Refining. The report for 1914 is notable on account of the following information given:

Men employed, excluding Mexico	12,179
Total wages and salaries paid, excluding Mexico	$10,212,591
Average wages per employee per 8-hour day	$2.33
Ore mined, tons	1,266,702
Coal mined, tons	257,942
Charge smelted, tons	4,171,258
Bullion refined, tons	588,718
Coke produced, tons	129,650
Coal used, tons	544,619
Coke used, tons	447,761
Oil used, barrels	976,528
Gas used, cubic feet	7,430,300
Gold refined, ounces	2,540,911
Silver refined, ounces	77,604,483
Lead refined, tons	316,591
Copper refined, pounds	529,686,000
Metal products manufactured, pounds	40,122,817
Metal production and other income:	
Gold	$ 52,515,549
Silver	42,690,226
Lead	24,551,632
Copper	71,712,527
Other metals	2,431,410
Value of products of Company's mines	3,135,809
Value of manufactured products	2,665,958
Miscellaneous income	1,222,514
Total volume of year's business	$200,925,625
Net earnings available for dividends	9,031,565
Net earnings to volume of business, per cent	+4.49

The directors hope that the foregoing information will be of special interest to the stockholders.

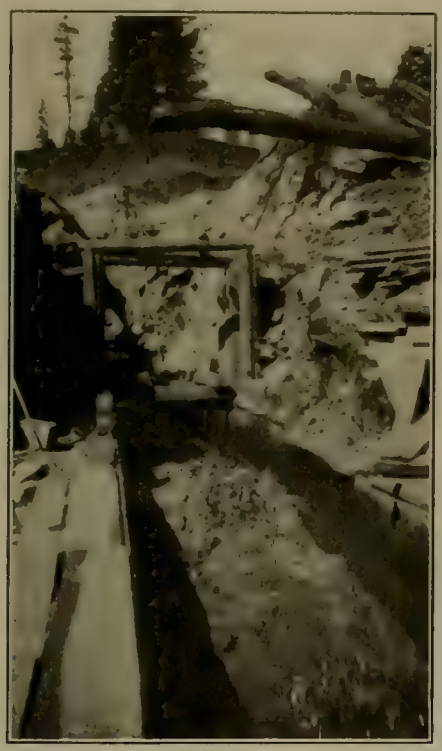
When the American Smelting & Refining Company was organized its business was confined almost entirely to the purchase and smelting of lead-silver ore, refining of gold, silver, and lead, and selling the same. Copper was not sold until 1908. The annual output of copper in America was then 50,000,000 lb. In 1914 it was 529,686,000 pounds.

The Metallurgy of Alluvial Mining

By JOHN M. NICOL

INTRODUCTORY. The purpose of this article is not so much to review the present state of the art as to furnish a critical examination of the principles involved, with a view to suggesting devices that might be more efficient than the ordinary arrangement of sluice-boxes, undercurrents, and gold-saving tables.

Alluvial deposits consist of the detritus resulting from erosion and represent a natural concentration of the more resistant minerals, metals, and gems. These take many varieties of form: blanket deposits from veins; talus deposits partly concentrated by alluvial action, known as *mantas* in Central and South America; recent alluvium in streams; bench placers; old river-channels or 'deep leads'; sea-beach deposits, recent and old.



RACING WATER IN A SLUICE, ILLUSTRATING CONDITIONS UNDER WHICH GOLD IS SUPPOSED TO BE SAVED.

These 'placers,' as they were formerly called by the Western miner, may be worked by a variety of methods, including hand methods for shallow surface deposits, drift-mining for the old buried deep leads, hydraulic mining, elevating, pump-sluicing, and dredging for the large bodies of low-grade gravel. Whatever the metal to be saved or the method used in mining, the metallurgical principles discussed in this article are applicable, although my immediate purpose is to deal mainly with the saving of gold in hydraulic and dredge mining. As a rule, care is taken only to save the chief metal, mineral, or gem, with a consequent neglect to win the possible by-products, which, judging by my own observations, would in many cases be of much value.

PRODUCTS OF PLACERS. In a bulletin of the U. S. Geological Survey, dealing with the so-called 'black sands' of the Pacific slope, on page 54, a list of minerals is given as having been detected during the course of the investigation. Omitting quartz, as normally present, the minerals, in order of frequency are:

Minerals.	Specific gravity. From	To
Magnetite	5.16	5.18
Gold (native)	15.6	19.3
Ilmenite	4.5	5
Garnet	3.15	4.3
Zircon		4.7
Hematite	4.9	5.3
Chromite	4.3	4.6
Platinum (including arsenides)	14	19
Mercury		13.6
Amalgam	13.75	14.1
Feldspar	2.5	2.9
Epidote	3.2	3.5
Olivine	3.2	3.6
Pyrite (chalcopyrite, arsenopyrite, pyrrhotite)	4.9	6.2
Monazite	4.9	5.3
Limonite	3.6	4
Iridosmium	19.3	21.12
Rutile	4.18	4.25
Pyroxene	3.2	3.6
Apatite	3.17	3.23
Titanite	3.4	3.65
Manganese ores	3	4.82
Copper	8.8	8.9
Cinnabar	8	8.2
Cassiterite	6.8	7.1
Tremolite	2.9	3.1
Tourmaline	2.98	3.2
Lead (shot, etc.)		11.37
Wolframite	7.2	7.5
Siderite	3.83	3.88
Corundum	3.95	4.10
Josephinite (awaruite)		8.1
Topaz	3.4	3.65
Scheelite	5.9	6.1
Molybdenite	4.7	4.8
Fluorite	3	3.25
Columbite and tantalite	5.3	7.3

On page 5 of the same publication the following statement is made: "Of the minerals found, the following are evidently saleable wherever found."

Amalgam	Josephinite (alloy of iron and nickel)
Cassiterite (tin)	Lead (bullets, shot, etc.)
Cinnabar	Mercury
Columbite and tantalite	Platiniridium
Corundum (gems)	Palladium (with platinum)
Gold	Platinum
Iridium	Sperrylite
Iridosmium	

Many of the metals of the platinum group and other rare minerals exist in appreciable quantity only in placers.

Unfortunately it is difficult to obtain accurate data concerning the demand for these products, but we may place those most commonly found in the following order of commercial importance: Gold, cassiterite, platinum, gems, iridium, thorium (monazite sand), garnet, and abrasive sand.

Of the rarer metals and minerals found in placers, by far the greater number are only in demand for collections and for experimental purposes. The demand has never been sufficient to stimulate the commercial side of research to a point that would insure means being found to save them as a by-product during the routine work of standard practice. Conversely, the rejection of many of these valuable minerals and metals is also due to the fact that they have not been produced in sufficient quantity to admit of the development of a market that would give them commercial value when used in the arts and manufactures. If demand creates the supply, it is also true that a supply is often a prior requisite for the development of a demand.

The Present State of the Art. The losses that occur in the metallurgical end of placer mining when using the present standard methods are an unknown and unproved quantity. This is largely due to the difficulties of sampling. It must be remembered that, roughly speaking, a drill-sample will only represent something like 1 part in 200,000 to 1 part in 1,000,000 of the body of material to be worked, while in sampling a mine the sample is probably from 1 part in 5200 to 1 part in 10,000.* The sampling of tailing is even more difficult. The difference of opinion on the subject is an added proof of the well known difficulties of correct sampling and of the great variation of the personal equation in this work.

Leaving to one side the question of gem placers, the whole art as at present practised consists of washing and disintegrating the material that has been mined, and passing it (either with or without prior screening of the coarse material) with water, over some form of riffled surface; either sluice-boxes with riffles, or tables covered with canvas or cocoa-matting and expanded metal riffles.

The losses that occur have been discussed by D'Arcy Weatherbe, who says: "In any case, the gold is so excessively fine, particularly at Oroville, that much of it is lost even under the most favorable conditions possible, with the present gold-saving devices. The extent of this loss is not known, as the small amount of research work has given no results of any value. This is one of the features of dredging that surprises the mill-man and metallurgist. * * * A clean-up of the 20th undercurrent of the Spring Valley Hydraulic Co. at Cherokee, Butte county, California, yielded $2600. This gold was taken from material that had been sluiced over 2½ miles of sluices and over 19 other undercurrents, and even then the Chinese were working the tailing below the point; moreover, the gold-saving system of this company was supposed to be the most complete in the state."

Losses occurring in placer mining are due to five grave defects, as follows:

1. The method of saving always aims at making a clear and final separation of the precious metals in a one-stage process.

2. While the mining and sluicing operations are nearly always continuous, the actual removal or saving of precious metals and concentrates is intermittent; there are no means of continuously clearing the riffles as on a table-concentrator used in stamp-mills.

3. The saving of gold or other substance to be saved is entirely dependent upon the classifying action or 'boil' of strong and irregular ascending currents set up by the riffles; the water flowing in the sluices being kept in a sufficiently violent state of agitation to prevent the settlement of anything except gold, platinum, or other metals having a high settling factor; if the boil is not kept strong enough the riffles 'pack' and everything slides over. When the 'boil' is maintained to the point of the riffles being kept clear (the ideal condition of the practical placer miner) all light, flaky, or spongy gold and platinum or any associated minerals that may be valuable for their own, or included precious metal, content, are continuously 'boiled' out from the first to the last riffle, and sent to the tailing-dump.

4. No consideration is given to the possible commercial value of these associated minerals that might be concentrated and saved, or to losses in precious metals occurring as inclusions in heavy concentratable particles, which are now invariably discharged with the tailing.

5. There is no accurate method of assaying the heading and tailing in placer mining, owing to the exceedingly low actual metal-content. The value of that content therefore has to be gauged by a mechanical separation of a large sample; and there is no known convenient method or appliance available for the separation of the by-products.

The losses occurring are, according to my own observations, much more serious than is usually admitted. The losses are especially high in associated and included particles of precious metals existing as concentratable grains of heavy mineral; for reasons given above, it is essential to force this product into the tailing, so as to keep the riffles clean enough to save the gold at all.

In Bulletin No. 45, State Mining Bureau of California, the following statement is made on page 8: "In general the valuable black sand may be described as consisting of hard minerals ranging in specific gravity from 3 to 7, mingled with small percentages of metals and metallic minerals reaching from 7 to 20 in specific gravity. Most of the value will be found in the sand below one-eighth inch diameter of its grain."

And on page 7, referring to the quantity of black sand available, the statement is made that: "In their original condition they form but a small percentage of the grav-

*'Dredging for Gold in California,' by D'Arcy Weatherbe.

els, varying from 0.25c. up to, but seldom exceeding, 2c."

The work that was carried out by David T. Day and R. H. Richards, as was summarized in a bulletin of the U. S. Geological Survey, entitled 'Black Sands of the Pacific Slope, 1907,' was primarily defective in one particular feature. When the original invitation was given for 4-lb. samples, it should have been stipulated that in every case the pounds of black sand or concentratable material per ton of gravel in place must be given, and the relative position of the sample taken, and other data.

In one placer mine that I examined I found in every clean up of the sluices a great quantity of coarse grains of soft red hematite varying from pin heads up to one-quarter inch, and occasionally fragments up to an inch. I collected a fairly large sample and after carefully removing every trace of free gold and black sand, the residue assayed 25.20 oz. in gold and 1.5 oz. in platinum. A concentrate of the screened under-size of 20-mesh made from the tailing of a clean-up from the same mine,

AN UNDERCURRENT, ILLUSTRATING VOLUME OF WATER AND THE 'BOIL' UNDER WHICH GOLD IS SUPPOSED TO BE SAVED.

so that the value of the product could be calculated back into value per cubic yard of average gravel in the mine. Without these details, the work was practically valueless. Nevertheless, from rather unreliable data given under 'Remarks,' we note that the proportion of 'black sand' varies from 1 lb. per 20 cu. yd. of gravel to as high as 650 lb. per ton of gravel. An average of 37 samples from widely scattered points gave approximately 35 lb. of heavy black sand per cubic yard of gravel.

It seems incredible, but owners of mines will not spend the money necessary to prove this crucial point, that is, the proportion and value of concentratable heavy minerals found in the placers; they devote their time and attention solely to free gold that can be caught by known 'riffle' methods.

after carefully removing all free gold and platinum, assayed, gold 19.38 oz., platinum 6.5 oz., osmium-iridium 5.6 oz. per ton of concentrate.

This was clearly in 'included' value. This material had a reducible value of over 35c. per pound, and if therefore there was only one pound per cubic yard of gravel that could be saved, it would more than double the value of the mine; as the free-gold value of the gravel only averaged 18 to 25c. per yard.

My purpose in again raising this vexed problem of 'black sand' is to show clearly that the art of metallurgy in placer mining is defective, and that there is a possibility of saving several metals from the heavy concentrate. I prefer the term 'heavy concentrate' to 'black

sand,' because there are numerous other heavy associated minerals that are not by any means always black, and that may be well worth saving.

STATEMENT OF THE PROBLEM. A clear understanding of the problem that we have to face is essential before we attempt to solve it. Let us take the case of an ordinary gold placer using sluice-box methods of saving.

Let us assume that a cubic yard of gravel weighs approximately 1½ tons; and the precious-metal content is approximately 22½c. of free gold, 875 fine, or worth $18.08 per ounce Troy. Assuming also that by careful hand-concentration tests, it was found that there was 10 lb. of heavy concentrate per cubic yard. Taking no notice of the possible value of the by-products or of the 'included gold' in this heavy concentrate, the problem as gauged by standard methods would be as follows:

In one operation to separate and save six grains Troy of gold, out of a mass of 10 lb. (70,000 Troy grains) of heavy concentrate and the accompanying 2990 lb. of gravel and sand. In other words, to save 6 grains out of 21,000,000 grains. And this at a cost not to exceed 5c. for mining, metallurgical, overhead, and all other charges. It is evident that, owing to the great tonnage handled in placer operations, any saving in cost, or increase in amount of saleable products—counted even in fractions of a cent per yard—is worthy of careful consideration.

There are two principal avenues for the loss of gold:

(*a*) Owing to the necessity, in the one-stage sluice-box method of gold-saving, of maintaining the velocity and supporting power of the current, and the 'boil' or ascending currents in the riffles, in such a state of activity as to prevent the settlement of black sand, and other heavy concentrate, there is no doubt that a great deal of spongy, flaky, rusty, and fine gold, whose settling factors approximate that of the 'heavy concentrate' is carried forward and never has a chance to settle either in the first or the last sluice-box.

(*b*) All of the 'included' gold in fragments of other heavy minerals is also lost for the reason that the heavy concentrate is deliberately boiled out and carried forward.

A great deal of time and ingenuity have been expended in designing riffles and special appliances to keep the riffles clear, overlooking the fact that this must also cause the loss of much fine gold.

Therefore I arrive at the following conclusion: Any form of riffle that does not 'boil' will pack, and all material will pass over and no gold will be caught. Any form of riffle that 'boils' effectively will keep itself clear and in an efficient state to catch gold, but at the expense of practically all of the 'heavy concentrate' and of a certain amount of fine gold, and of nearly all of the spongy or flaky gold, whose settling factor approximates the heavy concentrate, and also of all of the included gold in the heavy concentrate.

The above conclusion applies in varying degree to all fixed riffle-surfaces, sluice-boxes, undercurrents, and canvas tables.

SUGGESTIONS FOR THE SOLUTION OF THE PROBLEM:

1. To use the ordinary sluice-box mainly as a washing, disintegrating, and transporting appliance; and as a metallurgical appliance merely to save the coarse and easily caught gold. Short sections of these main sluices to be in duplicate, and parallel so as to admit of frequent 'clean-ups.'

2. To screen and eliminate, at as early a stage as possible, all coarse material (say about ¾ in.) after it has been thoroughly disintegrated and washed.

3. To eliminate entirely the fixed-riffle undercurrent, expanded metal, canvas table, etc., and to avoid any attempt to make a one-stage separation of the fine gold.

4. To dewater the undersize product of the screens, by some form of simple spitzkasten.

5. To use some form of concentrating device in which the riffles move continuously at right angles to the direction of the flow of sand, with an adjustable travel, so that all of the concentratable heavy particles can be caught, together with the fine gold, and separated afterward by more refined methods. In other words, get away from the 'boil' in the riffles, catch everything that is heavy, and separate the free gold afterward.

6. Use a second-stage screen, send all the dewatered oversize to picking-belt conveyor, and by this means either to the dump or to a crusher, for further treatment, according to its assay-value.

7. Dewater and dry all the fine concentrate, the undersize from the screen. The amount of this concentrate that would require drying, in most placer mines, would not be excessive. At 50 lb. per yard in the 2000 yd. per day mine it would amount to 50 tons. This is a large amount; usually it would be only a few tons per day.

8. Use magnetic separators of special design to remove all magnetic material, generally the true 'black sand.'

9. Add water to the non-magnetic residue and pass over refined concentrating tables, capable of making several separations, preferably at least five. The No. 1 and 2 concentrates of these tables would contain most of the gold and platinum, and so they would represent a very reduced volume of the original gravel, and would probably be high-grade; they might be treated either by smelting in crucibles, or by pan-amalgamation, using sodium amalgam for the separation of the platinum; or they might be sold direct to the refiners.

10. The treatment of the other by-products would depend on what was found.

(To be Continued)

HYDROTHERMAL METAMORPHISM is frequently so profound as to change materially the chemical and mineralogical composition of large areas of rocks. It is only rarely, however, that this process can actually be seen occurring at the present time, under conditions which permit the changes to be traced through their various steps. It is still more exceptional to find recognizable cases where this alteration has gone to so complete a stage that the end products consist of residual soils, essentially in the ultimate stage of decay.

Secondary Sulphide Enrichment of Copper Ores

By ARTHUR L. DAY

*Since about the year 1900 the problem of the secondary enrichment of ores has been growing in interest, and certain phases of it have been studied as opportunity offered, both in the laboratory and in the field. In 1911, L. C. Graton, of Harvard University, planned a much more comprehensive study than has been undertaken hitherto, of one particular phase of this problem, namely, the secondary sulphide enrichment of copper ores. He was fortunately able to enlist the interest and the co-operation of the copper-mining companies, which secured for him special privileges to examine all the principal copper-sulphide mining districts of North America.

This fact of itself is of more than passing interest, for although co-operation between science and industry has been much cultivated in other countries, notably in Germany, and without recorded exception has resulted in great advantages to both participants, but little open co-operation of this character has been attempted in the United States. There would seem to be no reason why American science and industry might not enjoy similar benefits where their common interests are involved.

Recognizing the necessity for laboratory studies on the conditions of formation of the copper-sulphide minerals, the means for identifying them, and the alterations to which they are subject, Mr. Graton proposed to this laboratory that such investigations be undertaken here in direct collaboration with those who might be chosen to undertake the systematic field investigation which he proposed to begin. After some consideration of the scope of the plan proposed, which was rather too large for the resources at our disposal for such a purpose, but in full appreciation of the advantages which such co-operation might offer, the invitation was accepted. In fact, at the moment when the invitation was received, laboratory work on the stability of the sulphides of copper and the relations between them was already in progress, following upon similar work upon the sulphides of iron, of cadmium, and of mercury, the successful results of which enabled us to proceed with full confidence in the outcome of the larger plan now proposed. The difficulty in the matter of resources was happily removed by an allotment from the funds at the disposal of Mr. Graton.

Thus the systematic study of one of the larger problems of geology, a problem of interest equally from the scientific and the economic viewpoints, was begun early in 1912 under the most favorable conditions and has been conducted with vigor and success since that time. Some details of the plan as at first proposed were contained in the annual report of this laboratory for 1913. The present status of the investigation, or rather of the laboratory portion of it, follows.

*From the annual report of the Director of the Geophysical Laboratory of the Carnegie Institution.

WHAT IS SECONDARY ENRICHMENT? It is now generally conceded that when the sulphides of an orebody oxidize at the surface of the ground and pass into the soluble form, they are carried down by percolating waters and re-precipitated on the surface of the still unoxidized sulphides below. The chemical reactions involved in this process and the physical conditions which favor them have been heretofore only matters of conjecture. The laboratory problem involves the elucidation of these processes, as well as the somewhat broader problem of the stability relations between copper and the copper and iron sulphides: chalcocite Cu_2S, covellite CuS, chalcopyrite $CuFeS_2$, and bornite Cu_2FeS_4; it involves the synthesis of these sulphides under known conditions, including, of course, the conditions of natural formation where known and the most important alterations which are found to occur.

The most obvious manner of attack is to start from the pure chemical elements copper and sulphur, and from these to endeavor to make, in the laboratory and under measured conditions, the compounds of these, or, in a word, to study the relations between pure copper and pure sulphur over a sufficient temperature range to include all the natural combinations of these two substances which are known. Heating these two elements together results first of all in the formation of the simple 1:1 compound CuS, corresponding to the mineral covellite, which then appears stable up to about 360°C. Beyond this temperature (in H_2S at atmospheric pressure) it begins to lose S, but microscopic examination shows that the mass remains homogeneous, which may be interpreted to mean that the covellite has lost its stability and yielded place to a lower sulphide of copper carrying sulphur in solution. Continued heating drives out this dissolved sulphur gradually, until in vacuo at 1127°C. the charge melts as Cu_2S, corresponding to the natural mineral chalcocite. The progress of this reaction has been checked by observation at several intermediate temperatures, at each of which the charge is exposed until no further change occurs there, after which the product is examined. The results are tabulated below:

Temperature, °C.	Dissolved sulphur, %	Specific gravity (25°).	Color.	Product.
410	2.89	5.562	Light	$Cu_2S(S)_x$
485	2.32	5.638	Darker	$Cu_2S(S)_x$
700	1.75	5.666	Still darker	$Cu_2S(S)_x$
1050	1.66	5.675	Do	$Cu_2S(S)_x$
1060	1.66	Melting temperature in H_2S (1 atm.)		$Cu_2S(S)_x$
1127	0	Melting temperature in vacuo		Cu_2S

The change in the measured properties is thus shown

to be a continuous one, and the sulphur in solution is found to lower the melting temperature of chalcocite, as might be expected. The relation of these intermediate solutions to chalcocite and covellite is in every way analogous to the relations of the various pyrrhotites, $FeS.S_x$, to ferrous sulphide and pyrite, and since the pyrrhotites are common in nature, chalcocite solutions might also be expected. Nevertheless, the field evidence shows that whereas the pyrrhotites are found more commonly in nature than ferrous sulphide, Cu_2S is certainly more common alone than with excess sulphur in solution.

Thus far, chalcocite alone has not been obtained in the wet way from cupric solutions, but mixtures of the covellite result. When covellite is heated with an excess of alkali sulphide, a part of it is changed into chalcocite with formation of polysulphide, while when polysulphide is heated with chalcocite, part of the latter becomes covellite. The reaction $Cu_2S + Na_2S_2 = 2CuS + Na_2S$ is therefore reversible. At this point the investigation was interrupted until a method could be worked out for the determination of covellite and chalcocite, each in the presence of the other, and this has now been successfully accomplished.

Simultaneously with the above investigation of the relations between sulphur and copper, a similar study of the system copper, iron, and sulphur was undertaken, and, although more complicated than the first, is also well advanced. Chalcopyrite and bornite have both been successfully prepared in the laboratory and a method for their determination is available. Also the composition of pure bornite has been found not to be Cu_3FeS_3 as commonly stated in the books, but Cu_5FeS_4.

Conjointly with these experiments on the formation of the copper-sulphide minerals and their relations, direct experiments have been in progress for some time on the changes which actually take place during the processes of secondary sulphide enrichment. In nature we find indications that the solutions from the oxidized sulphide zone have produced a series of changes in the sulphides beneath them, as follows:

Pyrite changes to chalcopyrite..... $FeS_2 \rightarrow CuFeS_2$
Chalcopyrite changes to bornite..... $CuFeS_2 \rightarrow Cu_5FeS_4$
Bornite changes to covellite..... $Cu_5FeS_4 \rightarrow CuS$
Covellite changes to chalcocite..... $CuS \rightarrow Cu_2S$
Chalcocite (rarely) changes to copper. $Cu_2S \rightarrow Cu$

After more than a year of work, we now know that all these changes can also be effected in the laboratory by the action of copper-sulphate solutions on the sulphides, and will therefore be accessible to detailed study. Most of these changes are very slow at low temperatures and more rapid at higher ones. The laboratory work has therefore been done for the most part at 200°C., but the same reactions have been found to occur at 100°C., and indications of the same reactions or some of them were also found at 30 C. The conditions of deposition in nature are therefore also accessible and the results comparable with those of the laboratory. Moreover, these reactions have been worked out in a quantitative way, that is, the quantities of all the products formed have been carefully determined. The ratios of the iron dissolved and of the sulphuric acid which is formed to the copper precipitated have been determined in all the cases. In some of the cases chemical separations of the products can also be made. Thus the following changes have been established:

Pyrite to chalcocite..... $FeS_2 \rightarrow Cu_2S$
Covellite to chalcocite..... $CuS \rightarrow Cu_2S$
Chalcopyrite to chalcocite..... $CuFeS_2 \rightarrow Cu_2S$
Pyrrhotite to chalcopyrite..... $FeS(S)_x \rightarrow CuFeS_2$
Bornite to chalcocite and covellite. $Cu_5FeS_4 \rightarrow CuS + Cu_2S$

Color changes and incomplete chemical investigations indicate also:

Pyrite to chalcopyrite ..... $FeS_2 \rightarrow CuFeS_2$
Pyrite to bornite..... $FeS_2 \rightarrow Cu_5FeS_4$

Again, the change at ordinary temperatures from pyrite to covellite and chalcocite, $FeS_2 \rightarrow Cu_2S$ and CuS, has been quantitatively worked out and at 300°C. we have found the change $Cu_2S \rightarrow Cu$. All these changes involve an increase of copper in the product, that is, an enrichment.

Thus far, the conditions which determine any particular one of these changes at 200°C. can only be stated in general terms; thus, for example, the higher the concentration of copper solutions and the longer the time and the greater the surface of sulphide exposed, the farther the change will go. A large surface of pyrite and a dilute copper solution gives at first considerable chalcopyrite, but eventually all becomes chalcocite. Certainly none of the intermediate copper sulphides between pyrite and native copper can be regarded as stable in the presence of copper sulphate solutions. Since sulphuric acid is one of the products formed in the oxidation zone whenever pyrite, marcasite, or pyrrhotite is present, we have studied the effect of copper-sulphate solutions on the common sulphides in the presence of acid as well as in neutral solutions. In one instance (the change from pyrite to chalcocite), acid has been found to retard the precipitation of copper; that is, the enrichment process. Now, mine waters have been proved to be less acid the lower the level. The acid is neutralized by various minerals, like the carbonates, feldspars, and others, with which the solutions come in contact. Therefore we should expect that enrichment would go on more rapidly at some distance below the surface, the distance depending on local conditions.

In these various ways the problem is leading to a series of reactions bounded by definite conditions which admit of laboratory study and precise definition. This problem will be pursued actively during the coming year.

DECOMPOSITION of any rock is accomplished by the removal of the more soluble bases, and a concentration of the relatively insoluble oxides of iron, aluminum, and silicon. By reason of its somewhat greater solubility, silica is much more subject to removal than iron and alumina. The two important residual end-products of weathering are sand and clay.

CONCENTRATES

Readers of the MINING AND SCIENTIFIC PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

NICKEL added to steel up to 3.5% increases its strength and elastic limit.

FELSITE is a general term applied to light-colored fine-grained igneous rocks, chiefly altered rhyolites.

CRUSTIFICATION is a banded structure produced by successive deposition of different layers on the walls of a vein or other ore-opening.

FIFTY SAMPLES of mine-water from mines producing sulphide ore throughout the world showed that 22 were acid, 14 neutral, and 14 alkaline.

LUBRICATION is necessary to diminish friction and conserve power. A shaft should not come in contact with a bearing, it should revolve on a thin layer of oil.

SPONGE PLATINUM recovered in refining over 3,000,000 oz. of gold bullion in U. S. mints in 1912-1913 amounted to 1666.94 oz. Palladium saved was 28.25 ounces.

POROUS STONE and brick may be made non-porous by the use of some fatty or oily varnish which will sink into it. These applications must be renewed from time to time.

PROBABLY nine out of ten ore deposits have some visible relation to a body of igneous rock. In general, a region free from igneous rocks is not characterized by ore.

GREENSTONE is a general name applied to certain igneous rocks, generally fine-grained, of a dark-green color. The term is used when no accurate determination is possible.

QUICKSILVER VERMILION is the amorphous mercury sulphide, which is normally black, but when made with sulphur in the presence of an alkaline solution it becomes bright red.

DRAG is the name given to fragments of ore torn from a lode by a fault. Such fragments are scattered along the line of the fault and are usually enclosed within crushed or brecciated pieces of the rock traversed by that fault. Secondary mineralization along the fault may obscure the true character of the 'drag' in which case the difference in associated minerals may prove suggestive.

MANGANESE STEEL is brittle when slowly cooled. On heating to nearly a white heat and plunging into water, it becomes tough and ductile, a reversal of the ordinary condition.

METALLIFEROUS VEINS have been formed at every period of the earth's history, but a large proportion of the richer concentrations have been made after the later periods of volcanic activity.

COLLOIDAL SELENIUM can be prepared by dissolving freshly-prepared $SeBr_4$ in a hydrobromic acid. This gives a clear brown solution that on dilution gives colloidal selenium.

THE ATOMIC WEIGHT of lead has been under investigation at Harvard for several years. Baxter, Thorvaldson, and Grover's experiments on lead bromide and lead chloride prove lead to average 207.19.

BISMUTHINITE is the sulphide, and bismuthite the carbonate, of bismuth. Bismite is the oxide; also called bismuth ochre. The first of these characterizes the rich sulphide ore found in the deeper workings at Goldfield, Nevada.

SULPHURIC ACID production is second on the list of products known as chemicals; fertilizers are first, being about double the tonnage of the acid. In making fertilizers, 52% of the sulphuric acid manufactured is consumed. In oil refining, 11.7% is used.

WHEREVER WATER has to be cooled for condensers, transformers, or water-jackets, a spray system, properly designed, is considered by some engineers to be the most efficient to operate. It also costs much less to install than any other system of cooling water, and where there is an existing pond, the cost is limited to the spray nozzles and piping. In a spray system, the hot water is cooled by spraying it into the air so that when it falls

into a basin or pond, its temperature is sufficiently reduced to permit of it being used over again. Cooling towers are used in many countries. They are also efficient. They are inexpensive to erect.

IMPURITIES in zinc that affect rolling into sheets are lead, iron, and oxygen. Up to 1.5% of lead and 0.125% iron does not interfere with rolling. Oxygen may occur as zinc oxide. Cadmium is not harmful up to 1.5%. Copper, tin, and arsenic render spelter hard and brittle.

CHILE SALTPETRE sold for $14.50 per hundredweight (112 lb.) in Moscow during March, as compared to a normal price of $2.85. At the petition of manufacturers of chemicals and explosives the import duty has been removed. Means of increasing imports are being discussed.

LIMESTONE containing appreciable quantities of impurities sufficient to give the calcined product hydraulic properties, but insufficient to take up all the lime present, makes, when burned, hydraulic lime. This is an intermediate product between ordinary lime and natural cement.

SALT in sea-water amounts to about 3%; in Great Salt Lake, 9.7%; in the Dead Sea, 10%; and in some gold mines in Western Australia, 10 to 25%. As regards the last it is a coincidence that the majority of the properties which yield a large quantity of salt water, do not produce much gold.

PUMPING-STATION at the 18th level of the Old Dominion copper mine, Arizona, is 15 ft. high, 20 ft. wide, and 55 ft. long. The roof is supported by steel columns. A motor-driven Aldrich pump, of 1200-gal. per minute capacity, is at work. In 1914 this mine produced 1,349,210,000 gal. of water.

FUEL is a substance whose combustion in atmospheric oxygen can be utilized as a source of heat energy for commercial or domestic purposes. Fuels are most conveniently considered as divided into three natural divisions, namely, solid, liquid, and gaseous. The two elements which contribute most to the heating power of fuel are carbon and hydrogen.

THE IDEA that veins in granite are short-lived is a common fallacy. 'Granite' is a term open to various interpretations. It can be stated that the mines of Butte, for example, are in rock of granitoid character, so also are the tin mines of Cornwall. The edges of granite areas, in contact with eruptive rocks, are particularly susceptible to mineral impregnation.

GOLD REFINING in Australian mints is done by the Miller chlorine process. Gas is passed into molten metal. In America the electrolytic method prevails. The latter is considerably slower than the former. In Europe sulphuric acid is used. The quantity of gold annually refined by these processes is £10,000,000, £15,000,000, and £70,000,000 respectively. The advantages of the existing methods are sufficiently nearly balanced at present for the preference shown to one or other of them to depend largely on local conditions.

TURBO-GENERATORS should be connected with a filter of some type to supply clean air for the generators. In Germany this is a feature of all plants. Air passages are liable to get clogged. The capacity of the machine is reduced. This often results in burning out coils. In some plants the generators are cleaned with compressed air. This is not good practice. A machine cannot be stopped for cleaning.

WATER from regions of old rocks like granite is low in mineral content. That from limestone areas is hard. Alkali country gives water a high sodium and potassium content. Swampy water is highly colored. Water flowing through easily disintegrated material like clay is muddy. Drainage from basins with small rainfall is more highly mineralized than that from more humid areas. Ground water is usually higher in mineral than surface water of the same locality. The former is clear, the latter dirty. All of these points should be studied by mining and metallurgical engineers. Good water is a necessity in all mining operations.

ORE from the Youanme mine, Western Australia, contains gold-bearing quartz and iron pyrite, with 0.21% antimony and 0.96% arsenic. Wet crushing, amalgamation, and cyanidation; concentration after crushing, grinding, and slime treatment; concentration by flotation; bromo-cyanide and Gitsham processes; and preliminary caustic soda treatment all failed to give good results. The following process was finally adopted: jaw-crusher, revolving cylindrical drier, No. 8 Krupp ball-mill, Edwards duplex roasting furnace, pulp mixer, fine grinding, filtering, and zinc-dust precipitation. The recovery is 84%, at a cost of $2.16 per ton. The residue assays $1.68 per ton. Cyanide consumption is 1 lb. per ton.

ZINC is used in boilers to prevent scale formation and pitting. Recently there was exported from the United States 400,000 lb. of pure zinc, in the form of plates ½ in. thick, 4 in. wide, and 6 in. long. They had a ½-in. hole bored through the centre. They were to be used in boilers as follows: A steel rod is introduced through the side of a boiler. The plates, together with steel or iron washers, are strung on the rod in alternate layers, so that there is constant contact between the zinc and the iron all the way across the boiler. When the boiler is in use, this arrangement of the two metals constitutes an electric couple. A galvanic current of electricity is set up inside the boiler which, it is claimed, effectively prevents not only foaming of the boiler, but also the deposition of scale. In this way the use of various materials known as boiler compounds is eliminated, and the boiler is kept in good, clean condition for an indefinite period. Aluminum plates act in the same way.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

MIAMI, ARIZONA

NEW SMELTER IN OPERATION.—CAPACITY.—COST.—ROASTING PLANT.—BEDDING BINS.—LIME SUPPLY.

The new smelter of the International Smelting & Refining Co. has started. It has a capacity of 250 tons of copper per day. It was erected primarily to treat concentrate from the Inspiration and Miami mills nearby. It will also reduce custom ore from mines in the Miami, Ray, and Superior districts. This is important for the district. The plant has cost approximately $2,200,000. Estimates were $2,000,000. Improvements in smelting practice caused the increase. L. R. Wallace is in charge.

One of the most interesting features of the equipment is the roasting plant used for ores and concentrates. Its arrangement shows the probable manufacture of sulphuric acid in the future. This would be for leaching purposes. Although it is for roasting, only enough heat is being applied to dry the

VIEW FROM MOONSHINE HILL, MIAMI. NEW INSPIRATION MILL, INTERNATIONAL SMELTER, POWER-PLANT, AND GULCH ON LEFT THAT WILL HOLD 90,000,000 TONS OF TAILING AND SLAG.

material for smelting. Furnaces are of the super-imposed hearth type, familiar to metallurgists. They are fired with oil. This fuel is generally used throughout the smelter. At present the oil is being fed mixed with steam, but as soon as the compressed-air supply is ready, steam will be used only in coils in the bottom of the oil tanks to keep the fuel easy to handle. The oil is received at the plant in a tank holding about 200 bbl. Then it is pumped into a main supply tank of 30,000-gal. capacity, and it then flows into eight measuring tanks, holding 200 bbl. each. These make possible an accurate control of the oil supply, showing exactly the amount being used for any given time.

A scale-hopper weighs each charge as it enters the converter. Three bedding-bins are used to hold the mixture of ore and flux before entering the plant, the material being brought to the bins by a conveyor and mixed by traveling distributers. At present, concentrates, sulphide ore from Bisbee, lime, and iron, are being mixed in the central bin. The mixture is being made low grade to avoid possibility of burning out the bottom of the reverberatories in starting. After the furnaces are partly filled, the charges will be of higher value. At one end of the converter floor is a large grizzly surmounted by a travelling pile-driver. It is for breaking old shells from the converters. The broken material drops into cars and is re-smelted.

At present the International company is buying lime from the Old Dominion, at Globe, four miles away. It has a quarry and crusher on the Copper Hill railway. In the event of the lime required reaching an amount which would make it more economical to quarry its own flux, the smelting company will build a line to its large limestone deposit about a mile northwest of the plant.

No. 1 reverberatory furnace was charged with roasted concentrate on May 17. Waste heat from the reverberatories will generate steam in Stirling boilers in the usual way. The converting department is ready to receive matte. The Cottrell electrolytic dust-saving process is working in connection with the Wedge roasting furnaces. This system is fairly well understood by metallurgists, and needs no further description. Another installation is being fitted in the converter flue.

At the Warrior 60 men are working. Ore shipments to El Paso and Hayden average 5 to 7% copper.——Patrick P. Sullivan, well known at Globe, and associates in 22 claims adjoining the Warrior and Inspiration, are preparing for churn-drilling. They expect to cut the Warrior ore dipping west between the dacite hanging wall and schist foot-wall.——Encouraging results are reported from the Cole-Goodwin.——The Savage claims, one mile west of the Gibson, are considered among the best prospects of the Miami district. Adits have exposed a strong vein. The Miami Development company and Stoll & Jones have bonded the property.

GOLDFIELD, NEVADA

ROUND MOUNTAIN.—JUMBO EXTENSION, ATLANTA, SANDSTORM, KENDALL, ORO, SILVER PICK, COMBINATION FRACTION, AND KEWANAS.

The annual meeting of the Round Mountain Mining Co. was held in Goldfield on May 17. James R. Davis was again elected president and manager, Louis D. Gordon vice-president, H. G. Mayer secretary and treasurer, with W. H. Webber and W. C. Erb additional directors. Mr. Davis reported good progress in laying the pipe-line from Jett cañon to the mine, eight miles, to supply water for sluicing. This will commence between June 1 and 15. The company's mill is working as usual. A new orebody has been opened on the 800-ft. level.

Equipment for the Velvet shaft of the Jumbo Extension company is being installed. It includes a double-drum electric-hoist, 100-hp. motor, Cameron Pump, and air connection. Air will be supplied from the 16-drill compressor at the Polverde shaft. Sinking will begin within the next 10 days. This shaft will be sunk as quickly as possible to 1017 ft. Then connection will be made with the deepest workings from the Polverde shaft, 500 ft. distant. In new workings, southwest of the 1017-ft. level rises, No. 524 drift and 507 cross-cut have exposed ore of uniformly high grade along the latite-shale contact for a length of 400 ft. The contact area both above and below this point, which is at a depth of 884 ft., is all virgin ground. This work follows the surface of the shale almost due east. As the contact ore-channel is shown to extend slightly east of south, along the dip of the shale, it is apparent that the area of enrichment is considerable. All work has been confined to development for some time past. Occasional shipments are made to

relieve congestion in the bins. A rise is being driven from the south drift at 1017 ft. to reach the shale contact. This drift has continued for over 100 ft. in the large fissure that extends into the shale. On the 790-ft. level a cross-cut far to the east, near the Velvet shaft, has exposed large quantities of $6 to $12 ore. This is apparently in the main Velvet vein, in the latite, well above the shale. A special shareholders' meeting was held at Phoenix, Arizona on May 20 to ratify the agreement with the Reorganized Booth Mining Co., and to increase the capital of the Jumbo Extension, in order that 300,000 shares might be transferred to the Booth company in payment for the cession of apex rights.

The Atlanta company is shipping at the rate of 50 tons daily. Shipments are usually made every other day, to effect a saving in sampling and handling the product at the mine. The average value is from $27 to $30 per ton. Stoping is in progress from the incline cross-cut in ore, 115 ft. above the 1750-ft. level, and extending toward the adjoining Grizzly Bear ground on its pitch to the north. From a point 50 ft. higher in the air-rise, another cross-cut will be driven to the stope for air. This will be done at intervals of 50 ft. At a point in the air rise, 80 ft. below the 1400-ft. level, seams of ore were exposed, assaying 3½ oz. gold. Work will soon begin at this depth. From the main stope a drift, known as 1013, is being advanced south, on the vein, to connect with rises 1011-A and 1012-A, over 200 ft. south. Both are in good ore. A rise has just been started 300 ft. south of the new workings, on a body of $27 ore exposed over a year ago in the first work on the 1750-ft. level. The main cross-cut, from which the newer workings have been opened, in its progress from the hanging to the foot-wall, cut the vein diagonally. It was in profitable ore for 107 ft. The company's engineers are already considering the practicability of an oil-flotation plant. Ore now being shipped contains from 5 to 8% copper.

Sinking has been resumed by the Sandstorm-Kendall company at a depth of 550 ft. An electric-hoist has been installed at the collar of the winze on the 500-ft. level. This replaces the windlass used to sink 50 ft., following the incline of the vein. This incline will be followed, with the purpose of finally reaching the point of contact between this vein and the shale. The vein is regarded by engineers as one of great promise. It produced a good tonnage of rich ore nearer the surface. Tests of the company's placer ground, which were delayed by storms, will now proceed, for the purpose of determining whether better results can be obtained by washing, or by screening and washing combined.

The Goldfield Oro is now working on the 800-ft. level where strong seams of ore have been exposed lately. The ground is broken, and has given considerable trouble at 700 and 800 ft. ——Silver Pick Con. is extending a cross-cut west from the new station at 700-ft., to reach a large vein that was cut on the 500-ft. level.——Combination Fraction lessees have cut a seam of high-grade ore. They are rising to develop the vein. ——At the Kewanas development continues at 840 ft. along the latite-shale contact, in a fissure that penetrates the shale.

TORONTO, ONTARIO

Dome Mines Co.—Hollinger and Acme.—Huronia.—McIntyre.—Dome Lake.—Nickel.

At a meeting of the directors of the Dome Mines, held in New York on April 30, it was decided to issue 50,000 shares of treasury stock at par, *pro rata* to shareholders of record June 26. At the present price of the shares this will be equivalent to a dividend of 40c. per share. The authorized capital of the company is $5,000,000. The new shares will bring the issued capital up to $4,000,000. The money raised will be used to finance new development, and to provide for a number of new buildings. It is expected that a large proportion of the total amount will be held in reserve to pay for new additions to the mill. These will probably be built this year. The annual meeting of the company will be held in Toronto on May 25. The report is expected to show a profit of over $1 per ton during the past year. It is also expected that at this meeting some definite program regarding the future dividend policy will be announced. The property is in excellent condition. The recent discoveries on No. 6 level, in addition to the favorable developments on No. 4 and 5 levels, have greatly improved the outlook.

Hollinger shares continue to make new high records with monotonous regularity. This advance, aside from the excellent results from the property, is largely based on the expectation that Hollinger shareholders will participate in the flotation of the Acme company on an attractive basis. So far however, nothing definite has been done regarding the issue of Acme shares. When these eventually are offered, it is probable that the Hollinger and the Acme will be consolidated. At the Hollinger the new central shaft is down 425 ft. A station is being cut at that depth. It is to be sunk to 1200 ft. The winze below 800 ft. is down 100 ft. Early in June development of No. 1 vein at 925 ft. will be started. Results at 800 ft. are good.

It is understood that the Canadian Mines and Finance Co., which controls the above, has taken an option on the Huronia mine near Kirkland Lake. This property, owned by Montreal people, is equipped with a plant and a small mill. After operating the latter for several months, the company was forced to stop operations on account of a lack of funds. About $400,000 has been spent to date. The property is now being examined and sampled and if the results are satisfactory, work will be started June 1.

The McIntyre mill is treating about 300 tons per day. Gross profits for April are expected to be $40,000. This will be sufficient to clear the deficit and leave a surplus. The financial statement of the company for the year ending March 31, 1915 shows current assets of $102,782. This includes $1840 cash, and $46,791 bullion. Current liabilities, including a bank overdraft of $57,507, are $114,704 leaving a deficit on current account of $12,000.

The Dome Lake mine was closed down on May 1 to permit of necessary repairs to the mill and also to an adjustment in the wage scale. All the men were discharged. It is expected that the majority will be re-employed at a lower rate of wages to conform to the wage-scale that is in effect at the other mines of the district. This step was considered necessary to avoid the provisions of the Lemieux Act, which requires a notice of 30 days before any cut in wages can go into effect. Economies will be effected in all departments. It is hoped that when these changes are made the property will be able to make a profit of about $4000 per month. As the ore reserves are small, and the company owes the Hudson Bay Mines, the controlling company, about $80,000 for money advanced, the prospects for the shareholders cannot be considered very encouraging.

Results on the Vipond continue to be satisfactory. It has been decided to increase the capacity of the plant to 120 tons per day.——The North Thompson, which adjoins the Vipond is to be re-opened. A contract has been let for the sinking of a 300-ft. shaft.

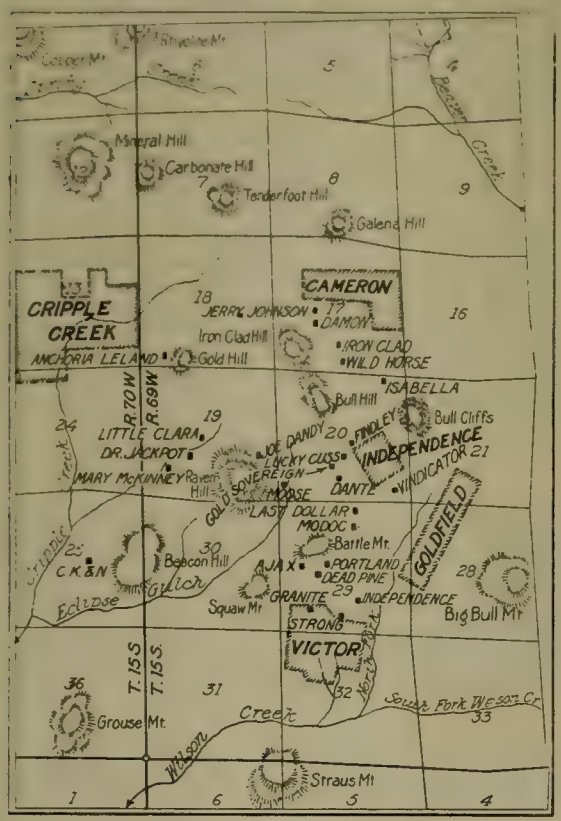
Directors of the International Nickel Co. have declared the regular quarterly dividend of 2½% and an extra bonus of 2½% payable June 1. The heavy demand for nickel to be used in the manufacture of munitions of war, as well as for industrial purposes, has resulted in the heaviest sales in the history of the company. The large supplies of refined nickel on hand at the refinery at New Jersey have all been used. In order to cope with requirements the company will install another blast-furnace. A new five-compartment shaft is being sunk at the Creighton mine. New hoisting equipment will also be installed and a new rock-crusher and sorting-house built.

The Huronia mine in Gauthier township is to be developed by L. H. and N. A. Timmins, who are also interested in the Hollinger. The workings are being sampled.

CRIPPLE CREEK, COLORADO

PROPERTY CONSOLIDATIONS—STRATTON'S AND PORTLAND.—ISABELLA LESSEES.—MINING DUMPS.

Topics of interest in this district during the past week were mergers and rumors of mergers. It is now stated that A. E. Carlton proposes a merger of the Vindicator, United Gold Mines, Findley, and others, to form a new company and keep the mining company separate from the milling or Golden Cycle Reduction Co. This is regarded as improbable, as the Vindicator, which recently bought the Golden Cycle mine, is pretty well satisfied at present. Mr. Carlton's holdings in the Vindicator are hardly large enough to change the policy of the company. A more probable combination would be to separate the Golden Cycle Mining & Reduction Co. into its component parts, namely, the Golden Cycle mill, the United Gold



CRIPPLE CREEK DISTRICT.

Mines, Trail, Findley, and other mines. Meanwhile rumors are numerous, and nearly every property in the district has been merged with some other in popular discussion.

The Stratton's Independence mine has been sold to the Portland Gold Mining Co. as a going concern for the sum of $300,000. The further allowance for stores on hand, etc., will bring the total close up to $375,000. This is a wise move on the part of Stratton's Independence, for with the big dumps exhausted and only a small showing of ore in the mine the company could not hope to exist much longer. The Portland company will be enabled to mill its dump at the No. 1 shaft through the Independence mill and save an expensive double handling on this material. The Portland mill was built on the top of Battle mountain, so that crude ore and supplies have to be pulled up to it and tailing pulled away from it. The disposition of the tailing has reached a critical stage with them, so much so that it would not be surprising to see the mill taken down and added to the Independence mill. Incidentally, the Portland company will now be able to take care of low-grade custom ore here in the district and save—as against the Golden Cycle Co.—the haul to Colorado City. Indeed, a great many possibilities are now before the Portland company. The Independence company maintains its existence and will proceed at once to acquire new property, according to the will of the shareholders as expressed at the meeting held in London on May 17.

Clark Mitchell, superintendent of the Isabella, recently made public a commendable report on the general conditions at this important property. He has succeeded, in face of great odds, in putting this property back on the list of large producers, and is entitled to great credit. He says, in part: "Forty-five sets of lessees are now operating, several of them meeting with splendid success. Just recently a very important find was made at the 14th level of the Lee shaft, on company account, in a region where very little development has ever been done. There is every indication that we have something new and big, better, in fact, than we had on the Isabella in years."

With the coming of warm weather great activity is apparent on the various dumps of the large mines. It is surprising the amount and grade of the shipments from these sources in a summer. About 150 men are already at work and the next few weeks will see that number doubled.

BOSTON

COPPER AND ZINC DIVIDENDS.—WEST VIRGINIA MINING CO.—JUNEAU STOCKS.—NORTH BUTTE.

Meetings of several copper companies in the latter part of May for dividend action have aroused interest. People are wondering what the increased prices of copper and zinc will do in the way of distributions to stockholders. It seems to be a certainty that Butte & Superior will increase its regular dividend rate, or else yield to the pressure for a large extra disbursement. The directors will probably feel compelled to distribute some of the company's great profits. Utah Copper is earning about $15 per share, yet it sticks to the $3 annual rate. This, however, it maintained through the latter part of 1914, a period which caused even Calumet & Hecla to pass payments in its 50-year dividend history. The position of the 'porphyries' is strong. Their handling has been conservative. It is possible that Chino will restore the 75c. quarterly rate, and Ray Consolidated will resume its interrupted dividend payments of 37½c. per quarter. Some surprise was expressed at the failure of the Granby directors to resume dividends at the meeting this month. Granby is in position to pay larger dividends than ever before. While the copper and zinc company managements are looking for at least two or three years of high prices, they are proceeding, as a rule, with great caution in the matter of increasing regular dividend rates.

William Osborne, United States marshall of the southern district of West Virginia, was recently here in connection with the re-organization of the company that operates the Surprise, Lone Pine, and Pearl mines in the Republic district, Washington. These properties have been taken over by the West Virginia Mining Co., capitalized at $1,000,000. This is to be reduced at once to $250,000. New machinery has been shipped. About 40 men are at work at the mines. These properties have been frequently discussed in the *Press*.

The Juneau, Alaska, district is assuming increased importance for Boston traders. Alaska Juneau, now on the Boston and New York Curbs, is to be listed soon on both Exchanges.

Some talk is occasionally heard of Anaconda absorbing North Butte on a share-for-share basis. The two stocks are selling at the same level in the market. The dissolution and disappearance of Amalgamated will be the signal for many new developments of importance in the Butte district. The Amalgamated's report for 16 months has been issued.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

The new mining law passed by the Territorial Legislature and approved April 20 repeals all conflicting sections in the law of April 30, 1913. Among some of the new provisions are the following: No association placer claim shall exceed 40 acres. For every individual or association placer claim $100 worth of labor shall be performed during each calendar year, including year of location. No individual placer claim in future shall exceed 1320 ft. in length, and no association claim shall exceed in length 2640 ft. Claims may not be staked by power of attorney in future, unless that power has been recorded in the recording office of the district where the claim is staked, and before the staking of the claim. [This clause probably is the outcome of the disputes in the Chisana district in 1914, power of attorney being the deciding point.—EDITOR.] No one shall locate or cause to be located more than two placer claims for himself in any one recording district within one calendar month. Assessment work must be recorded within 90 days after the close of the calendar year in which the work was done. Otherwise the location shall be deemed abandoned.

A new wall map of Alaska has just been issued by the U. S. Geological Survey. The map is on a scale of 23.7 miles to 1 inch (1:1,500,000) and measures 55 by 82 in. It may be purchased for 80c. per copy. According to the Department of Commerce, Alaska has produced gold, fish, fur, copper, and other materials worth over $500,000,000 since 1867. A small population, now 65,000, has been responsible for this great output. Products sent to the United States from the Territory in 1914 totaled $44,000,000, while shipments to Alaska were $21,610,860. Trade with foreign countries amounted to about $1,663,000.

JUNEAU

On May 12 sinking was started at the Treadwell main shaft. It is 1878 ft. deep, and will be sunk 500 ft. more. On May 28 the Alaska Mexican, Alaska Treadwell, and Alaska United companies distributed 20c., $1, and 40c. per share respectively. It is reported that Robert A. Kinzie, formerly with the companies on Douglas island, is returning to Juneau to take charge of the Noble properties at Mt. Juneau. It is thought that the Ebner mine may be included in the consolidation proposed.

ARIZONA

GREENLEE COUNTY

The pumping plant of the Morenci Water Co. is described by W. L. Du Moulin in the April *Bulletin* of the American Society of Civil Engineers. The works are about six miles southwest of Morenci, on the Eagle river. Besides supplying water for the town, the Arizona and Detroit copper companies draw their needs from the system. The population is 6000. The mills have capacities of 3000 and 1300 tons per day, respectively. There is also a 350-ton smelter. The surrounding country is almost a desert. Water is pumped in one lift of five miles against a head of 1525 ft. The plant, which is valued at $675,000, has a capacity of 4,500,000 gal. per 24 hours.

MOHAVE COUNTY

(Special Correspondence)—A number of mining transactions involving a good amount of money have taken place lately. The largest was that of the Pioneer Consolidated Mines Co. It divided its 328 acres into four groups. The Pioneer claims were sold to Colorado people, headed by Whitney Newton. The property was examined by Howard Bancroft. The Pioneer company retains the Minneapolis, Snowball, and Harold claims. A 10-stamp mill and general equipment is on the Pioneer property included in the deal. The shaft is to be sunk from 400 to 600 ft. At 100 ft. is a 293-ft. shoot averaging $8.50 per ton; at 400 ft. is 250 ft. of $12 ore.——The Straight, Hardy, Cash Entry, Moonlight, and Sunlight claims have been acquired by F. Crosley and J. O. A. Carper of Cripple Creek, and other Colorado men. The second and third mentioned are under option.——The Last Chance, Lazy Boy, and Gray Eagle properties have been optioned to Los Angeles people. The Gilt Edge was sold to New York people.

The United Eastern Mining Co. has decided to erect a treatment plant. Seeley Mudd, of Los Angeles, is a director.

Oatman, May 18.

Last week the Amster interests closed their option on the majority of shares in the Union Basin Mining Co., which owns the Golconda zinc mine. A good smelter contract is in force.

YAVAPAI COUNTY

On May 18 the new smelter of the United Verde Copper Co. at Clarkdale was blown-in. The plant has a daily capacity of 3000 tons, double that of the old smelter nearby. The mines and works are controlled by Senator W. A. Clark. Charles W. Clark is general manager, and Robert E. Tally superintendent.

Twenty stamps, two tube-mills, concentrators, and a cyanide plant of 150-ton capacity are being erected at the Copper Chief mine. Electric power will be supplied by a line going to Jerome.

CALIFORNIA

CALAVERAS COUNTY

In addition to equipping the Calaveras mill to treat 100 tons per day, 15 tons of high-grade copper ore daily is being shipped to smelters.——At 200-ft. depth in the Nassau copper mine some rich ore was cut last week.——Rich gold ore is being extracted from the Economic at Esmeralda.——At Reynolds ferry, G. Oneto and others of Angels are driving an 1800-ft. tunnel to divert the Stanislaus river from its course. It is in 1200 ft. The dry bed will then be washed.

KERN COUNTY

According to W. M. Mills, chemist and assayer at the High School at Bakersfield, extensive tests show that platinum exists in the black sand of the upper Kern river, and in the Antrim vein of the Long Tom mine. The metal occurs as an arsenide of platinum.

NEVADA COUNTY

Seventy-five tons of machinery has arrived at the Brunswick. More is on the road. Construction includes a steel head-frame, 20-stamp mill, classifiers, and vanners. A small cyanide plant for concentrate is being considered. Dividend No. 8, of 6c. per share, equal to $24,000 will be paid by the Brunswick on June 15.——On May 21 the mill, head-frame, hoist, and other plant at the California mine was destroyed by fire. The plant will probably be rebuilt, according to the manager, G. C. Cunningham.——The Ragon Flat mine, west of Nevada City, is to be shut down indefinitely.——Work is to be resumed at the Major gravel mine in a few days. J. M. Proctor is in charge.——A carload of copper ore from a property in the Rough and Ready district has been sent to the Selby smelter. L. Williams controls the mine. A good tonnage has been opened.

PLUMAS COUNTY

The Engels Copper Mining Co., which operates in Lights

cation, near Taylorsville, has issued a report for the period ended April 30, 1915. It contains the following information:

At present there are six machine drills working in the mine. Another air compressor has been bought. A favorable diamond-drilling contract has been let. Holes are to be bored in the property now worked. Further drilling will be done later on in the Superior and other claims controlled. The capacity of the mill is to be increased during the summer.

During the first four months of 1915 the mill produced 1447 tons of concentrate. Of this 563 has reached the smelter, leaving 884 tons on hand and in transit. Early in June the latter should be at the smelter. The concentrate averages 36% copper and $5.50 per ton gold and silver.

A 75-hp. Holt caterpillar engine and three Mack trucks are used for hauling supplies and concentrate. Three 5-ton trucks are also to be used. The combined haulage should move about 40 tons of product per day.

There is plenty of water on hand for the hydro-electric plant. Spring rains promise enough for the summer.

The financial results are as follows: total debt, $104,728; value of 796 tons of dry concentrate on hand and in transit, $105 per ton, $83,575; net debt April 30, $21,153; estimated yield in May, 400 tons at $105, $42,000; operating expenses in May, $20,000; credit balance, $846.

The manager, Elmer E. Paxton, states that the company should be on a paying basis within two or three months, after setting aside money for development. Edmund Juessen and Henry Hanson have been appointed operating engineer and mill superintendent respectively.

Seneca, which is 16 miles from Greenville, and 3 miles from the Great Western Power Co.'s dam at Nevis, is the busiest district in this country at present.——Denver people, who have the Seneca Consolidated under bond, made their first payment of $20,000 this week. Machine-drills and pumps are to be ordered. Ten stamps are crushing. Twenty-five men are employed, in charge of J. J. Riley and E. E. Brandt.——All the gravel mines on the north fork of the Feather river are working. These are operated by syndicates employing from one to 15 men. The Cameron placer mine is owned by Utah people. It is one of the best on the river. A 300-ft. adit is being driven to open the channel at a lower level.——Oakland people control the Glacier.——Rich gravel is being extracted from the Scott.

San Bernardino County

At the Oro Belle mine, under option to the Tonopah Belmont company of Nevada, 12 miners have been repairing the shaft. Drifts are to be started at 600, 700, and 800 ft. Good ore is showing at 100 ft. Treatment will offer no difficulties.

Santa Clara County.

It is reported that the Pacific Chemical Co. will erect a plant at Agnew, costing $100,000 to manufacture potash. Residue from the adjoining Western Grain and Sugar Products Co. will form the source of raw material.

Shasta County

The Victor Power & Development Co., operating the Midas at Harrison gulch, has started work on its hydro-electric plant. This will replace steam power.

Siskiyou County

(Special Correspondence.)—The Rollin Mining Co., of San Francisco, has unwatered the Daggett shaft of the Black Bear mine. It is re-timbering the old workings. Near the shaft a drift has cut a 7-ft. vein. The property is equipped with a 16-stamp mill and good plant. Production will commence shortly.——Hydraulicking has been resumed at the Walker & Fippin mine, near Callahan. The property consists of a large porphyry dike, easily worked with giants. Frank Fippin is superintendent.——Several nuggets have been recovered recently from the John Peterson hydraulic mine at Eddy's gulch, on the Salmon river. The largest is valued at $250. Several others were worth from $5 to $20. John Peterson is manager.

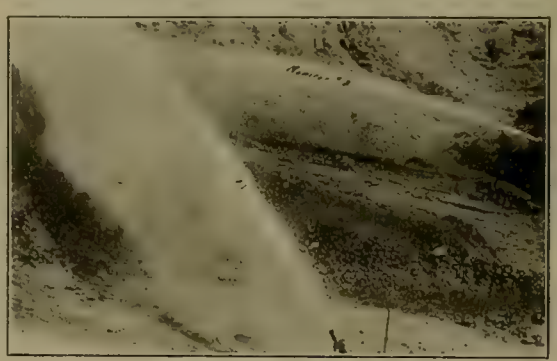
——Work has been resumed at the Homestake mine, near Yreka, with a small force. Plans are being made for the building of a small mill. Considerable ore is blocked out, together with over 300 tons on the dumps. John Boyle is superintendent. R. S. Taylor, of Yreka, is managing owner.——The Victory Gold Mines Co., composed largely of Los Angeles people, has purchased a mill for its U. S. A.-North Pole group. The plant has a capacity of 50 tons per day. Ore will be amalgamated and concentrated. It is expected to start treatment in July. John Nefroney is manager.——A large nugget, of an estimated value of $750, was recently found in the Messner mine, at Fox creek.——George Baker and sons have sluiced off the earth from their quartz claims at Indian creek and are preparing for development. Good ore has been found near the surface, and outcrops of several veins have been exposed.——The 1915 session of the Northern California-Southern Oregon Mining Congress will be held at Etna Mills, July 1 and 2. G. F. Hellmuth, M. H. Balfrey, Walter Day, E. W. Bathurst, and A. Dannenbrink constitute the committee of arrangements.

Etna Mills, May 24.

Trinity County

Five feet of ore has been opened in the Oriole mine on Indian creek. Weaverville people are interested.——A large tonnage of ore has been opened in the Democrat mine, two miles from Weaverville. Development is done by means of adits.

Recent heavy rain and a fall of snow will supply plenty of water for the season's hydraulicking. Lagrange is working full time. Trinity Consolidated is sluicing its Hupp, Union Hill, and other claims.



GIANTS AT THE LAGRANGE MINE, TRINITY COUNTY. THE INLET PIPES ARE 18-IN. DIAMETER, DISCHARGE PIPE 21½ FT. LONG, AND NOZZLE 8-IN. DIAMETER. THE HEAD IS 600 FT., AND WATER USED 2300 TO 2400 MINER'S INCHES.

Owners of the Headlight mine at Carrville plan resumption of work. The mill will probably be remodeled to treat sulphide ore in the summer.

Yuba County

A large dredge is to be built for the Marigold Gold Dredging Co. by the Union Iron Works, San Francisco. The boat will dig at Marigold, near Marysville.——Marysville people have organized the Lafayette Drift Gravel Mining Co. with a capital of $50,000. It will work a property in Plumas county.

COLORADO

Gilpin County

The Iron City mill at Black Hawk is being overhauled. Its capacity will be doubled, 50 to 100 tons per day. A large quantity of ore awaits treatment.——Fifteen lots of ore are ready to go through the Carr mill. Twelve 'cords' (9 tons per cord) of ore from the Castle Rock mine were treated last week

in this plant. It yielded 20½ oz. gold and 28 tons of concentrate.——Machine-drills are to be used in the Barnes mine, Quartz hill. J. C. Jensen is manager.——Development at the Missouri and West Baker mines is highly encouraging.

LAKE COUNTY (LEADVILLE)

The St. Louis-Colorado Mining Co. has been organized with a capital of 500,000 shares at $1 par value. The property is in the Lackawanna district, in the southwest part of the county. Work will commence early in June. Dorsey W. Almond is general manager.

An arrangement has been made between the Yak Mining, Milling & Tunnel Co. and the Big Five Operating Co. whereby the latter may drive a cross-cut adit from the Yak to the Big Four shaft. The adit will be about 700 ft. It will open the Big Four to a depth of 1000 ft. A rise will connect the adit with the shaft.

The Fortune mine, worked through the Yak tunnel, is now shipping ore to the local smelter. New machinery is to be ordered. James McNeece is in charge.

OURAY COUNTY

Rich silver ore has been opened in the Agnes vein of the Mountain Top mine. A rise on the main vein is in $20 ore. Construction of the new mill will start before long.

TELLER COUNTY (CRIPPLE CREEK)

(Special Correspondence.)—The Last Dollar mine, operated on lease and bond by Page and Rapp, will now be worked by the latter, the former having disposed of his interest to Rapp. This old mine has one of the deepest shafts here about. It was a fair producer some years ago. Its dump of 150,000 tons of $3 ore goes with the lease. A small mill may be erected to treat the dump and low-grade ore from the mine. A recent discovery on the 1200-ft. level is yielding shipments averaging around $70 per ton.

The Ajax is about to resume operations at the mine, this time on the leasing plan, probably on the 'split-check' basis. When production warrants it the mill will probably be started. Many applications for leases have been made. A considerable number of men will soon be at work.

The recent development in the Blue Bird is opening well. It now seems as though a persistent vein has been cut. In addition to the work of the company, about ten sets of lessees are at work. A fair tonnage of good-grade ore is being mined.

The Trail discovery is still causing excitement. The walls of the vein have not yet been found. Shipments are worth from $23 to $80 per ton.——The adjoining Dexter is also producing a fair tonnage of $30 ore.

Victor, May 22.

IDAHO

SHOSHONE COUNTY (COEUR D'ALENE)

Profits of all companies operating in the Coeur d'Alene in 1914 were approximately $5,981,683, according to reports to the county assessor. According to P. L. Eberhardt, of Spokane, all of the mines in the Coeur d'Alene are being worked. More men are employed than ever before. The Nine Mile district, where are the Interstate-Callahan and Success zinc mines, is the most active area. The former's two-mile aerial tramway is ready. The Marsh company is overhauling its mill. The Stanley antimony mine should be shipping ore soon. The Tuscumbia mine and Idora mill are ready. The Gertie's lower adit is half finished. Near Mullan the Silver Cable has opened a large body of high-grade zinc ore. In the Stevens Peak district the Reindeer-Queen company has a good tonnage of copper ore. A mill is under consideration. It is reported that the National copper mine and mill is to resume operation.

The Federal Mining Co. has declared its quarterly dividend of $1 per share, equal to $120,000.——The Interstate-Callahan company is to distribute an extra dividend of 75c. in addition to the regular 25c. The total will be $460,000.

Rich copper ore has been cut in No. 2 adit of the Carney mine, near Mullan. The vein is in 1500 ft., and 700 ft. below the surface. About 3000 ft. of work has been done on the property, results being encouraging.

MISSOURI

The value of the mine output of silver, copper, lead, and zinc for the year 1914 was $25,874,864, against $29,604,890 in 1913, according to the U. S. Geological Survey. The falling off was due mainly to a decrease in sphalerite concentrate of more than 36,000 tons. The production of concentrate, of which all but 40 tons was derived from the Joplin region, amounted to 189,765 tons, valued at $7,351,726, a decrease of 36,085 tons in quantity and of $1,829,234 in value, compared with 1913. The output of zinc carbonate and silicate in 1914 was 19,648 tons, valued at $415,185, against 21,531 tons, valued at $483,463, in 1913. Over one-half of this kind of zinc ore was shipped from leases of the Granby Mining & Smelting Co. at Granby. The recoverable spelter content of the zinc concentrates (which averaged slightly higher in zinc in 1914 than in 1913) was 105,994 tons in 1914, against 124,963 in 1913. The total quantity of lead concentrate produced was 279,854 tons, or 24,132 tons more than in 1913. The mines operating in the disseminated lead district in southeastern Missouri produced 249,165 tons of galena concentrates averaging 67.6% lead. The Joplin region reported the sale of 30,494 tons of galena concentrate and 195 tons of lead carbonate concentrate, a much smaller yield of both classes of ore than in 1913. The estimated total quantity of ore, lead, zinc, and copper, treated in Missouri in 1913 was 11,492,300 tons, or about 800,000 tons less than in 1913. The decrease was due almost wholly to the lessened activity in the mines in the Joplin region. The average recovery of both concentrate and metal per ton of ore treated was slightly higher than the recoveries in the two previous years, reflecting to some extent the lower ore prices prevailing in 1914, as such prices made the operation of some mines unprofitable.

The yield of silver and copper was derived mainly from the dressing of lead concentrates from mines in southeastern Missouri. The production of silver amounted to 61,168 fine ounces valued at $33,826, an increase of 25,548 oz. compared with 1913. The production of copper in 1914 was 44,463 lb., valued at $5914. The only mine in Missouri reporting production of copper ore was the Swansea mine, in Ste. Genevieve county, which produced oxidized ore carrying copper and silver.

For the week ended May 8 the output of ore in the Missouri-Kansas-Oklahoma district was valued at $639,753. This is $100,000 more than in any previous week. For the 19 weeks of 1915 the total is $5,756,200 blende, $276,445 calamine, and $709,086 lead, a total of $6,741,731.

MONTANA

FERGUS COUNTY

(Special Correspondence.)—Plans are being made for the construction of a cyanide plant at the Spotted Horse mine at Maiden in the Judith mountains. This mine has produced several millions in gold since it was discovered in 1881, having been one of the largest producers in Montana. Recently it has been profitably worked by lessees. Examination has disclosed that large bodies of ore should continue to be discovered. The ore is found in a shoot or chimney along the contact of a sheet of porphyry and sedimentary limestone and shales, ranging in age from Cambrian to Carboniferous. Some very rich pockets of gold ore have been found in the Spotted Horse, and considerable $100 ore is blocked out. The production so far has come mostly from surface workings. The mine is developed to a depth of 585 feet.

A. S. Wright, who controls several prospects in the Judith and north Moccasin mountains, has returned from the East. He will at once start development at the Gold Acres claims adjoining the New Year property. The latter at one time was considered to have excellent prospects to develop into a profitable mine. A good cyanide plant was installed and a large

amount of work was done, but the property has been closed for some time. There is a possibility that further work will be resumed there also.

The Gold Links company owns valuable ground near Kendall. The recent discovery of ore in depth at the North Moccasin mine of the Barnes-King company will result in development being done on the property in the near future.

The Cottonwood Coal Co. is now erecting a $150,000 tipple and coal-washer at its town of Lehigh, near Windham. With the completion of the washers, its product will be the cleanest in Montana. The Great Northern railroad purchases the entire production. The output will continue to increase steadily. It is mining a coal bed 8 to 14 ft. thick, from a shaft over 200 ft. deep. Last year water gave considerable trouble. Pumps recently installed have proved capable of draining the mine. There are 190 men employed at present, and 75 more will soon be added, mostly carpenters and steel-workers.

Lewiston, Montana, May 7.

Silverbow County

Two cars of ore per day are sent from the Bullwhacker to the Washoe smelter. Another car will be added soon. This will go to the East Butte's Pittsmont plant.

NEVADA

Clark County

Over 100 cars of ore per month is being shipped from the Good Springs district. Every property is being worked, including the Ninety-Nine, Monte Cristo, Frederick, Anchor (has 200 tons of 70% lead ore), Pilgrim, Whale, Sultan (has 10 ft. of zinc ore), Hoodoo, Bonanza, Prairie Flower, Dusky Bell, and Keystone. The Yellow Pine employs between 80 and 100 men. It is producing 40% zinc ore. The Boss platinum mine is still finding ore in the deeper levels. The copper ore also contains platinum.

Elko County

According to a correspondent in *The Tonopah Miner*, charges at the custom mill at Midas are far too high. The ore is not refractory. Moisture amounts to from 5 to 9%. For $20 ore the charge is $8 per ton. Every $10 increase in value another $1 is added; $1 per ton is charged for sampling and assaying. Settlements are made on 87.5% of the assay-value. Carting to the mill costs from $1 to $2.50 per ton. At Rochester, a standard rate of $6 per ton is made. There is no reason why miners in this county should not be treated as well as in Humboldt county.

Esmeralda County

During April the Goldfield Consolidated mill treated 30,872 tons of ore, yielding a profit of $154,257. Costs totaled $5.38 per ton, including 17c. for construction. Development amounted to 3205 ft., at a cost of $6.20 per foot. Lessees produced 683 tons worth $36,825. Of this the company received $18,320, less transport and treatment charges.

Humboldt County

Under the name of the Rochester Consolidated Mines Co., the Rochester Mines and Rochester Weaver companies have been consolidated. The capital is 2,000,000 shares, of which 350,000 are in the treasury. A 100-ton mill is to be erected at the Nevada-Packard mine.

Lincoln County

Investigations are being made for the new mill of the Yuba Leasing & Development Co. of Pioche. B. I. Smith is manager, and Otto Wurtenweiler will design the plant.

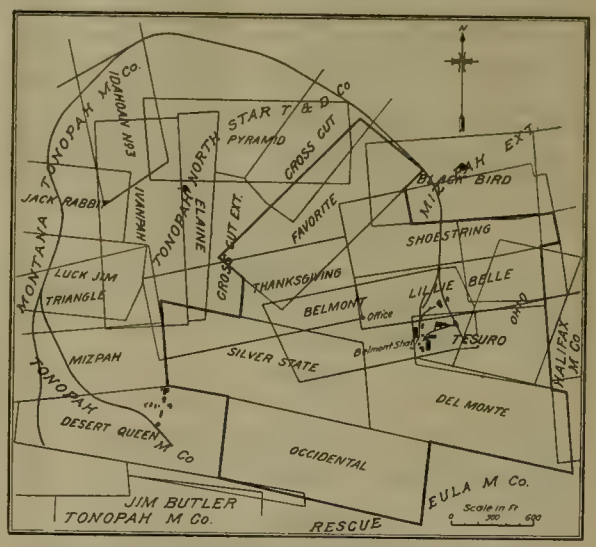
Nye County

Seven mines and lessees at Tonopah produced 10,548 tons of ore valued at $215,824 during the week ended May 22. Stope 555 in the West End is 12 to 14 ft. wide. The ore is the richest in the mine.

The report of the Tonopah Belmont Development Co. covers its financial year ended February 28, 1915. The report of the general superintendent, Frederick Bradshaw, contains the following information.

Between the 600 and 1500 ft. levels of the Belmont, development covered 24,630 ft. The total in this ground is 80,477 ft. There was no advance in the Desert Queen workings. The cost was $7.246 per foot, a decrease of 94c., and 68.3c. per ton of ore milled. There was mined a total of 228,328 tons. Of this, the 900 to 1400-ft. levels, inclusive, yielded 224,783 tons. The Belmont vein supplied 77,730; Shaft, 63,887; Occidental, 12,911; Favorite, 18,883; Mizpah fault, branch A, 4762; Mizpah fault, branch B, 14,487; Lillie Belle, 13,203; and Western, 20,585; while other veins furnished 3180 tons. From the 228,328 tons of crude ore there was sorted out 46,958 tons of waste. The latter assayed about $1.50 per ton. The resulting ore of 181,370 tons was worth about $16.74 per ton. Total mining costs were $4.313 per ton, 38.6c. less than in the previous year. Ore reserves, estimated as at March 1, 1915, consist of 226,921 tons of positive, 6355 tons of probable, and of 61,808 tons of possible ore, a total of 295,084 tons.

The mill superintendent, A. H. Jones, reported that the plant at Tonopah treated 181,424 tons of ore averaging 0.2236 oz. gold, and 22.3 oz. silver per ton. The recovery was 92.99%, slightly less than in 1913, on account of the ore being more refractory. Cost of treatment amounted to $2.564 per ton, a decrease of 48.5c. Metal production was 40,591 oz. gold, and 3,714,862 oz. silver. The plant at Millers, 12 miles from Tonopah, treated 44,692 tons of custom ore. This yielded 12,469 oz. gold, and 1,031,745 oz. silver. Profit from this work was $24,344. Costs were reduced from $4.034 to $3.766 per ton. This was the result of the new process. A saving of 80c. per ton will be made later. Extraction increased to 90.05% from 87.45%.



TONOPAH BELMONT CLAIMS SHOWN BY DARK LINES.

Like all other silver producers, the Belmont suffered from the low market price. Of the 3,714,862 oz. produced, only 2,068,763 oz. was sold. The balance is stored in San Francisco. Total receipts were $2,714,191. The net income was $1,456,698. Dividends totaled $1,462,504. At the beginning of the year the balance was $2,126,763; at the end it was $1,963,286. Quick assets are valued at $1,852,465. Dividends to date amount to $7,268,010.

The Dexter White Caps Mining Co. will hold a meeting at Tonopah on May 26 for re-organization. On March 31, cash in bank was $7.81; current assets $1106. Current liabilities were $18,827. From 1911 to 1914-15 inclusive the output was 19,909 tons valued at $381,054, an average of $19.14 per ton.

From April 1, 1906, to March 31, 1915, the net income was $45,867. Deducting $65,684, all charges, the deficit is $19,816.

The report of the Tonopah Mining Co. of Nevada for the year ended February 28, 1915, contains the following information:

Ore reserves are estimated at 102,056 tons averaging $14.94 per ton. All mining and hoisting is being done on day shift, excepting the Sand Grass work. Development amounted to 18,485 ft.; mining cost $4.10 per ton.

Changes were made in treatment. The filters did not make a satisfactory recovery of the dissolved metals. Sand did not give as good results as slime. By altering the filters their capacity was increased, and the highest recovery and lowest costs resulted. The mill treated 147,261 tons containing 2.6% moisture. It assayed 21.22 oz. silver and 0.246 oz. gold per ton. Treatment cost $2.96 per ton. Total costs were $8.51 per ton. Revenue from all sources was $2,308,740. Expenses, including $1,000,000 in dividends, totaled $2,514,473. On February 28, 1914, the surplus was $3,975,353; on that date of 1915 it was $3,860,244. Silver stored in San Francisco is valued at $609,162. The company has large interests in Colorado and Nicaragua. The former, Tonopah Placers Co., made a profit of $200,347 from dredging gold worth $467,204.

Storey County

At the Comstock lode, the Con. Virginia and Ophir, jointly with the Pumping Association, have been repairing the southwest air-way on the 1465-ft. level of the Ophir incline shaft. At 2500 ft. the station has been repaired. The main north drift from this point is to be started. In the Ophir central adit workings, the north drift shows 6 ft. of $12 ore.——At 2300, 2500, and 2700 ft. the Mexican is doing interesting work.——At 2500 ft. the Sierra Nevada and Union Con. have installed a hoist and cage at the winze station. The latter is in porphyry and quartz in the west cross-cut at 2650 ft.——The C. & C. shaft pumps are working well.——The Yellow Jacket mill received 977 tons of dump ore last week.

White Pine County

Safety First of the Nevada Consolidated Copper Co. for April shows that at Copper Flat there were nine disabling accidents, minor mishaps at the Ruth, none at the concentrating plant, and three at the smelter.

OREGON

Baker County

After being closed for 10 months the Ben Harrison has resumed work at full time; from 40 to 60 men are employed.——Good reports come from the Imperial at Cable Cove. The mill is operating again.

UTAH

The relation of ore deposits to different types of intrusive bodies in Utah is discussed by B. S. Butler in *Economic Geology* for March. He summarizes as follows: The larger intrusive bodies of Utah are of two types, laccoliths and stocks. The laccoliths occur in the sandy and shaly sediments in the southeastern part of the state, the stocks in the quartzites and limestones in the western part of the state. The stocks may be sub-divided into those truncated near the apex and those truncated at greater depth. The deeper truncated stocks are uniformly more silicious. The apically-truncated stocks are monzonitic to dioritic in composition, the deeper truncated stocks have the composition of granodiorite to granite. The ore deposits associated with the laccoliths and deeper truncated stocks have been of comparatively slight commercial importance, while associated with the apically-truncated stocks are deposits of great value.

The Murray, Midvale, and Tooele lead-silver smelters are working full blast, the first time in many years. The total daily capacity is about 6500 tons. Besides Utah ores, some comes from Colorado, California, and Montana. The smelting companies want carbonate and silicious ores. They have plenty of sulphides.

Beaver County

In the Leonora mine, Star district, 6 ft. of hematite ore has been cut in the east adit. This is promising, as silver-lead and zinc ores in the property have been associated with it. The superintendent, A. C. Nebeker, states that either gasoline or electrically-driven machinery is to be installed.

Salt Lake County

High-grade ore has been opened at 700 ft. in the Darnell claim of the Utah Apex company. The Parvenu shaft is down 1300 ft. Cross-cutting about 900 ft. for the vein has been started. The quarter ended March 31 showed a net profit of $51,106.

On April 11 the Utah Metal & Tunnel Co. cut a new orebody; one car daily is now being shipped to the Murray smelter. It contains 0.24 oz. gold, 11 oz. silver, 32% lead, 1.5% copper, and 18% iron. A large tonnage is being opened.

Three lots of ore from the Wasatch mine returned 22.42 oz. silver, 26.73% lead; 66.70 oz. silver, 11.25% lead, 11.205% copper; and 25.65 oz. silver, 6.25% copper respectively. They netted $17.70, $63.66, and $25.85 per ton. Some rich silver-copper ore was cut on May 21.——The Alta Con. is laying a 5000-ft. air-pipe from the Wasatch plant.

Summit County

The Park City Mills Co.'s plant is now in full operation, treating low-grade ore from the American Flag mine. The Holt-Dern furnace is working satisfactorily.

Washington County

It is reported in Salt Lake City that gold ore has been discovered near Quail Springs in the new Goldstrike district. An automobile road is to be constructed from St. George to Goldstrike, 33 miles. The latter place has telephone communication.

WASHINGTON

Ferry County

The West Virginia company, operating the Lone Pine and Surprise properties at Republic, is installing a 200-hp. compressor, Diesel engine, and electric hoist this month. The company has been using the San Poil compressor up to the present time. About 30 men are employed. This company is referred to in the Boston letter of this issue.

Stevens County

The first unit of the United Copper Co.'s mill at Chewelah will be ready about June 1. With the old plant the daily capacity is 200 tons. Oil flotation is part of the process. A month later the second unit should be finished. The 50 stamps will crush 350 tons per day. Diamond-drilling below 1000 ft. justifies the expenditure on plant. Costs will be reduced. Eighty-five men are employed. E. A. Wolfe and Roy Wethered are mine and mill superintendents respectively.

CANADA

British Columbia

Since sluicing started near Vernon on April 20, the Union Hydraulic company has moved 80,000 cu. yd. The ground averages 20c. per yard. Costs should not exceed 3.5c. The first clean-up will be made on June 15. R. H. Hanauer is general manager.

The report of the British Columbia Copper Co. for 1914 states that mining and smelting at Greenwood was suspended in August on account of the metal market. Development of the Copper Mountain property was continued at a reduced rate. The latter work disclosed 6,200,000 tons of 1.82% ore. Also 750,000 tons averaging 1.54%. The Mother Lode, Napoleon, Queen Victoria, and Lone Star mines yielded 178,049, 5332, 7920, and 1988 tons of ore respectively, a total of 193,289 tons. Development cost $183,204. Metal shipments realized $899,851. The year resulted in a loss of $39,765.

The general manager of the Canada Copper Corporation, Oscar Lachmund, reported as follows for 1914:

Development in the Mother Lode mine amounted to 2576 ft.,

also 4852 ft. of diamond-drilling. This work cost 8.7c. per ton of ore and $5.96 per foot, and 6.4c. per ton and $2.37 per foot respectively. Sorting cost 1.55c. per ton. The total underground charge was $6.18 per ton. Construction was charged against operation. Hand sorting increased the costs above normal. Reserves are estimated at 315,000 tons. Reserves in the Napoleon, Lone Star, and Emma amount to 273,000 tons. Prospecting was done at other claims.

The Greenwood plant smelted 299,928 tons of company and custom ore. Metals produced were 4,116,190 lb. copper, 14,442 oz. gold, and 63,501 oz. silver. The furnaces were in blast for eight months, less one week.

At Copper mountain, 130 miles west of Greenwood, prospecting consisted of 18,315 ft. of trenching (some trenches 35 ft. deep, owing to overburden), and 28,134 ft. of drilling. Estimates place the ore at 4,523,763 tons of 'reasonably assured' and 1,675,000 tons of 'probable' ore. 'Outlying' deposits contain 405,170 and 345,000 tons respectively.

ONTARIO

A winze is being sunk from the 500-ft. level of the Porcupine Crown. At 300 ft., 800 ft. from the shaft, there is 40 in. of $30 ore. The shoot on this level is 1030 ft. long. At 400 ft., 790 ft. has been opened so far. Diamond-drilling is under way at 500 ft., prospecting beyond the fault.

In April the Dome mill treated 23,630 tons of ore averaging $4.01 per ton. The annual report of the company shows that ore reserves total 2,782,811 tons assaying $4.15 per ton. These are above No. 5 level. The mill treated 248,550 tons worth $4.25 per ton. The revenue was $1,055,496; and operating profit $315,179. Net assets total $441,028.

On May 15, buildings and shaft-house at No. 1 of the Chambers-Ferland were destroyed by fire.

KOREA

(Special Correspondence.)—A recent cable to San Francisco from the Suan Concession states that an extensive ore deposit has been partly developed near the Suan mill. The superficial area is about 5,000,000 sq. ft., the depth varying from 3 to 70 ft. Metal contents are approximately 50c. gold and 1.5% copper.

San Francisco, May 12.

PHILIPPINE ISLANDS

According to 'Press Bulletin 39' of the Bureau of Science at Manila, dated March 31, the engineers of the division of mines have returned from an examination of the iron ore in Surigao province. Analyses of 250 samples will be published as soon as they are finished. Test-holes were drilled over an area of 100 square kilometres, totaling 650 metres in depth. The deposit is similar to the Mayari ore near Nipe bay, Cuba. It is a great surface blanket of iron-bearing clay, that has resulted from the weathering and decomposition of the original rock. At Surigao this rock was principally mineral serpentine. Water-power and natural harbors are near the deposit.

Schools and Societies

The SPOKANE MINING MEN'S CLUB is arranging for an automobile excursion to the Chewelah copper district in June.

Materials of engineering construction will receive special attention in the proceedings and discussions of the INTERNATIONAL ENGINEERING CONGRESS to be held in San Francisco, September 20-25, 1915.

The third annual joint field meet of the U. S. BUREAU OF MINES, AMERICAN MINE SAFETY ASSOCIATION, and CALIFORNIA METAL PRODUCERS ASSOCIATION will be held at the Panama-Pacific Exposition on September 23 and 24. First-aid and mine-rescue demonstrations will be held. Committees include well known mining men.

PERSONAL

C. W. MERRILL is at New York.

J. A. AGNEW is expected at Denver.

HORACE WINCHELL is at Salt Lake City.

JOHN M. NICOL has gone to Trinity county.

FRED. T. WILLIAMS is in northern Arizona.

ELWOOD MEAD has returned from Australia.

WILLIAM W. MEIN is returning to New York.

F. R. WEEKES, of New York, is in California.

D. C. JACKLING leaves today for Juneau, Alaska.

JAMES G. DOOLITTLE is here from Salt Lake City.

DAVID T. DAY has returned to Washington, D. C.

C. M. EYE has returned to Los Angeles from Arizona.

VICTOR G. HILLS, of Denver, was here during the week.

R. S. BAVERSTOCK has been examining a mine in Oregon.

W. S. APPLEBY has gone to British Columbia for a holiday.

J. POWER HUTCHINS has returned to Petrograd from London.

PHILIP ARGALL sails from Liverpool for New York on May 29.

S. J. WEISS has returned to London from the Malay States.

J. E. RYPINSKI has returned to Moscow, Pa., from San Mateo, Costa Rica.

R. B. BRINSMADE has been visiting the mining districts of Oaxaca, Mexico.

J. B. P. WEBSTER and WALTER G. PERKINS left London for Russia recently.

W. H. LOVELETT, A. M. PETERSON, and W. G. PATTISON are in London from the Congo.

H. V. WINCHELL has moved his office to 826 First National-Soo building, Minneapolis.

EUGENE P. KENNEDY has returned from Juneau and will remain in San Francisco for several months.

HENRY S. MUNROE was the guest of honor at a dinner given by the Chemists Club, New York, on May 28.

B. MAGNUS has resigned from the management of the Mt. Morgan mine, Queensland. A. A. BOYD is acting general manager.

CLINTON P. BERNARD was among those saved when the *Lusitania* went down. He was on his way from New York to Greenland.

SCOTT TURNER dislocated his shoulder in jumping from the *Lusitania* when she sank, and suffered minor injuries from which he is recovering.

RICHARD R. FREEMAN, JR., a Harvard graduate about to join the staff of the Russo-Asiatic Corporation in Siberia, was among those lost on the *Lusitania*.

Obituary

JOHN BIRKINBINE died at his home near Philadelphia on May 14, aged 71. He was widely known as an authority on iron enterprises and water-supply engineering. As a president of the American Institute of Mining Engineers and of the Franklin Institute, he won professional recognition of his honorable character.

JOHN TRAVERS, lately working at Johannesburg, Kern county, California, and formerly at Searchlight, Nevada, was found dead on the desert three miles from Searchlight. He had $300 about his person and was traveling with a horse and burro. From indications it is surmised that his horse got loose, that in endeavoring to catch the animal he was kicked in the forehead and then staggered forward, trying to reach help, but died before being able to attract attention. The burro came into Searchlight with the pack nearly off, and a party immediately went in search, fearing some such tragedy as had occurred, but when found the man was dead.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, May 27.

Antimony	35 —35¾
Electrolytic copper	19¼—19½
Pig lead	4.65
Quicksilver (flask)	$75.00
Spelter	16½—16¾
Tin	40 —41½
Zinc-dust, 100-kg. zinc-lined cases	20

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, May 27.—Copper is quiet and lower; lead is firm; the spelter market is excited and steadily rising.

COPPER

Prices of electrolytic in New York, in cents per pound.

The American Brass Co. has withdrawn all its quotations on brass goods made by it. This action is the result of the high prices of copper and spelter, from which brass is manufactured. Brass plants in the Connecticut valley are operating 24 hours per day. Their stocks of copper are low. Some firms are depending on day to day deliveries. The first shipment, 230,000 lb., of mineral from the White Pine mine, Michigan, has been sent to the C. & A. smelter at Hubbell.

Exports from the United States during the week ended May 18 totaled 11,869,484 lb., valued at $1,879,651. France took 4,896,631 lb.; England, 3,758,763 lb.; Italy, 2,352,693 lb.; and Norway, 578,572 pounds.

Reports for the first quarter of 1915 are as follows:

	Chino.	Nevada.	Ray.	Utah.
Ore treated, tons	406,000	564,834	656,652	1,396,341
Copper, per cent	2.1851	1.49	1.667	1.4393

The silver market is considered lifeless. On May 22 about 200,000 oz. was sent to China from San Francisco. Last week 302,219 oz. went to London via New York from Cobalt. The first quarter of 1915 shows a decrease of 1,060,647 oz. in the silver output of Ontario, which means Cobalt. London reports small supplies from America. Indian Bazaars and Europe purchases are light. Eastern exports from London to May 6 totaled £2,109,000, against £2,766,000 last year. In their letter of May 6, Samuel Montagu & Co. have interesting remarks on the situation in China. Silver stocks at Shanghai on April 10 were £8,000,000, say 80,000,000 oz. London also holds £1,000,000, say 10,000,000 oz., on China account. The War has caused this lockup of capital. It is always necessary for Eastern banks trading with China to maintain an equipoise between their commitments in gold and their commitments in silver, otherwise speculation sets in.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Tin is quiet at 37 to 38 cents.

Eastern Metal Market

New York, May 21.

A cessation of demand from both foreign and domestic consumers of copper has led to offerings at lower prices. The market remains quiet. Lead is firm, but dull. Most of the interest centres in spelter, which again is soaring because of its scarcity. Even large consumers have been buying in a hand-to-mouth manner, as evidenced by their entering the market in quest of June and July deliveries. Makers of sheet zinc and of galvanized sheets have advanced their prices. Larger arrivals and a more general acceptance of Banca tin in place of Straits has brought a decline in tin quotations. Chinese and Japanese antimony have continued to advance. Aluminum is scarce and higher.

COPPER

Both the foreign and domestic demand for copper has slackened to such an extent in the past few days that prices can be considered only nominal at best. With the lack of interest on the part of consumers there developed a growing pressure to sell, and second-hands made offerings down to 18.50c. cash, though 18.62½c. was more commonly quoted by them. Some of the producers still assert that they are holding to 18.87½c., cash, or 19c., full terms, but copper in almost any quantity can be had at the lower prices. The inactivity is believed to be but temporary. There is much talk of England having made inquiries for a large quantity, but the report lacks confirmation. Exports continue to go forward at a good rate. Up to May 21, they totaled 24,078 tons. The quotations for Lake continue to vary greatly. Choice brands are quoted at 23c., good grades can be had at 21 to 22c. Metal containing a trace of arsenic can be had at 19c. The London quotations for standard copper and for electrolytic have been irregular, generally weaker.

Comparisons and deductions of interest can be made from the accompanying table of copper exports from the United States during the four months of this year, as compiled by C. Mayer, secretary of the New York Metal Exchange. The great falling off in exports to Germany and Holland are at once apparent. It is also noticeable how far short increased exports to other countries are of compensating for the loss. The increase of shipments to Italy from 6875 tons in 1914 to 16,658 tons in 1915, and also the shipment of 8297 tons to Norway and Sweden, help to make up the deficit, but they and the other increases were not sufficient to prevent a decrease of 61,573 tons in the four months. In some minds the heavy shipments of early 1914 give rise to suspicion that buying for war needs was in active progress before the impending conflict was considered a probability by the world at large. At that time the charge was repeatedly made that the metal was being stored in Europe for speculative purposes, but today it looks different.

Copper exports in four months of 1914 and 1915, in long tons:

	1915.	1914.
United Kingdom	30,177	26,221
France	33,412	27,361
Germany	.....	51,223
Holland	237	29,059
Belgium	.....	1,683
Austria	.....	7,774
Italy	16,658	6,875
Denmark	305	.....
Norway and Sweden	8,297	.....
Russia	851	.....
China and Japan	.....	1,590
Sundries	725	449
Total	90,662	152,235

Total exports of copper from the United States in 1914 were 360,229 tons, against 382,810 tons in 1913.

TIN

Larger and more regular arrivals and liberal offerings of Banca tin at comparatively low prices have served to bring prices down until May 21, 37.87½ was quoted. A great deal of Banca tin has arrived in recent weeks and consumers, particularly those who mix metals, have been turning to it. Makers of babbitt metal, solder, and type-metal who formerly used Straits tin, have purchased Banca. Apparently they are satisfied with the results obtained. A period of dullness was broken in the latter part of last week when between 500 and 600 tons changed hands. All positions, from spot and metal afloat to tin to be shipped from the East, were dealt in. The New York quotation May 13 was 39.25c. On successive days the following prices were quoted: 38.75, 38.62½, 39, 38.25, and 37.50c. The arrivals up to May 21 totaled 2255 tons. There was afloat on that day 3880 tons. Supplies are coming in with much greater freedom from English ports. On June 3, 745 tons are due to arrive on three vessels from Singapore, Penang and Batavia.

LEAD

Despite continued quiet the market remains firm. The New York quotation is unchanged at 4.20c. At St. Louis the price has hardened, and 4.12½c. is quoted. It is reported that the United States Government has negotiations under way with a large smelter for a considerable quantity of the metal, but no large deal has been closed so far as the trade knows. This, and the fact that export sales have been lighter, are the only feature of the week.

SPELTER

It again appears as if the spelter market might be running away. Quotations have advanced steadily in the past week. The prices given for May and June metal are almost entirely nominal, because of the acute scarcity of those positions. The market has been excited, not only here, but abroad. For December delivery, up to 15.25c. has been obtained, while spot, if it can be found, will bring 16.25 to 16.75c., for prime Western. The usual differential between St. Louis and New York is more or less ignored, and practically all quotations are for prompt shipment from the West, wherever early delivery is specified. Brass mill special is selling at premiums which cannot be accurately stated, as many of them are paid following private negotiation. For high grades 20c. has been paid. Large consumers have been in the market for June and July deliveries. This indicates that their supplies on hand will not carry them far ahead. One producer states that last week he was compelled to decline to quote on 8000 tons because of his sold-up condition. The London price advanced May 18, £4, or about $19.50. The market abroad has been erratic, with alternate periods of quiet and activity. Manufacturers of sheet zinc advanced the base price of their product, May 18 to 18.50c. f.o.b. mill in carload lots. This quotation is subject to an 8% discount. Makers of galvanized sheets also have advanced their prices and the entire market for zinc and the products it enters is strong.

ANTIMONY

There is little to say about this metal, more than has been said repeatedly recently. Cookson's and Hallett's are no longer quoted, and none is offered save when some consumer wants to realize on a few odd casks he may have, and then almost absurd prices are asked. One such would-be seller wanted 53c. f.o.b., Boston, but this was an extreme case. Offers from the East are reported as fewer. Chinese and Japanese are quoted at 34.50 to 35 cents.

COMPANY REPORTS

BUTTE & SUPERIOR COPPER COMPANY

Whatever this company's name may signify, the fact remains that it is a zinc producer, one of the most important in the United States. Its operations have been followed with great interest. The report for 1914 makes good reading. The statement of the president covers the profits made, dividends paid, average price of spelter, effect of the War on the market, bonds, smelting contracts, selling arrangements, and litigation connected with the mine and mill.

During the year the property was closed for 60 days on account of necessary repairs to the main shaft. Improvements were also made to the head-frame, skips, and mill. Other equipment was installed. Development amounted to 16,796 ft. The total to date is 55,671 ft. Stoping has been done to 120 ft. above the 700-ft. level. Ore above that level is probably exhausted. Not much development was done at 800 and 900 ft. Fair results were obtained at 1000, 1200, and 1500 ft. A good shoot of average ore exists at 1500 ft. Reserves are estimated as 1,030,000 tons, averaging 20% zinc and 7 oz. silver, practically the same as in 1913. Mining cost $3.21 per ton.

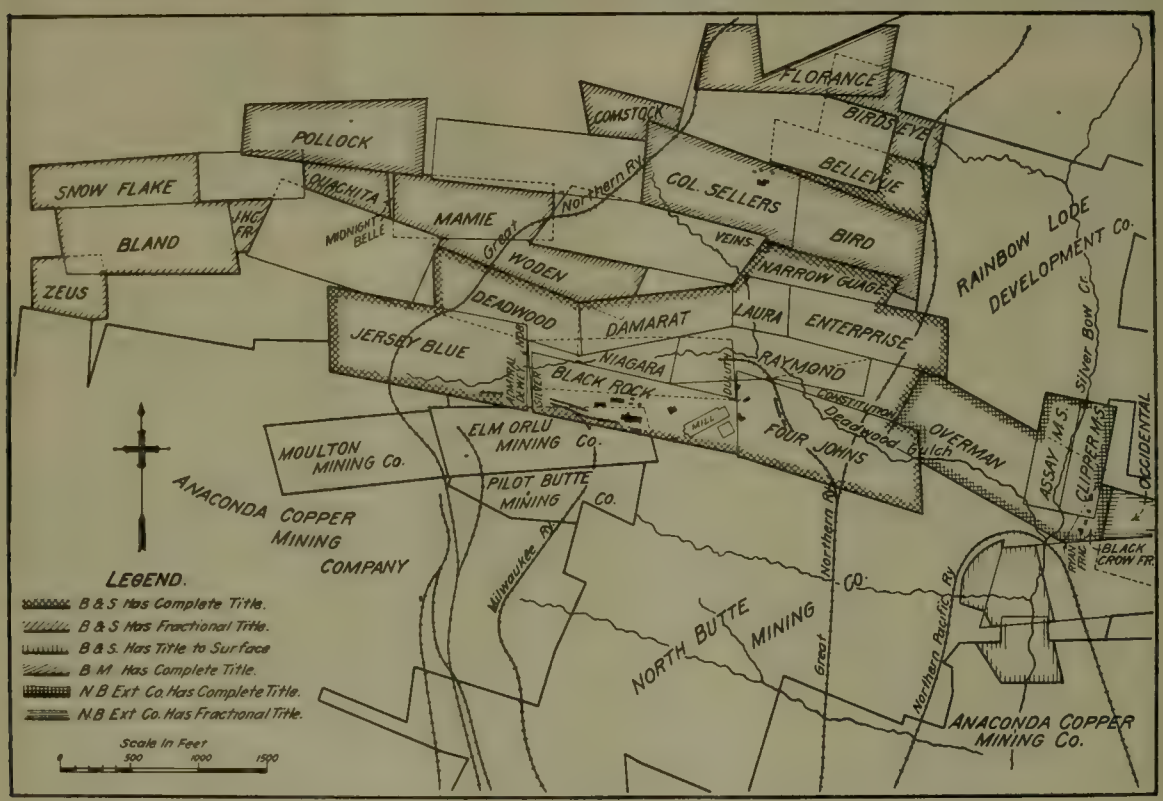
The mill treated 327,210 tons of ore, assaying 0.0196 oz. gold, 9.5315 oz. silver, 0.2105% copper, 1.3402% lead, and 18.573% zinc. The concentration and flotation plant produced 101,411 tons of zinc concentrate. This contained 5111 oz. gold, 2,578,759 oz. silver, 968,185 lb. copper, 4,941,850 lb. lead, and 107,828,679 lb. zinc. The 2972 tons of lead concentrate contained 213 oz. gold, 120,385 oz. silver, 17,708 lb. copper, 2,759,521 lb. lead, and 815,441 lb. zinc. The average recovery was 88.71%, against 86.43% in 1913. Treatment cost $2.12 per ton.

The revenue from metals was $3,238,414. All charges were $5.856 per ton. The net income was $1,417,128, against $942,988 in 1913. Dividends, $1.50 per share, totaled $611,909. The surplus at the beginning of the year was $1,215,520, at the end, $2,021,944.

AMERICAN ZINC, LEAD & SMELTING COMPANY

The report of this company for 1914 shows a profit of $186,158 before interest charges are deducted, against a loss of $91,656 in 1913, and profit of $400,300 in 1912. The net profit in 1914 was $77,692. No dividends were paid, but there is a surplus of $65,692, compared with a deficit of $394,630 in 1913. The president, H. S. Kimball, stated that the condition of the zinc industry during 1914 has been unsatisfactory. Throughout the entire year there was not a month in which the quotation for spelter at East St. Louis averaged as high as 5.5c. per pound, and the average for the year was 5.06c. He also discussed the spelter situation generally. This company's smelters have an annual capacity of 110,000 tons of concentrates, which should yield 50,000 tons of spelter, or 11% of the output of the United States. The property in Tennessee is treating 1480 tons of ore per day, and this is being increased to 1600 or 1800 tons. Plenty of ore is available. The Hillsboro smelter worked full time, the Dearing was closed, and the Caney worked at less than 20% capacity. With present conditions the company is able to make large profits.

Since the above was written the spelter market has risen considerably. This has benefited the A. Z. L. & S. Co. more than other zinc companies, on account of the results in 1914. All of its mines and smelters are working full time. At the beginning of 1915 the company was $1,000,000 in debt, and had $549,000 of bonds maturing in May.



CLAIMS OF BUTTE & SUPERIOR, BUTTE-MILWAUKEE, AND NORTH BUTTE EXTENSION COMPANIES.

BOOK REVIEWS

AMERICAN MINING LAW. By A. H. Ricketts. P. 553. Index. Panama-Pacific Exposition souvenir edition. Enlarged to May 1, 1915. Scientific Book Publishing Co., San Francisco, 1915. For sale by the *Mining and Scientific Press*. Price, $1.

The 32 chapters of this well known work contain brief abstracts of the various laws affecting mining in the United States. Seventeen pages consist of a table of several hundred cases cited under the different regulations. Recent decisions and departmental rulings appear in a chapter designated 'Continuation.'

RAILROAD FIELD MANUAL. By William G. Raymond. P. 386. Ill., index. John Wiley & Sons, Inc., New York, 1915. For sale by the *Mining and Scientific Press*. Price, $3.

Simple, compound, and vertical curves; the spiral; logarithms and trigonometric functions; location theories and tables; estimating and construction tables; turn-outs and cross-overs; azimuth, latitude, and time; tables for metric curves; miscellaneous tables; adjustment of instruments; and sexagesimal trigonometric functions comprise the 11 chapters of this work for civil engineers. The author is professor of civil engineering and dean of the college of applied science at the State University of Iowa, and experienced in railroad work. The book is for field use rather than for the office. After due consideration and consultation it was decided to use the decimal of a degree instead of minute and second. This is a new feature. Tables for solution of all problems in railroad construction are given, some not being in any other book.

MINING MANUAL AND MINING YEAR BOOK. By Walter R. Skinner. 961 pp., index. W. R. Skinner, London, 1915. For sale by the *Mining and Scientific Press*. Price, $6.

This valuable reference manual is so well known to the mining profession that it needs no review, but rather only a note to welcome its prompt annual appearance. As usual the chief feature of the book is its list of the principal mining companies of the world, 2450 being cited in this issue. For each company such details are given as the directors and other officials; date of establishment; seat of operations; description of the property, with the purchase consideration; plant erected or in course of erection; present working results; ore reserves; details of capital; assessments; dividends paid; and the financial position as disclosed by the accounts. The highest and lowest prices of the shares for the last four years is given, also the latest price. These are followed by a list of 5000 directors and 1000 secretaries of mining companies, also 900 mining and consulting engineers, mine managers, and agents. A glossary of mining terms is provided that will be helpful to those engineers and investors who speak only American and are apt to be puzzled by such terms as elvan, scrin, and swither. The present volume is especially serviceable since it shows the effect of the War upon British and other companies.

INDUSTRIAL CHEMISTRY. A manual for the student and manufacturer. Edited by Allen H. Rogers, in collaboration with 39 other chemical engineers. Second edition, revised and enlarged. 1005 pages. Illustrated. D. Van Nostrand Co., New York, 1915. For sale by the *Mining and Scientific Press*, price $5.

The first edition of this manual appeared in May 1912 and met with such a hearty reception that in preparing a second edition for the press the original chapters have not only been revised and expanded, but 10 new chapters have been added, increasing the size of the volume by 200 pages. As the book now consists of 49 chapters it would require too much space to list them, and it must suffice to say that practically the whole field of chemical technology is covered, each topic being treated by a specialist in that particular field of chemical engineering. This, of course, leads to some unevenness in treatment according to whether the author elects to write a concise review or a detailed discussion. Thus the 35 pages devoted to the petroleum industry seems modest in comparison with the 11 pages assigned to linseed oil alone, and 37 pages devoted to the essential oils. To some chapters a select bibliography of the topic is appended, and this procedure might well have been followed throughout, since it greatly increases the usefulness of a reference manual. Chemical technology is in a state of rapid progress, and the method followed of having the present status of each phase discussed by one who is on the firing-line of progress cannot be too highly recommended. The book will not only be highly useful to those engaged in the chemical industry, but as a manual of reference for the wider public which has frequent occasion to take into account present conditions in the conduct of business enterprises. It seems likely that the second edition will score an even greater success than the first, and we would recommend it to mining engineers and metallurgists who wish to keep informed of all the factors which bear on their own undertakings.

EXPLOSIVES: THEIR MANUFACTURE, PROPERTIES, TESTS, AND HISTORY. By Arthur Marshall. 623 pp. Ill. P. Blakiston's Sons & Co., Philadelphia, 1915. For sale by the *Mining and Scientific Press*. Price, $7.

No other comprehensive work on explosives has been published since Guttman's treatise of twenty years ago, although progress has been as rapid in this field as in other lines of chemical industry. The author of this volume therefore has an opportunity of which he has made good use, and the chapters dealing with the modern aspects of the manufacture and properties of explosives are excellent. Unfortunately he has introduced these with a series of chapters that might with profit have been omitted. Researches into Chinese and Egyptian history as to the invention of explosives are of interest to a few people, but most of those engaged in the industry are more concerned with the future than the past, and in any case it scarcely seems necessary to go back to the dawn of history in beginning the discussion of a subject. Descriptions of the properties and manufacture of sulphuric and nitric acids are easily accessible in standard treatises; the production of saltpeter, charcoal, and sulphur has also been amply discussed elsewhere. Fortunately the author has not relentlessly proceeded to describe the growing of cotton, the metallurgy of mercury, the manufacture of copper for caps, and similar by-ways of his subject. If such accessory material had been dismissed with a reference to the sources for detailed study, the unwieldy size of the book might have been obviated. But the painstaking effort which has led to the introduction of the material just mentioned has increased the value of the chapters dealing with topics of more imminent interest and the book is so full of useful detail that it is impossible to give any adequate summary in a brief space. It is interesting to note that although the book was written in India many of the illustrations and tables of data are taken from the publications of the U. S. Bureau of Mines, showing that the author is familiar with the world-wide aspects of his subject, in contrast with many European writers on technology, who seem to be under the impression that America is still inhabited only by savages. Appearing at a moment when the manufacture of explosives is at top speed the book should be extremely useful and should meet a cordial reception.

METALLURGICAL TREATMENT OF THE LOW-GRADE AND COMPLEX ORES OF UTAH. A preliminary report by D. A. Lyon, R. H. Bradford, S. S. Arentz, O. C. Ralston, and C. L. Larson. Technical Paper 90. P. 38. A résumé of this paper was given in the *Press* of May 8.

CONDENSATION OF GASOLINE FROM NATURAL GAS. By George A. Burrell, Frank M. Seibert, and G. G. Oberfell. Bulletin 88. 'Petroleum Technology 20.' P. 106. Ill., index. This report treats of a method of preventing some of the waste of the natural gas incidental to oil extraction. This process, the condensation of gasoline from natural gas, offers to the oil operator and others a profitable means of utilizing some of the oil-well gas now being wasted. In general, the oil-man considers casing-head gas as waste gas and its escape necessary in oil-well operations, to permit the maximum flow of oil into the well from the surrounding strata.

New Machines and Devices

Information based on letters and catalogues from manufacturers

Filters at the Exposition

Metallurgists and chemical engineers will find an interesting exhibit at the Exposition in the Oliver filter, in the U. S. Bureau of Mines co-operative metallurgical exhibit in the Mines and Metallurgy building.

This machine is the smallest of the standard Oliver products. It has a drum 3 ft. diameter by 2-ft. face, with a capacity of 10 tons per 24 hours of dry flotation concentrate. This concentrate, from the Anaconda Copper company, is fed to the filter from a 4-ft. Dorr thickener. It has a consistence of one part water to one part solid. It is discharged as a $\frac{3}{4}$-in. cake containing 6% moisture. This is carried on a belt-conveyor to an agitator, where the cake is broken up and returned to the circuit. In practice this conveyor would discharge into a briquette-machine or hopper-car. A 25 to 28-in. vacuum is maintained by a $3\frac{1}{2}$ by $3\frac{1}{2}$-in. Root rotary wet vacuum-pump manufactured by P. H. & F. M. Roots Co., Connersville, Indiana. Air at 5-lb. pressure for release of cake and agitation purposes is furnished by a rotary compressor supplied by Baker-Hansen Manufacturing Co., of Oakland, California. A 1-in. Krogh Manufacturing Co. slime pump returns the pulp from the agitator to the Dorr thickener. A total of 3 hp. is used in the exhibit furnished by five Westinghouse motors, each direct connected to the various units.

The de-watering of flotation concentrate is of such great interest to metallurgists at present that the Oliver Continuous Filter Co. is demonstrating its machine in this field rather than in cyanide filtration, where it has long been established.

The Oliver company states that over 90% of the filters in flotation plants in operation and under construction has been supplied by it.

Dredges at the Exposition

Mining men will be much interested in the two working models of the 16-ft. Yuba No. 14 dredge at the Exposition at San Francisco. One of these is in the Palace of Mines, the other in the California State building. These models are part of the Yuba Construction Co.'s exhibit. Both of them are prac-

A YUBA DREDGE AT THE EXPOSITION.

tically the same. With the exception of the fact that housing is left off, they are almost exact replicas of No. 14. This is probably the largest and certainly the most modern gold dredge in the world. It has a steel hull, steel gold-saving tables, steel deck, digs 70 ft. under water, and has a monthly capacity of 300,000 cu. yd. The model is in general to a scale of 1 to 20, although the buckets are somewhat larger, being built to the scale of 1 in. to the foot. Images of men to scale on the deck of the model dredge give a comparative idea of the great size of No. 14. Some comparative data are interesting: On No. 14 the main drive motor is 400 hp., on the model it is $\frac{1}{4}$ hp. The boat in Yuba county weighs nearly 2000 tons, whereas the model weighs 1150 lb. It would take the model dredge nearly five years to handle the material that No. 14 can excavate in one day. The Yuba Construction Co. will be glad to send a booklet describing this model to anyone interested.

A New Drill-Sharpener

The Sullivan Machinery Co. is now offering to the mining world a new drill-sharpener, which is shown in the accompanying illustration, is a compact, substantial, and convenient machine for the rapid making and sharpening of rock-drill and hammer-drill bits of all kinds, and is also adapted to the making of steel shanks. The machine consists of a heavy

THE NEW DRILL-SHARPENER.

bed or frame carrying at one end the horizontal hammer, at the other a vertical standard, which, in turn, supports the vertical hammer.

In the frame, beneath the horizontal hammer, shown in drawing, there is a 12-in. air-cylinder which supplies the power for operating the vise, which is placed just behind the vertical standard, in which the dies are placed for gripping the steel while it is being upset to form the bit.

This vise consists of a heavy cap, forming a seat for the upper half of the die, to the two ends of which are attached heavy parallel steel columns. These columns are joined at their base by a cross-head. This is connected to the heavy cross-head block of the horizontal piston-rod by a massive toggle-joint. When air is admitted on the rod side of the piston, the travel of the piston toward the rear end of the cylinder pulls up the yoke or cross-head, opening the vise, and when admitted behind the piston, the toggle is forced down against the yoke, pushing it and the columns down, and closing the vise on the drill steel with tremendous power.

The valve motion in each is of the standard differential type, but the vertical piston is kept in a raised position, when not in use, by a pin, held against the lower end of the valve by a spring, which holds the valve off its seat, thus keeping the lower end of the cylinder full of live air. This control is con-

nected with the operator's foot lever, so that pressing down upon the lever allows the spool-valve to seat and starts the hammer.

This piston and rod of the vertical hammer are in one piece, as in the rock-drill; the upper forming die is keyed to the guide-weight, which in turn is attached to the piston rod by a taper joint.

To operate the machine, the smith presses down on the handle at the front of the machine. This admits air behind the 2-in. piston of the clamping cylinder, and closes the dies and vise. Continued pressure throws the traveler in the valve-chest farther to the rear, opening the port leading to the valve-chest of the hammer, which then starts reciprocating. When the bit has been upset enough, the operator raises the handle, shutting off air to the hammer first, then admitting air in front of the clamping cylinder piston to raise the yoke and open the dies.

The piston in the upsetting hammer cylinder is a floating hammer as in the standard hammer-drill manufactured by this company. The rod terminates in the front head in an anvil, and is blank at the other to receive the loose 'dolly.'

The exhaust air is led directly into the frame, from the side opposite the valve-chest. The vertical standard is a tight box and forms a conduit for the exhaust. From this, a diagonal hole connects with cored passages arranged so as to discharge the air forcibly on the faces of the vertical dies, thus keeping them clean of scale and chips.

A powerful blast of exhaust air also blows on the dies and vise jaws, keeping them free from dirt and scale.

A blow-gun and small hose are attached to the air-piping for keeping the other parts of the machine clean. The hammer cylinders are lubricated by regular automatic, differential pressure-lubricators, cast in the cylinders.

The sharpener is fitted with safety appliances which make it 'fool proof.' The valve-motion of the horizontal members is so arranged that the vise is operated before the upsetting hammer begins to run. In order to prevent the vertical hammer from starting while the horizontal members are working, a reach-rod and pin are provided which fall in front of a stop attached to the axle of the foot lever; thus, even if the operator should step on the lever inadvertently, the vertical hammer would not be released.

To permit the changing of dies, or for work in which the vertical hammer is not needed, a hole is bored in the guide weight and guide, and a pin, attached to a chain, is furnished to lock the guide-weight, in one or the other of two positions.

An indicator or tell-tale is provided to show the operator if the toggle and vise are properly adjusted.

In addition to making and sharpening bits and forming drill-shanks, the machine may be used for a variety of smithing work, such as forging bolts, and similar work. The vertical hammer is exceedingly powerful and rapid, and at the same time can be regulated to strike as gentle a blow as may be needed.

The machine impresses one by its compactness, simplicity, and workman-like appearance, as well as by its massiveness and solidity. The main frame or standard is a very heavy casting with a broad base and is arranged to be bolted to the floor or to timbers.

The entire weight of the machine is about two tons.

In sharpening or making bits, one heat is usually sufficient to complete the work. The steel is first placed in the clamping dies and held rigidly by the vise while it is upset. After a few blows, the bit is pulled back under the vertical dies, and the wings and corners drawn out and hammered to proper thickness and shape. Then the upsetting is complete in the clamping dies and the final gauge given by the dolly. The vertical hammer puts the last touches on the wings, and the drill is ready for tempering.

In making shanks, two heats are generally necessary.

The actual time required for making a new bit from blank stock is from 50 seconds to one minute.

It is to be noted that in the operation of this machine, the sharpening process consists solely of a hammering rather than a squeezing of the steel, which is claimed to be a decided improvement over some of the older type machines. This hammering method also makes it possible to keep the steel hot for a longer time than in machines which employ a molding or squeezing process.

Commercial Paragraphs

A dredge to cost $400,000 is being constructed by the UNION IRON WORKS, San Francisco, for the Marigold Gold Dredging Co., near Marysville, California.

In an 86-page illustrated catalogue, the KENNEDY-STROH CORPORATION, 120 Broadway, New York, describes its ore milling, cyaniding, and smelting machinery. This includes from crushers to bullion furnaces.

Auto-trucks of all designs for all purposes are described in brief and illustrated in a folder issued by the STERNBERG MOTOR TRUCK Co., of West Allis, Milwaukee, Illinois. Some costs of operation are given.

The ORENSTEIN-ARTHUR KOPPEL Co., makers of industrial and portable railway material, Koppel, Pennsylvania, announces that its associate Pacific Coast manager, A. A. Prausnitz, is touring the Hawaiian islands for the firm.

In Kansas City the WESTERN ELECTRIC Co. has moved into a new warehouse, opposite its old one. It is five stories high, 50 by 175 ft. in area, 52,000 sq. ft. of floor space, is fitted with a sprinkler system and is equipped for efficient work.

The annual meeting of the JOSEPH DIXON CRUCIBLE Co. was held at Jersey City on April 19. The old board of directors was re-elected. Officers are as follows: president, George T. Smith; vice-president, George E. Long; treasurer, J. H. Schermerhorn; secretary, Harry Dailey; and assistant to last two officials, Albert Norris.

In *The Excavating Engineer* for April is an interesting article on nitrate mining in Chile, by John G. Beck. Owing to the occurrence of the *caliche*, drag-line excavators of the BUCYRUS type are useful in mining. There are also described street excavation by a Bucyrus 14-B revolving shovel, steam-shovels at stock-piles, and excavation for the Cedar River dam, Iowa. This article is a reprint from the *Press* of April 3.

Laboratory apparatus working at the U. S. Bureau of Mines booth in the Palace of Mines and Metallurgy at the Exposition consists of the following: one each of 'Braun' improved No. 1 and No. 3 improved 'Chipmunk' crushers, type 'UA' pulverizer, and sample-grinder; one sample mixer; one No. 8 furnace; two Braun muffle-furnaces; one table cupel-machine; one electrolytic outfit; one Braun universal sampler; and 'Vesta,' 'Cary,' 'Braun industrial,' 'Marvel,' 'Vulcan gas,' and 'Braun gas' burners. The above was supplied by BRAUN-KNECHT-HEIMANN Co., San Francisco.

The METALLURGIC ENGINEERING Co., of Chicago, has changed its name to that of the SNYDER ELECTRIC FURNACE Co. The company is just completing the installation of a second 3-ton furnace for the Otis Elevator Co., Buffalo, New York. This furnace will have a basic lining, and will be ssed in the manufacture of refined steel castings. Also a furnace of 6-ton daily capacity of refined steel for the Niagara Electric Steel Corporation, North Tonawanda, New York. Other installations are being made by the Snyder company. Two interesting illustrated bulletins on electric-furnace operation and steel produced have just been issued, one of which should be filed for reference on the subject.

A 4-ton furnace has been sold to the DAIMLER MOTOR CAR Co., England. This makes the fifth furnace of this company sold to European people within the last two months.

Mining and Scientific Press

ARTICLES

OPPORTUNITIES IN CHINA.
By H. T. Liang 868
The undeveloped mineral resources of China offer the same opportunities for American capital that our own once offered to European capital. A well-known mine-owner and operator in central China suggests co-operation.

THE METALLURGY OF ALLUVIAL MINING—II.
By John M. Nicol 869
To recover more gold in alluvial mining, a device is suggested which permits continuous cleaning of the riffles. To get rid of the excess of water a dewatering device is proposed. The fine material collected in the sluices is to be concentrated on tables and the magnetic particles removed by magnetic concentrators. Recent devices for improving methods are discussed.

WET METHODS OF MERCURY EXTRACTION.
By E. Bryant Thornhill 873
Wet methods of recovering mercury have so far proved unsuccessful because of their high cost. It is proposed to dissolve the cinnabar in alkaline sulphides, precipitate with zinc hydrate, and regenerate the alkaline sulphide by the H_2S produced on dissolving the HgS precipitate with sulphuric acid.

SCALE OF OPERATIONS AT BROKEN HILL, NEW SOUTH WALES. 874
The effect of the War on these companies is shown by tables.

OPERATIONS OF THE YUKON GOLD COMPANY 874
The average length of the season at Dawson was 164 days, during which the dredge worked 87.2% of the possible time, 4,800,000 yd. was handled at a cost of 27.62c. and a yield of 54.21c. per yard. Net profit for the year, including the Iditarod and California dredges, was $1,184,819; dividends were $1,050,000.

PLATINUM IN SOUTHERN NEVADA.
By Adolph Knopf 876
The discovery of platinum and its related metals in lead-copper deposits occurring in limestone in southern Nevada, opens interesting possibilities as to the finding of similar deposits elsewhere. The deposits are described in detail by one of the geologists of the United States Geological Survey.

MILLING COSTS AT GOLDFIELD CONSOLIDATED 879
Of a total labor cost of $1.606 per ton labor amounted to 21.86%, supplies 56.60%, and power 21.54%.

Direct Production of Electrolytic Copper Using G-E Apparatus

The Butte-Duluth Mining Co. is crushing, leaching, filtering and depositing copper electrolytically by a new process.

Ore heretofore considered worthless is used, and 91% of the copper in solution is recovered in 20-minute cycles. The cost of electric power is published at 36 cents per ton.

Electric apparatus furnished by the General Electric Company is used throughout the property and has proved up in every way.

Our engineers will be glad to study your power problems and recommend suitable equipment without implied obligation on your part. Send today for our new bulletins showing the application of electric power to mine problems. State whether interested in hoisting, pumping or locomotives.

EDITORIAL

T. A. RICKARD - - - - Editor THOMAS T. READ - Associate Editor

GENEROUS dividends declared by the big copper companies give expression to the favorable change in their fortunes during recent months. The distribution of profit indicates confidence on the part of the managements that the improved conditions for marketing their product is not temporary.

MERCURY, or quicksilver, to use the commercial name, is one of the metals appreciated by consumption in the manufacture of explosives employed in the War. We are able to publish a timely article, carefully written, by Mr. E. Bryant Thornhill, on a wet method of extracting mercury from its principal ore, the sulphide, cinnabar.

PLATINUM was the subject of recent discussion in these columns. We are glad to give publicity in this issue to an excellent description of the Boss Springs deposit in southern Nevada by Mr. Adolph Knopf, of the Geological Survey. The writing is a model of clear exposition. By his authoritative account of the geological environment, he will have afforded a useful guide for further exploratory work in search of this valuable metal and its equally valuable associates. It is interesting to note how one of the richest of these, the rare mineral plumbojarosite, assaying as much as $6000 per ton, looked like the ordinary 'black sand' of the placer miner. Incidentally, we note elsewhere in this issue that the Russian government will impose an export-duty of 30% on platinum from the Ural region, beginning on the 30th of the current month. This will tend to decrease shipments of the metal from the chief source of supply.

TALK of intervention in Mexico was revived on May 28 when the President, in an appeal to the Red Cross, referred to the "years of internal disturbances" that had reduced the Mexican people to the verge of starvation. At Washington it was said that our Government had become convinced of the inability of any of the contending parties to restore order. A parallel was drawn between the present position as regards Mexico and that existing immediately before intervention in Cuba 17 years ago. The President's appeal for funds and supplies to relieve the starving population in Mexico, published on May 29, synchronized with a statement sent to all the military leaders in Mexico urging a friendly solution of a problem becoming daily more acute. Undoubtedly this action by the President was stimulated by the fact that the Carranza generals had seized 600 tons of corn purchased by an international relief committee for the benefit of the Mexicans in distress, and by information concerning general conditions as collected by Mr. Du Val West, who has been making a careful investigation in Mexico for the President. At the time of our going to press, it is announced that the Government has served notice on the leaders of misrule in Mexico that unless they themselves adjust their differences, the United States will find means for restoring order in the republic. This is hoped to stimulate a rally of the best elements in the population and the formation of a coalition government, which would receive American support, including an embargo upon the supply of munitions of war to any other parties in Mexico. When next we write the position may have developed to the point of indicating whether this last effort of the President is likely to prove successful.

Marketing Low-Grade Zinc Ore

Zinc producers in Utah and Nevada are about to form an association to protect their interests, according to reports from Salt Lake City. Associations of men with a common interest can always be made to serve a useful purpose, and the proposal is therefore a commendable one; but if the principal aims of those active in bringing about the organization have been correctly reported by the daily press it may well be doubted if much can be done toward realizing them. It is said that since the price of zinc began to soar the smelters have refused to buy ore containing less than 40% zinc, and that the purpose of the organization is to enable every producer to sell all his zinc ore, including the low-grade material. Unfortunately no intimation has been made as to how this highly desirable state of affairs can be effected. The

reason why the smelters will not buy low-grade ore at the present time is as plain as a pikestaff: much more ore is available than the smelters can handle, for the high price of spelter is stimulating mining in this country to such a degree that, for example, the Australian concentrate, which ordinarily equals two-thirds of our domestic production, is being offered here without meeting much encouragement. The output of a zinc smelter depends upon the zinc content of the material smelted, since it is largely a matter of cubic capacity of the retorts. With higher-grade material the operating cost is distributed over a greater number of pounds of spelter produced and the profit correspondingly increased. With ore and concentrate offered in abundance it is only the simplest common sense to buy only the highest grade material, and it is in this way that the normal spelter output of 450,000 tons per annum in the United States has been raised to 600,000 tons, the rate at which the smelters are now operating. These, quite correctly, regard the present high price of spelter as abnormal, and are therefore making every effort to turn out as much metal as possible before the price goes down again. It is perfectly natural that producers of low-grade ore and concentrate should feel much chagrin that they are unable to sell their product during a period of high prices, but it is difficult to see what they are going to do about it, unless they have in mind the building of a smelter for themselves, a procedure that is seen to be impracticable on a moment's serious thought. Building a large smelter involves the spending of dollars in millions, not thousands, and it is necessary to be assured of a long period of profitable operation to return the capital invested before any real profit can be made. Before the War broke out the zinc-smelting capacity of the United States was considerably in excess of requirements; after peace is declared and international relations are resumed presumably the same conditions may obtain. The building of new smelters on the basis of a temporary demand therefore appears a foolish undertaking. The present high consumption of spelter is in the making of brass, therefore the ores and concentrates that are free from lead are most in demand. High-grade concentrate, such as the 51% product of the Butte & Superior is also well received; while the 46% concentrate of the Australian mines, which is also more difficult to treat, can be marketed here only in comparatively small amount. As to producers of ore and concentrate containing less than 40% zinc, we confess that we see no way in which they can hope to secure an assured market for their output under present conditions.

Speaking of zinc, we note that a bill has been introduced before the Federal Parliament of Australia to legalize the annulment of metal contracts with German firms, but this law, if passed, will affect only the mining companies registered in Australia, excluding therefore the Zinc Corporation and the Sulphide Corporation, both of which are English companies. To relieve them similar legislation is required at Westminster; and of that there is no sign. Moreover, many of the German metal agencies are in the names of companies registered in Australia and therefore entitled to legal protection. What may be the effect of the annulment of contracts with enemy-aliens remains to be proved. It is a knotty problem.

Stratton's Independence

The absorption of this property by its neighbor, the Portland, is a notable event in the history of Cripple Creek. Since W. S. Stratton located the Independence and Fourth of July claims on July 4, 1891, this bit of the earth's crust has yielded $23,500,000 besides at least $500,000 of high-grade ore that was stolen during the bonanza period; so that the total production has been fully $24,000,000. Out of this, $7,600,000 has been paid in dividends, without, however, including the profits of promoters, the gains of the tributers, or the money realized from stolen ore, making altogether at least $2,500,000 more. Finally, there is the $300,000 now received for the property from its new owners. Thus it returned about $10,500,000. The ratio of distributable profit would have been considerably larger if the mine had not been the victim of a scheme of promotion that involved a fiasco. Stratton himself was a millwright by trade; he was not much of a prospector, but a shrewd man; hence he was able to see his discovery develop into a great mine without losing his head. Fortunately for him, as the mine grew in value his valuation of it kept sufficiently ahead to prevent its sale, so that he retained possession of it until in 1899 a flamboyant promoter at Colorado Springs joined hands with an optimistic financier in London to float the mine in a company that was much over-capitalized. Under that burden the mine struggled manfully, producing a big tonnage of high-grade ore. When the bonanza had been depleted, the third stage in the history of the Independence began. This was marked by the erection of a large mill to treat the dumps at surface and the remnants of poorer ore underground. Undoubtedly this last stage of the enterprise, beginning in 1906, was the most creditable to all concerned. Anybody could have done big things with the orebodies uncovered both by Stratton and by the English company with which he made such a queer deal, but it took skill and care to extract further profit from the mine in its third phase. The fourth begins now, for the old mine will yet yield a further contribution to the world's wealth. On the whole, we conclude that Mr. Philip Argall's name will be the one most honorably linked with the record of this great mine, for he not only prolonged its productive activities but he applied a metallurgical skill to the reduction of its poorer and less docile ores that does credit to him and the profession to which he belongs. While the mine will merge its identity with the Portland, the history of which is equally remarkable, it is announced that the $300,000 in cash received from the sale will be employed to acquire a new property, in the search for which the present directorate will be advised by Mr. Argall. Thus the gold from the Independence will fructify elsewhere, giving vitality, let us hope, to a

worthy successor. Meanwhile the millions that have come out of it have been doing their work in many places, and the train of events that Stratton started on July 4, 1891, has affected men and markets far apart.

Safety in California Mines

The first public hearing to discuss the rules that the California Industrial Accident Commission has formulated to govern mining operations in this state will be held on June 11 at 10 a.m. in the offices of the Commission, 525 Market street, San Francisco. The draft of the rules to be considered has been prepared by Messrs. A. P. Anderson and G. W. Metcalfe, of the United States Smelting, Refining & Mining Co., N. S. Kelsey, manager of the Argonaut mine, and Arthur B. Foote, superintendent of the North Star mines, representing the operators, James Giambrino, secretary of Amador County Miners Union No. 135, J. C. Williams, secretary Grass Valley Miners Union No. 90, and A. M. Arandall, secretary Randsburg Miners Union No. 44, representing the mine workers; and H. M. Wolflin, representing the Industrial Accident Commission and the United States Bureau of Mines. Nowadays when unnecessary and undesirable legislation is too often forced on the public by politicians unfamiliar with the conditions governing industry, it is a pleasing novelty to have innovations formulated by those directly concerned and most familiar with actual conditions.

The rules, in their present form, provide for annual reports from mine operators to the Mine Safety Department of the Industrial Accident Commission; for the designation of agents on whom notices in connection with the rules may be served; for the keeping on hand of a supply of first-aid-to-the-injured material, and training of a first-aid corps at mines employing more than 50 men. Artificial-breathing apparatus for work in irrespirable gases, is required at mines employing more than 30 men. Mine-maps must be brought down to date yearly; fatal accidents and dangerous conditions must be reported immediately. The use of intoxicating liquor is prohibited in mines. There is a series of miscellaneous rules for underground men. These rules represent the best practices commonly found at modern mines. Boilers must be inspected, moving machinery guarded, abandoned shafts fenced, and working-shafts provided with gates. Some precaution as to sanitary conditions must be taken; good drinking-water furnished, and change-houses kept available for the men. Two mine-exits must be provided and outlets must not be covered by inflammable housing. Rules for ventilation and fire-inspection are given; also rules governing the use of lights and candles, of gasoline, oil, etc., underground. Sundry requirements are made for the elimination of rock-dust and regulations framed for the control of explosives. Rules are formulated governing hoisting operations. Telephones are required in mines, and a complete set of rules covering electrical installations are included. There is a provision that mine employees shall be made acquainted with the rules applying to them and shall agree to abide by such rules.

Suggestions and criticisms are invited from those engaged in mining, and all who can do so conveniently will do well to attend the hearing and take part in the perfecting of the regulations. It should be added that the Industrial Accident Commission is already empowered by law to make and inforce its regulations, and if operators and workers neglect to assist in devising a satisfactory set they can have no just cause of complaint later.

Exit Maranon Placers

The career of the Peru Gold Placers, Inc., which we discussed editorially in our issues of February 7 and April 11 of last year, has come to an inglorious end with the arrest of Raymond McCune, the promoter, on a charge of using the mails to defraud by the sale of $200,000 worth of stock in the enterprise. It is without jubilation that we find our first judgment of the venture completely confirmed. The whole affair has been a travesty on mining and is as regrettable as a divorce scandal involving people highly placed. It will be remembered that the persons involved in this case are Messrs. Alexis I. du Pont and John J. Raskob, of the du Pont de Nemours Powder Company; Henry H. Bowman, of the Springfield National Bank; David T. Marvel, former judge of the Delaware Supreme Court; Charles S. Miller, of Miller, Franklin & Company, efficiency engineers; Otto R. Hartman, of the Ascot Tobacco Company; William R. Basset, of Basset & Company, New York, officers and directors of the company. A number of well-known citizens of Wilmington and other cities, especially in New England, became shareholders in the enterprise, impelled by the prestige and business standing of the directors as well as by the lure of the "treasure house of the Incas."

It will be remembered that at that time we insisted that the statements made regarding the property were so incredible that they would require confirmation by an independent examination, even if made previously by an experienced and reputable engineer, while the knowledge and experience of Mr. McCune and his assistants was entirely too tenuous a thread upon which to hang such large assertions. We said then: "The whole matter as heretofore presented to the public is one of belief, not of proof. Furthermore, the basis for the belief as yet advanced is not convincing to men experienced in such matters. Indeed, capable engineers who have made examinations, and thorough ones, in the very district concerned, laugh at the claims made by the Peru Gold Placers company. We are disposed to believe that the directors are allowing their hopes to cloud their judgment, but others are not so charitable and protest that the whole matter is a thinly disguised scheme to milk the public. Certainly any director who cares for his reputation and who does not know better than to allow his name to be used as in this report, would do well to seek advice from some experienced as well as trusted friend." It may be asserted further that for a business

man of high standing, devoid of any personal knowledge of mining, to allow his name to be used to bolster an enterprise based on the report of an engineer of no standing is an exhibition of childish folly only mitigated by its frequency. The most deplorable feature of the affair is that the lesson will, probably, be lost on the public. All that will remain will be a stronger belief that mining enterprises are typically swindles. From time to time prospectors and mine-owners raise the plaint that it is unreasonably difficult to secure capital for financing mining enterprises. We submit that fiascos such as the Peru Gold Placers are among the most potent reasons why capitalists are wary of mining ventures, not because such ventures are necessarily more hazardous or less profitable than other forms of industrial enterprise, but because the meretricious romance of such schemes appears to bemuse the good sense of men ordinarily hard-headed. The one thing the banker and business man must learn is to take expert advice before he lends his name or his money to iridescent schemes.

Mt. Lassen

The volcanic activity of this mountain in northern California has caused the man in the street to wonder at one of Nature's infrequent manifestations of unrest. To the miner the eruption has suggested some connection between these superficial disturbances and those he sees recorded in the rocks into which he delves deeply in search for metallic wealth. As might be expected, the daily press has approached a scientific subject with its customary blatant ignorance and filled the minds of the public with catastrophic visions of a pseudo-scientific character. Mt. Lassen is interesting, but not alarming, except to those living on its flanks. To them, indeed, the awakening of subterranean forces long dormant has been calamitous, for their farms have been covered with 'ashes' and their water supplies choked with 'mud' emanating from the vent among the snowfields. The 'ashes,' the 'smoke,' and the 'fire' express popular notions rather than scientific facts. In childhood we learned that volcanoes were burning mountains that emitted smoke and molten rock. Less simply, they are the safety-valves for energies released by readjustments of the earth's crust, whereby the rock molten by pressure and interior heat escapes to the surface under propulsion of superheated steam. The 'smoke' is steam; the 'ash' is lava shattered by the explosive liberation of that steam; it is not the residue from cinders; and the 'fire' usually is either the reflection of molten lava—in the crater—upon the clouds of steam overhanging the orifice or it is the electric discharges originating from the intense friction caused by the passage of material hurled into the atmosphere. The 'mud' that threatens to overrun the ranches near Mt. Lassen is made by the falling of hot particles of shattered rock, the so-called 'ashes,' on the snow-banks, melting them and mingling with the resulting water. Fortunately at least one scientific account of the recent series of eruptions is available. We refer to that written by Professor Ruliff S. Holway and appearing in *The Popular Science Monthly* of March. According to this authority, Mt. Lassen is an old volcanic cone about 200 miles north of San Francisco, the summit attaining a height of 10,437 feet above the sea. It stands near the southern edge of a great Tertiary lava flow that covers portions of Oregon, Washington, Idaho, Nevada, as well as northeastern California. No precise record of its previous activities exists, but the Cinder Cone, in the same district, is believed to have emitted a flood of lava about 200 years ago, and reports extant among Indians, living in the region before the white settlers came, indicate that about 1850 Mt. Lassen itself had an eruption, similar to that which began a year ago and is still proceeding. The present outburst began on May 30, 1914; it was marked by volumes of steam, showers of fragmental rock, and the formation of a big chasm in the northwestern portions of the old crater. This chasm or vent was 400 ft. long at the end of June and is reported to have increased to 900 ft. in October last. Up to a late date no molten lava has been seen by any competent observer. The mountain happens to be in a National Forest reserve, so that it has been watched intelligently by members of the Forest Service, whose evidence has been carefully analyzed by Professor Holway, who himself ascended the mountain last week, on May 27, and reports that the bottom of the old crater has been pushed up by the pressure of lava underneath. The entire top of the peak has been changed and is now smothered under big stones, covered with dry powder and the steam-blown rock that constitutes the so-called 'ash.' Professor Holway fully recognizes the inability of science to foretell the behavior of a volcano, but he hazards the prediction that the changes now in progress will end in establishing a solfataric basin on the top of Mt. Lassen, much like the group of hot springs, boiling mud-pots, and geysers called Bumpass' Hell, a locality three miles from the peak itself. 'Geyser' is an Icelandic word for gusher, given to hot springs discharging violently at the surface, while 'solfatara' is an Italian word, derived from *solfo,* meaning sulphur. It designates the feebler phase of volcanic activity, associated with the escape of steam and other gases, including the sulphurous. Early in July, Mr. J. S. Diller, a distinguished geologist to whom this region is familiar ground, is to begin a study of Mt. Lassen's behavior. We shall await his report with keen interest. According to Professor A. S. Eakle, of the University of California, the 'ash' consists of fragments of an acid volcanic rock resembling rhyolite. Here the miner's attention will be caught, for rhyolite is a rock in which ore deposits are found not infrequently, for instance, at Tonopah. Indeed this late phase of volcanic action interests the miner by stimulating his imagination in conceiving the conditions under which the big extrusions and intrusions of igneous rock must have occurred in bygone geologic time. To those events the present violence of Mt. Lassen is of ladylike gentleness. We trust that its behavior will continue to exhibit polite restraint.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Assay of Ore Containing Metallics

The Editor:

Sir—The concentrates from the ores on the Juneau side of Gastineau channel are remarkable for the gold that is carried in metallics. While it is not so noticeable in the iron concentrate, in the galena concentrate the metallics often carry more than one-half, and occasionally as much as three-quarters of the gold of the sample.

An idea of the importance of the metallics may be conveyed by the fact that one of them weighing two or three grams from a sample of 200 grams will often contain over 100 milligrams of gold. The weight of the metallics from a 200-gram sample varies from two to about twelve grams. The gold-content does not, however, bear any strict relation to the size of the metallic particle. The amount of metallics depends largely upon the wear of machinery during crushing.

When the metallics are small, direct fusion with the addition of silica to the flux is sufficient. As the weight of the metallic increases, the fusion becomes more imperfect and necessitates the breaking up of the iron by acids before fusion, which is too slow, or by using nails and adding an excess of sulphur.

In the routine work of the assay-office a large number of these samples have to be run every day. It was to facilitate this work that I devised a special method that not only insures perfect fusion of the metallics but also simplifies the mathematical calculation.

The pulp, screened through 120-mesh, is thoroughly rolled and two charges of one-half assay-ton each are weighed out. The metallics are then placed in the pan and pulp is added to bring the total of metallic and pulp up to one-half assay-ton. In adding the pulp it is tapped from a spatula to form a cone in the pan so that any excess may be removed from the top without disturbing the metallics. All fusions are made with nail flux with the addition of one nail, and require about 35 minutes in a hot muffle. The excess of sulphur present in the pulp added is sufficient to slag all the iron except where the weight of the metallics approaches one-half assay-ton. In that case it is best to divide the metallics and make two fusions.

By adding pulp to bring the total up to one-half assay-ton it is not necessary to weigh the metallics in order to make the calculation for its equivalent weight in pulp, as that is automatically done. The weight of gold in one-half assay-ton of pulp need only be subtracted from the amount of gold obtained from the one-half assay-ton of metallics and pulp, and the remainder is the metallic gold, to be distributed over the whole sample. This weight, divided by the number of assay-tons in the total sample gives the amount to be added to the assay-value of the pulp.

Example:

		Mg. Au
½ A. T. pulp A	4.48	
B	4.52	
½ A.T. metallic and pulp		94.50
Subtract value ½ A.T. pulp		4.50
To be distributed over whole sample		90.00

	Gm.
Weight of pulp	247
1 A.T. pulp and ½ A.T. metallic and pulp	45
Total weight of sample	292 = 10 A.T.

90.00 ÷ 10 = 9.00 mg. correction of metallics

4.48
4.52
9.00

18.00 oz. per ton; value of sample = $372

The silver value may be determined in the same way. This method has been in use at Treadwell for some time and has proved satisfactory.

Quantitative Blowpipe Analysis in the Field

The Editor:

Sir—In your issue of May 8, George Delius writes on this subject. While the blowpipe, in the hands of one who knows how to use it, does very well for silver, I think it of little use for gold, on account of the small amount of material that can be treated and the exceedingly minute quantity of gold that even a fair grade of ore will yield from 100 milligrams.

One-ounce ore is very fair grade; this would contain only 0.0034 mg. of gold in 100 mg. of ore, or, in round numbers, one three-hundredths of a milligram. It is very difficult to handle and weigh a hundredth of a milligram under the most favorable circumstances, and the only safe way when it is required to make returns on exceedingly low-grade material—tailing, for example—is to take several assay-tons and combine the buttons.

Anyone who can use a pan has no trouble in finding gold in ore containing $4 to $5 per ton, and can make a close estimate of the amount. If sulphides are present, it may be necessary to roast the small residue of the panning, or if nitric acid is at hand, to heat it with that, especially if galena is present. Nitric acid or roasting

removes tellurium and leaves the gold in metallic form. The cases where gold will not show in a pan are so rare that they may be safely disregarded.

E. C. WOODWARD.

Colorado Springs, May 12.

Japan and China

The Editor:

Sir—Being an old reader of your paper, I am, perhaps, permitted to make the following friendly comment on your editorial, 'Japan and China.'

In these days when you cannot take up any paper or magazine without being reminded of the colossal struggle taking place all over the world, I always welcome the day when the *Mining and Scientific Press* makes its appearance in my mail. At least for a couple of hours I have something to read that occupies my mind without any direct reference to the War. It was only during the first weeks after the War had started that now and then, like a bomb from a Zeppelin, a contributor from the other side dropped in and told us "how the War looked at London," but fortunately the War ceased very soon to look very inviting at London to write about. Now you have published in a recent issue an editorial under the caption 'Japan and China.' This, according to its contents, ought to have been entitled 'Germany and Great Britain—China and Japan, a parallel,' and which actually is a continuation of those London letters.

Maybe many readers are greatly interested to know what London thinks about the War, but I for one would consider it a favor if you will kindly exclude in the future all one-sided references to this international catastrophe, if it were only to "let us have peace" in our technical journals on this side of the ocean, where, up to the present, thanks to our President, we have enjoyed peace. I trust you will find a little space in your journal for these lines.

KURT PIETRUSKY.

Chicago, May 12.

[We are glad to accord space to Mr. Pietrusky's views. One of the most difficult tasks in the world is the successful transfer of ideas from one mind to another, and we regret that in this instance the transfer seems to have been imperfect. There was no mention of Great Britain in the editorial in question, nor any thought of it in the mind of the writer. As to presenting the London viewpoint, it will interest Mr. Pietrusky to know that the editorial was not written by the author of the letters from London, but by the junior editor, whose knowledge of London is confined to a brief visit years ago, and who can scarcely be accused of bias toward Great Britain, being an American of Irish descent. What we attempted to make clear in our editorial was that sympathies confuse vision and obscure the fact that in international relations there are fundamental principles of right and wrong that are as coldly impersonal as a theorem in geometry. However, we appreciate the goodwill shown in Mr. Pietrusky's courteous comment, and take good note of his suggestion.—EDITOR.]

Undercurrents

The Editor:

Sir—Reading the article on undercurrent plants in your recent issue, it appears to me (though not criticizing Mr. Haley's article) that the undercurrent and the concentration of the fine sand from placer deposits is about the most neglected end of mining.

In the first place an undercurrent plant should be designed in proportion to the amount of cubic yards the plant is capable of handling and should be built so that the 'feed' can be regulated both from the main sluice and also over the tables.

I found the efficiency of recovery depended largely as to the amount of material run over the tables.

The general design I have found to be the most adaptable is to place a grizzly, as *A* in Fig. 1, at the end of the main sluice. This grizzly can be either of round or octagonal steel bars, spaced from ¼ to ⅜ inch apart and at least 12 ft. long. The grade of the grizzly should be about 1½ to 2 in. per foot. The heavy material rolls over this steeper grade and is picked up by the excess of water that is not used by the undercurrent, as is Fig. 2. The fine sediment falls into the concentrate-box and is thence fed into the long feed-box and over the different tables.

The excess water is a great asset where one has a long line of waste-boxes extending to the dump, as the whole undercurrent plant has to be placed on a firm foundation where a rise from a river could not harm it. The bottom of the concentrate-box should be lined with 16-gauge sheet-steel.

It is not necessary to go into details as to the size or dimensions of the concentrate and feed-boxes, etc., as they are governed by the amount of yardage handled.

The gravel issuing from the feed-box is regulated upon the tables, passing through a baffle-box that spreads it over the upper end of the tables evenly. These tables are 30 in. wide and 12 ft. long, similar to the tables on a dredge, and are set on a grade of 2 in. per foot, ¾ in. angle-irons are used on them, made up in 12 in. sections to the table.

The beauty of this system is that one never has to stop his entire plant to clean-up the undercurrent; simply shut the feed off from one table, clean it down, turn the feed on again and go to table No. 2, and so on. A flow-sheet of a plant of this kind would read as follows:

All material to main sluice, and after passing down main sluice, the fine through grizzly to concentrate-box, from concentrate-box to feed-box, from feed-box to the different tables.

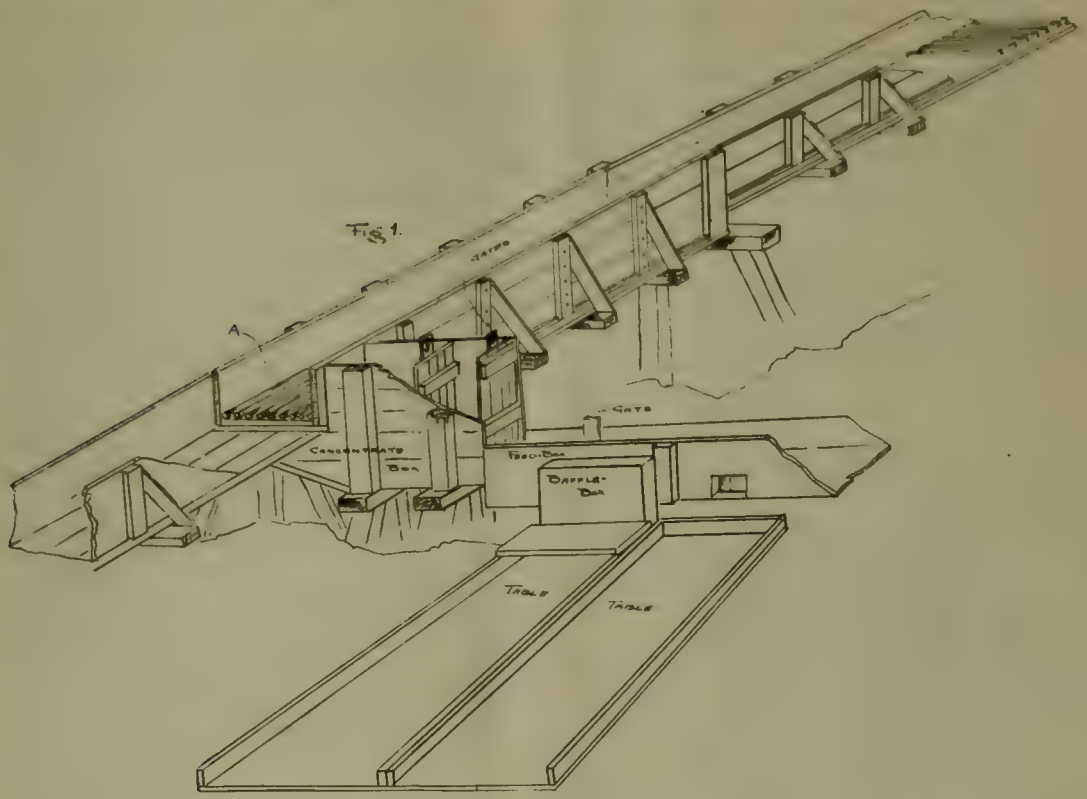
No consideration is given to block-riffles on a plant of this kind as it has been found that the tables should be cleaned-up at least once every 24 hours or more often in accordance with the yardage put through.

The idea of spilling the fine through a grizzly, over an undercurrent, without regulating the feed seems mighty poor practice.

The design of a plant is largely governed by the contour of the ground. There are times when one cannot get a gravity-flow from concentrate-box to the tables;

in a case of this kind the fine has to be elevated to the tables.

Mercury-traps can be placed at the upper end of the tables in the place of one section of riffles; where the gold is easily amalgamated, this cuts down a good deal of labor. A good concentration can be made on ordinary tables. This concentrate should be then re-concentrated over a table of special design and the product shipped to a refinery.



Pages could be written on the concentrating of placer sand and the design of undercurrent plants. I have wandered South to North in the world, and my opinion is that the average placer miner lets more gold go over his dump than is recovered in his sluice-boxes and hardly ever pays any attention to anything in his sand, except the free gold.

Seattle, May 5. B. T. Ulrich.

[The letters on this subject are most welcome. We have others ready to print. They should be read in conjunction with the thoughtful article by Mr. John M. Nicol, who shows clearly how sloppy are the conventional methods of gold-saving at placer mines. The large volume of water and the absence of classification render the effort to concentrate almost ludicrous. It is also time for alluvial miners to realize the fact that platinum and other valuable metals are usually associated with placer gold. These can be saved by some serious attempt to introduce concentration in stages. Undoubtedly, the alluvial miner, more particularly the dredge-man, has been living in a fool's paradise, deluding himself into an idea that he was making a high extraction because nobody could prove that he was not saving all the precious metal. He has been helped in his false feeling of security by the weird discrepancies between drill-hole results and shaft-sampling. These discrepancies have tended to remove the anxieties that might otherwise have filled his mind from his own inability to make his saving of gold tally with the estimates based either on drilling or shaft-sinking. Now the introduction of riffle-jigs and similar devices have already done enough to disturb the self-satisfaction of even the most complacent of those who apply water to the winning of gold.—Editor.]

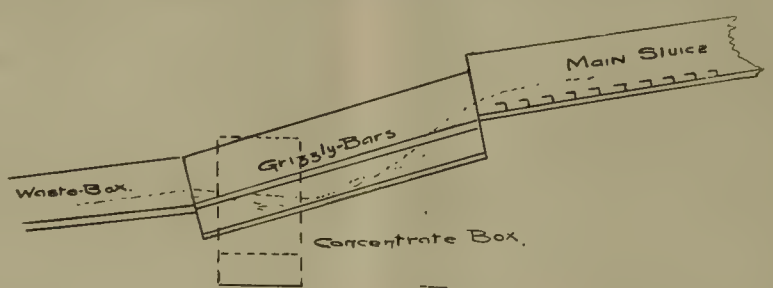


Fig. 2

Opportunities in China

By H. T. LIANG

*It seems almost a paradox to say that China is at once poor and rich. Nevertheless, it is true. China is poor, very poor, so far as hard cash is concerned, but it is rich, perhaps one of the richest countries in the world, when we begin to realize its unlimited natural resources. The natural resources of China in number and in kind will speak volumes. However, I wish to speak not so much on the general question of mining in China as on mining in Hunan, which is one of the provinces of central China.

Hunan is dotted with mines of every description: gold, silver, lead, zinc, antimony, tin, copper, iron, quicksilver, and coal. The numerous streams and canals throughout the province offer good transportation facilities. My own family was among the first to take an active interest in mining, for it has been in the business in Hunan for over twenty years.

I long had in my mind the ambition of becoming a mining engineer, and so in 1904, I came to this country for the necessary training. In the meantime, the mining of antimony at home began to assume great proportions, so that technical assistance was very much needed. In 1906, I went to the Royal School of Mines in London, and specialized in mining. Afterward, I studied under Herrenschmidt in Paris, and gained much knowledge and experience from him. The right of operating his patented smelting process in China was purchased for 100,000 francs. In 1908, upon my return to China, I at once organized an antimony mining and smelting company in Changsha, and the business has since been attended with much success. Almost all of our antimony products are imported into your great country through the office of the Wah Chang Mining Co. in New York city.

In addition, we have been operating a few lead and tin mines in Hunan, the ores of which are excellent and are easily transported to market. Nevertheless, as we are still in the experimental stage, we have not worked on a large scale. Consequently, our progress seems slow. But we have not been idle. Plans for rapid expansion have been made, and the prospect of great success seems assured. As soon as conditions in our country are a little more settled, we shall secure larger investments and more men of technical knowledge and experience for the much desired expansion.

The richness of our mines cannot be gainsaid. Let me illustrate by describing to you the Hunan Government lead mine at Shui Kou Shan, of which I have been in charge for about a year. Modern methods and machinery are used only for ore-dressing and in transporting the ores. Old Chinese methods are still being employed in breaking the rocks and in driving the drifts. Despite this fact, the mine yields high-grade lead ore amounting to about 60,000 tons per year. When we have installed up-to-date mining machinery, in a year or two, the output each year will, doubtless, increase several times. The width of the veins is over twenty metres. Foreign mining experts that have visited the place have one and all remarked that they have not seen veins of similar width at any other place in the world. This represents just one mine in Hunan, and there are many more and richer mines in the province. I hope some of you may visit Hunan in the course of time, and I shall be glad to show you what we have in the way of natural resources.

Our commission is now touring through your great country to see the notable advance which you have achieved in industry and in commerce, to seek your advice and co-operation in more than one way, and also to learn your system, methods, and spirit in transacting business. While doing this, I wish especially to investigate up-to-date mining machinery, some of which I hope to ship back to Hunan to improve and develop our mining enterprises. Further, I wish to have the privilege of conference with your leading mining men about the best mining technology, with a view to securing their best co-operation and assistance. I sincerely hope I shall have both opportunities and facilities of realizing these hopes.

The development of mining enterprise in America has been really phenomenal. It is true that your great country is rich in natural resources and you have a sufficient number of well-qualified men. But, in the early days there was one act from which your country reaped not a little benefit in developing your natural resources. That was your open invitation to capital and technical men from Europe, and they responded by coming to your country. China fully realizes the advantage of such a policy and has decided to follow your illustrious example. Already there are unmistakable indications that ere long foreign capital and foreign experts will be invited to help us in unearthing the natural resources that have been buried underground for so long.

I have made extensive trips especially through the provinces of Hunan and Yunnan and have found a number of mines which, if operated, will perhaps equal any rich mine in America. At the same time, I fully realize that without the co-operation of capitalists and mining experts from abroad, we can hardly hope to make such progress in mining as is desired and desirable. One of my great hopes in visiting America this time is to call your attention to the wonderful opportunities of mining in China today, and to urge that you do not allow them to slip. America sent invitations to financiers and mining experts in Europe and she has since profited by their response. Today China sends similar invitations to financiers and mining experts in your great country, and hopes that you will respond by coming to share with us our natural resources. Such a response will be heartily welcome, and will prove, I am sure, not only a source of great financial gain to you and to us, but also an added factor to strengthen the cordial relationship already existing between the two countries.

*An address before the Commercial Club of San Francisco.

The Metallurgy of Alluvial Mining—II

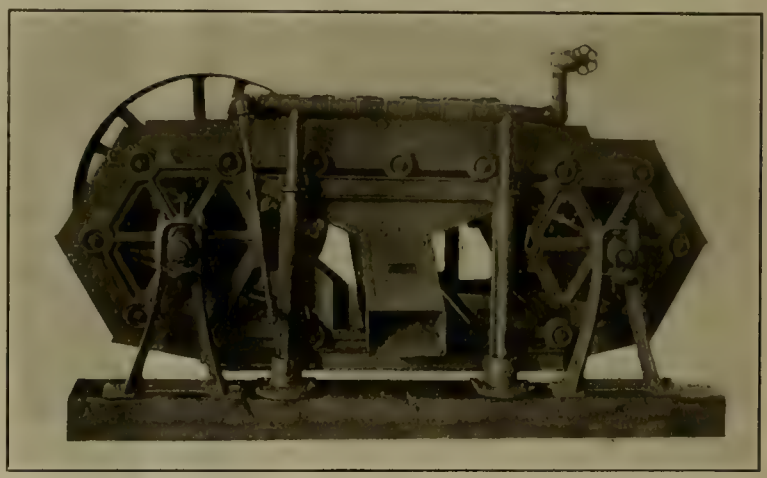
By JOHN M. NICOL

An Ideal Concentrating Plant for Placers. It is not my purpose to give the details of design of a complete plant, but, bearing in mind the principles that have been discussed in this article, to give a series of suggestions that any engineer can use and modify to meet the exigencies of any particular case, and also to describe three machines that I have designed particularly with a view to facilitating concentration work in placer mining operations.

As a rule in placer mining the available head-room for dumps is limited, and hence any metallurgical plant must be designed to use as little of this precious head-room as possible; and when head-room must be obtained for effective metallurgical operations, as small a proportion as possible of the material must be elevated to gain head.

Starting with the receiving sluice at the delivering end of mining operations, the arrangement suggested is as follows:

A short length of sluice should be built in duplicate, and the steepest admissible grade used, so that large boulders can be run through to assist in disintegration and washing. These sluices should be equipped with steel side-liners, and steel riffles having a strong boil, as in standard practice. As these sluices are in duplicate they can be cleaned-up at frequent intervals, without stopping mining operations.



A WET-SCREENING DEVICE FOR PLACERS.

At the end of these sluices a grizzly should be placed, with apertures of from ½ to ¾ inch, or even 1 in., according to local conditions. If head-room admits, the grizzly should be extra long and placed at a steep grade, so as to discharge oversize in a dewatered condition to dump, or to a stacker. If head-room does not admit of this arrangement, the grizzly must be inserted as an undercurrent, but in this case the riffles in the sluice must not be carried down close to the head of the undercurrent, preferably at least 20 ft. of smooth bottom at a lesser grade should be provided, so that the fine gold and 'heavy concentrate' have a chance to settle and travel along near the bottom, where they can be sucked through the undercurrent-grizzly. If an undercurrent-grizzly is used, the apertures will be smaller, say ¼, ⅜, or ½ inch, and if head-room is limited, the material passing through can fall into an under-pocket with side-hopper, and can be drawn off by a small hydraulic elevator or other suitable elevating appliance.

All of this undersize should then be passed over some form of 'roughing' or first-stage concentrating device, designed to catch all of the heavy material, and fitted with riffles arranged so as automatically to discharge the concentrate as fast as caught. Canvas or blanket tables, or cocoa-matting with expanded metal riffles (standard practice) fail utterly for this purpose, as the riffles do not discharge automatically and therefore rapidly choke, or else boil everything over, as already explained. I suggest the following design of machine: although it has not been tested in actual practice, it is simple and is in accord with the requirements of the case:*

The machine is to consist essentially of a large drum, say 5 to 6 ft. internal diameter, and say 20 ft. long; with open ends; the drum to be mounted on rollers and driven slowly round by outside gears. The inside would be fitted with cast-iron liners, with longitudinal angle-irons and low simple riffles spaced about 6 in. on the length of the drum. A smooth steel sluice would be suspended longitudinally down the centre of the drum. The drum would be mounted so as to be on a slight incline, and would have a free discharge-lip on the lower end and a safety-flange on the upper end. The speed of revolution would be slow, say about 4 to 6 per minute, so the power required for driving would be little.

The action would be as follows: The screened material would be fed at the upper end and discharged at the lower end of the drum. The heavy particles would settle and be caught in the riffles, which would be arranged to create the minimum of 'boil' possible. The concentrate would be caught by the longitudinal angle-

*Application for patents pending.

irons and carried around as the drum revolves, to be discharged into the smooth steel sluice, and clean riffles would be constantly presented to the flow of fine gravel and sand from the grizzly. Two or more of these drums could be mounted in parallel, according to the capacity required, and two or more in series according to the refinement of saving required.

As the sand from the undercurrents would have an excess of water, the following dewatering device could be placed between the grizzly and the drum. This device is a modification of a mill and is more or less of an improved copy of one built at the Old Channel mines in Oregon. It was used successfully for the dewatering of sand for a canvas-table sand-plant. The sketch is self-explanatory; it consists of a main sluice that receives the undersize from the grizzly or undercurrent; a cross-distribution sluice, with simple or shaped iron discharge-gates, to regulate the distribution-flow; a main spitzkasten having a hinged central baffle, with adjustable control, a series of V-shaped spigot-discharge doors; a longitudinal pipe with ascending jets and control-valve; a weir-discharge with adjustable lowering and raising edge and a discharge-sluice for the excess water and light sand. The size shown is for a mine handling a total of about 2000 yards of gravel per day.

This brings us down to the stage where we are saving everything heavy; but the volume has been reduced to probably less than 5% of the original gravel in place; hence, if the first rough concentrate contains practically all of the valuable particles, it is worth 20 times as much per cubic yard; and we can therefore afford to increase the cost of metallurgical operations to employ more refined methods for the remainder of the operations.

The material discharged from the drum-concentrator will be in a fairly dewatered condition, but will require screen-sizing to separate the coarse material, most of which will be worthless.

The coarse material could be passed conveniently over a conveyor picking-belt, to save occasional gems, lumps of cassiterite, and other minerals found in placers. What will be found is unknown until a plant of this kind has been tried, and will vary in every district. If this coarse material proved to be worthless, the conveyor could be arranged as a stacker, or used to return this material to the main sluice. If, on the contrary, it showed value by assay in included gold and platinum (which is highly probable), it could be crushed and the fine sent to the concentrating plant.

The successful screening of the great mass of mixed coarse and fine material resulting from placer mining is a difficult problem. Trommels are all right down to ¼-in. size with steel plates. But when a 20-mesh or finer screen is used, and coarse material has to be fed, the wear and tear and blinding of the screens is excessive. Bumping screens also failed. The most effective device that I have found so far consisted of a series of tray-screens linked together and forming a screening pan-conveyor. This admitted of the material being washed through the screen by jets. The distribution of the material in a thin sheet gave abundance of screening area, and avoidance of attrition on the screen-surface. Coarse wire could be used even with a comparatively fine mesh, insuring longer life.

The capacity varies, of course, but I should judge that a machine 3 ft. wide by 16 ft. long will screen about 300 tons per day to 20 mesh. This machine is not patented and any engineer is welcome to use the design or any modification of it to suit his own requirements. I designed and built the first machine about nine years ago.

The size of the screens used will depend, of course, on actual tests at the mine; it may be necessary to use two or more machines tandem, and send the different size products to different concentrators.

A number of preliminary experiments have been made, using table-machines to treat the fine from placers, and no doubt they could be used with success after a 'roughing down' process such as I have described. Their defect for this class of work is the high first cost in relation to capacity, and their lack of devices for making positive separations of four or five different products, such as is required in placer-mining operations. In view of this I designed a concentrator, which no doubt will be useful elsewhere, but was especially intended for concentration-separation work in handling the fine in placer mining. Patents were recently granted and although I have not had the opportunity to build and test a machine, I believe a description will not be amiss, and may interest those who have problems of this nature to face.

The machine consists of a traveling belt, moving at right angles to the direction of the flow of the sand. The sand is fed onto the upper edge and discharged at the lower edge. The belt travels on rollers, mounted on a frame, which in turn is mounted on rocking arms, the whole equipped with an oscillating mechanism much the same as an ordinary belt-machine. The surface of the belt is equipped with five or more flexible continuous riffles, supported by 'guide-flows' that admit of the adjustment of the height of the riffle at any part of the table.

The main feature, which gives great capacity, is that the surface of the table is moving continuously at right angles to the direction of the flow of the sand, and the concentrate is being discharged as fast as caught. The refinement of separation is due to the fact that the movement causing removal of the concentrate is independent of the oscillating movement causing settlement, and also that the height of the riffles is adjustable. These factors do not exist on other machines.

Whatever machine may be adopted, the fine material from the screens should be concentrated on some form of table or belt-concentrator, in which the riffles are being automatically cleaned. Judging by my own experience in such experiments as I have made, the resulting fine concentrate will probably arrange itself in bands, in something like the following order:

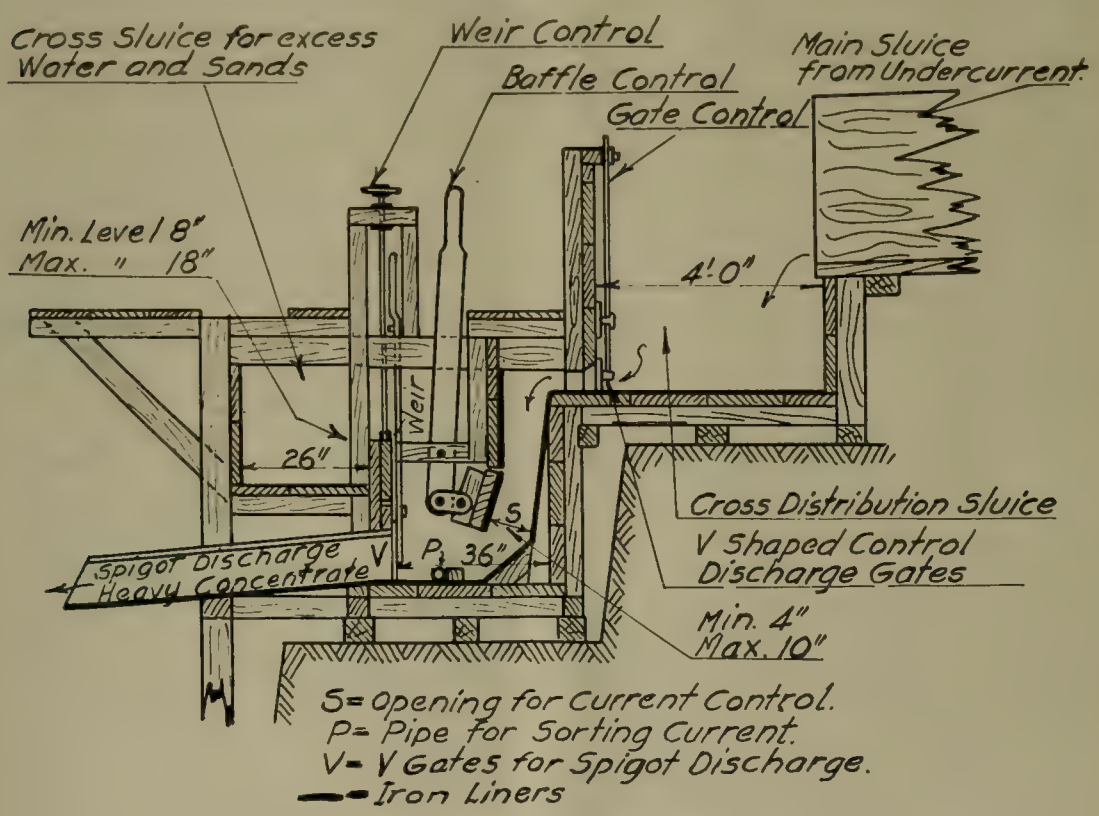
A band of very fine heavy magnetic black sand on the upper edge, or first riffle-discharge, according to the type of machine; this band will contain, in 'associated' par-

ticles practically all of the free gold, platinum, and iridosmium, and also the mercury and amalgam. It will merge into a lower band of coarser black sand, through which will be spotted particles of hematite and chromite, when these occur as gold-bearing particles; at some mines these grains are entirely absent. On the lower edge of this band and intermingled with what we might term the middling, fragments of heavy copper ores, cassiterite, and cinnabar will lie; also josephinite and occasionally wolframite. About this zone there is often a strong belt of garnet and other inferior gems, and many of the rare minerals.

It is my belief that in some districts surprising results

bunches, so that 'robbery' occurs by inclusion in these bunches. About eight years ago I tried a number of experiments with rather crude laboratory appliances, and tried to overcome this by 'free-falling' in air, 'pulsating waves,' 'varying intensities,' etc.; but I could not gain much improvement over the work done by standard machines on the market. I came to the conclusion that the defect inherent to all of them is that the magnetizable particles are drawn together on converging lines of force; hence in a fine material of high permeability this robbery by 'bunch inclusion' is bound to occur.

About six years ago my attention was drawn to some experimental work on these lines conducted by Dr.



DEWATERING SLUICE FOR PLACER MINING.

will be obtained, in regard to the quantity and value of the by-products, if a properly designed plant is used to save them; while in others only a mass of black sand with a little associated fine gold would be obtained.

Whatever is saved, it is certain that the largest bulk will be magnetic black sand, and as this is at present practically worthless and only interferes with the final separation of the gold and platinum and of any other possible by-products, our next step will be the drying of the various concentrates, followed by treatment in magnetic separators.

The question of magnetic separation of this very fine black sand of high magnetic permeability is serious, for the reason that it bunches together with intense attraction, and non-magnetic particles are picked up in the

Heintz for the Oro del Norte Co. in which he used a diamagnetic alloy, and inserted a plate of this between the electro-magnet and the sand to be treated, the effect being that the magnetic particles traveled along diverging, instead of converging, lines, so that there was no robbery by inclusion in bunches. This appealed to me strongly, but as at that time claims for patents were made and there was a certain reserve in the matter, I did not care to go further.

It appears to me that all that is required is to work out the mechanical details of a machine using this principle to get an almost perfect magnetic separation for fine black sand; but it will require knowledge of mechanical design and of other branches of magnetic separation, backed by sufficient capital.

Up to this point we have been treading on fairly safe ground, and the analysis made and suggestions given, although no doubt open to criticism, are based on the results of practical observation. But from the stage of fine concentration onward, it must be purely a case of experiment and abstract suggestion, for the simple reason that so far as I know no continuous-action concentrating plant has ever been tried at a placer mine, and therefore the products as coming from normal conditions of mining have not been available. We have no real idea as to the amount, proportion, or value. Hence my further suggestions must be taken for what they are worth.

The first narrow streak of concentrate that is cut out separately will probably be found to be so rich and so reduced in quantity that it will be a simple matter to extract the gold and platinum. Any of the following may be considered: wind separation, magnetic separation, leaching of the iron followed by amalgamation of residue, sodium amalgam when there is platinum (see Bulletin on Black Sands by David T. Day, page 62), grinding in small pans. For the hematite and chromite, if cut out separately, magnetic separation of black sand, fine grinding, and hand amalgamation of residue may be adopted. Direct crucible smelting, with lead as a carrier, is also effective for either of these products. For the streak carrying garnet and other minerals, I suggest magnetic separation, followed by wind separation of residue, and possibly use of greased plates or electrostatic separation.

These latter suggestions sound costly and complex, but as a matter of fact they all lend themselves to small-stage operations, and although the original bulk of gravel mined may be thousands of tons per day, the volume of fine product to be treated would only be a few tons per day, of material possibly worth many dollars per ton.

Recent Devices for Saving Gold. Practically all of the gold-saving devices that have been advertised within the last ten years, and all of the experiments conducted at the large placer mines, have been on routine lines, always employing fixed riffles and merely aiming at improvements in the 'boil' or in the shape of riffles, position of tables, screen, etc. A notable diversion has been the work of Charles Janin and J. W. Neill (see *Mining and Scientific Press*, November 7 and 28, 1914). The application of jigs to the saving of gold on dredges is of particular interest in that it is the first instance of any attempt being made at the continuous removal of the concentrate; although apparently no attempt has been made to save coarse concentrate or 'included value' or possible by-products.

In an editorial on page 710 of the *Mining and Scientific Press*, November 7, 1914, referring to the dredgemaster's estimate of his losses, the following remark is made: "Incidentally he is fortified in his conclusion that the metallurgical work of the dredge is well done by the fact that adding plates and tables improves recovery little. The great bulk of the gold is saved, as Mr. Janin shows, on the first few feet of tables."

If we refer to the tables of tests on page 721 of the same issue we note that the great variation in percentage saved, in relation to the continued value as indicated by the drill-tests, shows the impossibility of accurate sampling, which is a proof of the erroneous conclusion that may be drawn regarding the efficiency of the gold-saving appliance of a dredge, if the recovery is based on the relation of samples of heading and tailing.

The argument, so frequently put forward, that the high percentage (of the total saved) that is extracted on the first few tables is a proof that the losses are negligible, appears to be a fallacy. It really only proves that certain gold that is easy to catch settles quickly; and overlooks the fact that a piece of gold that boils out of the first two or three riffles will probably boil out of the tenth riffle; and it entirely overlooks the possible value of 'included' gold or by-products.

Mr. Janin's work shows a fairly big average recovery, and is probably of as high a grade of work as any done today; and the methods of sampling are as perfect as the present methods of the art permit; but still all the work is based on the sampling of 'free gold.' There is no doubt that the 'black sand' rarely contains 'included values,' it is only an associate of the free gold. Again, in the gravel deposits of the flat flood-plains exploited by dredging the proportion found of other mineral particles, likely to carry 'included' gold, is probably very small in comparison to old-channel gravels in the mountains and nearer to the source of the gold and minerals.

The jigs, no doubt, will help, especially in dredging where space is limited, but they will fail in saving all of the coarse concentrate, and herein lies the possibility of future development.

Another attempt out of the routine, to which my attention was recently drawn, is a shaking table, designed by J. B. Giffen, which was used successfully at Manhattan, Nevada. This was a shallow placer where water was scarce; the table was 8 ft. long by 32 in. wide, and had 64 inches of riffled surface, it handled successfully 40 cu. yd. of roughly screened gravel in 8 hours, using only 9 gal. of fresh clean water per minute; the tailing went to a settling-pond, and the water was pumped back for use. The operators claim that they saved 90% of the gold, and also a small amount of platinum. Another of these machines is operating successfully, treating the tailing from a small undercurrent in a mine on the Klamath river, in Oregon. The operators claim that they saved $2 per hour from tailing that was declared to have not a trace of gold, as proved by ordinary pan and rocker tests.

Another useful little machine is the Dibert gold-extractor, designed for beach-sand, and mining on a small hand-scale. It consists of a hopper, a vibrating screen, and a steeply inclined riffled-tray. This machine would appear to be useful for testing large samples.

Both of the above machines, while useful and no doubt effective for a particular class of work, do not fill all of the requirements needed to solve the problem; in fact, there is no machine on the market today that will do so.

What we require is a plant that will save everything heavy, including the coarse concentrate, and then make the final separation of gold, platinum, etc., in stages.

Wet Method of Mercury Extraction

By E. BRYANT THORNHILL

Little has been done in recent years on the metallurgy of mercury except in improving the furnaces for distillation and the condensers. G. V. Northey used water concentration at the Manzanita mine for some time and reports success. Clifford G. Dennis recently made some tests on floating the cinnabar and got good results, considering the crude apparatus used. The small profits of the business, however, except to those having high-grade ore, have not been conducive to experiments involving any radical change in the treatment of ores. The present high price of the metal, due to its use in making explosives, has stimulated the industry to an extent not seen in years. Practically all foreign competition has been shut off and American producers are getting almost any price they demand.

At present, two methods are in use to obtain mercury from its ores on a large scale. One depends on the fact that at a high temperature the oxygen of the air combines with the sulphur of the mercuric sulphide, forming sulphur dioxide and metallic mercury. The other depends upon heating the mercuric sulphide with iron or lime, the sulphur combining with the iron or lime, setting the mercury free. The first method is carried out in shaft-furnaces, usually of the continuous type, and is the more important of the two commercially. The second method is applied in retorts and is too expensive a procedure except for rich ores.

In spite of its universal application, the furnace method has disadvantages that will never be overcome. These are high cost of installation, quantity of soot caught with the mercury in the condensers, imperfect condensation, low extraction, particularly on low-grade ores, poisoning of workmen, excessive amount of mercury tied up in condensers, and the time required to place mercury on the market after the plant is put into operation.

The cost of building a continuous furnace of the type most used in California is approximately $1000 per ton of capacity. This figure would be excessive in some cases and low in others, but represents the average cost. On low-grade ores, 0.5% or lower, the soot caught with the mercury in the condensers usually necessitates retorting the product. The brick-work of the condensers absorbs mercury, and furnaces have been known to run from eight months to one year before any clean-up could be made. The actual investment in a furnace plant would not only be the installation cost of $1000 per ton of capacity, but would include operating costs until mercury could be placed on the market.

To those considering the installation of a furnace plant, to take advantage of the present high prices, the time required to put the mercury on the market is of especial importance.

These disadvantages led C. A. Mulholland to experiment with a hope of devising a wet process for the extraction of mercury, particularly from low-grade ores. It has long been known that mercuric sulphide is soluble in alkaline sulphides containing free alkaline hydrate, and Becker, in his monograph, 'Geology of the Quicksilver Deposits of the Pacific Coast,' made elaborate experiments to prove that the California deposits were due to the dissolving and subsequent precipitation of cinnabar from such solutions. The scheme of treatment suggested by Mulholland, deduced from his experiments, was to grind the ore in an alkaline sulphide solution, whereby the cinnabar was dissolved, separating the solution from the ore by filtration or decantation, precipitating the mercury out of solution with zinc hydrate, which brought down a mixture of zinc sulphide and mercuric sulphide, dissolving the zinc sulphide out of the precitate with sulphuric acid, and retorting the remaining precipitate of mercuric sulphide to obtain metallic mercury. The hydrogen sulphide formed by dissolving the zinc sulphide was used to regenerate the sodium sulphide solution. The chemical reactions involved in Mulholland's scheme are:

$$Na_2S + HgS = Na_2S \cdot HgS$$

$$ZnSO_4 + 2NaOH = Zn(OH)_2 + Na_2SO_4$$

$$Zn(OH)_2 + 2NaOH = Na_2ZnO_2 + 2H_2O$$

$$Na_2S \cdot HgS + Na_2ZnO_2 + 2H_2O = HgS + ZnS + 4NaOH$$

$$ZnS + H_2SO_4 = ZnSO_4 + H_2S$$

$$2NaOH + H_2S = Na_2S + 2H_2O$$

The sodium sulphide solution was destroyed each time it went to precipitation and was regenerated by introducing the hydrogen sulphide formed when dissolving the zinc sulphide with sulphuric acid. The mercury was obtained from solution as the sulphide and was retorted with lime or iron.

Where the cost of mining is low, Mulholland estimated that mercury ores as poor as 0.3% could be worked at a profit by this process. No commercial application of this process has ever been made, to my knowledge.

The Buffalo Mines, at Cobalt, of which T. R. Jones is general manager, is at the present time using a wet method to recover mercury as sulphide from amalgamation tailing. This should be equally applicable to cinnabar ores. The mercuric sulphide is dissolved out of the tailing with sodium sulphide and the mercury precipitated on scrap aluminum. The chemical equations are

$$Na_2S + HgS = Na_2S \cdot HgS$$

$$3Na_2S \cdot HgS + 8NaOH + 2Al = 3Hg + 6Na_2S + 2NaAlO_2 + 4H_2O$$

$$2NaAlO_2 + Ca(OH)_2 = 2NaOH + Ca(AlO_2)_2$$

From the equation, 11 lb. mercury should be pre-

cipitated with 1 lb. aluminum. Practically the ratio is about 7 : 1, as some hydrogen is given off during the precipitation. Not only is the sodium sulphide combined with the mercuric sulphide regenerated, but the sulphur with the mercuric sulphide goes to form sodium sulphide. The caustic soda is regenerated by the addition of lime, which also assists settling or filtration. These points have all been verified by laboratory experiment and actual practice. With a clean cinnabar ore the mercury would be obtained wholly in the fluid form without retorting, and by straining through canvas it would be made ready for market.

Over 40,000 lb. mercury has been recovered by the Buffalo Mines by this process at a cost of approximately 13c. per pound. The applicability of the process to cinnabar ores cannot be questioned, both as regards cost and recovery, and it should obviate most of the difficulties inherent in the distillation method. The cost of installation should not exceed $500 per ton of capacity. Since standard cyanide machinery can be used: crushers, pebble mills, Dorr classifiers, thickeners, etc., the plant could be erected in a minimum of time and mercury could be placed on the market in three to four days after the plant was put in operation.

The mercury produced at the Buffalo Mines by this process was assayed by Ledoux & Co., who reported silver only in determinable quantities. The sodium sulphide used costs $1.25 per cwt. f.o.b. chemical works for the commercial crystals and the aluminum for precipitation consists of casting-foundry turnings costing $2.50 per cwt. f.o.b. foundry.

Scale of Operations at Broken Hill, New South Wales

How the war has affected Broken Hill is well shown by the following table of output for the first and second six months of 1914:

	Jan.-July. Tons.	July-Dec. Tons.
South	172,000	111,891
North	156,000	104,755
Proprietary	153,000	121,316
British	110,000	27,218
Central	107,000	73,321
South Blocks	87,000	54,376
Block 10	48,000	37,853
Junction North	46,000	9,848
Junction	10,000	.....
Block 14 (sulphides)	18,000	.....
Block 14 (carbonates)	6,000	9,058
Totals	913,000	549,636

The mines producing are as follows, according to the *Mining Standard*: Proprietary, Central, Zinc Corporation, South, North, and Block 14 (the latter on a small scale). The non-producers are Block 10, British, Junction North, and Junction. During the last half of 1914 Amalgamated Zinc produced 45,286 tons of zinc concentrate from 165,448 tons tailing. None of the product could be sold.

Operations of the Yukon Gold Company

The Yukon Gold Co. operates dredges near Dawson, in the Yukon, at Iditarod in Alaska, and at Oroville in California. It also conducts hydraulic operations near Dawson. The report of the general manager, O. B. Perry, for 1914, contains the following information:

The eight Dawson dredges worked from May 12 to October 23. This was about 20 days shorter than the previous season, due largely to the discontinuance of the use of purchased power. The dredging season is now limited in length by the operation of the company's hydro-electric power-plant, which, owing to climatic conditions, has water available only from May 10 to October 20, approximately.

The average length of the dredging season was 164 days, during which the dredges operated 87.2% of the possible time. They mined 4,800,781 cu. yd., yielding $2,602,685, or an average of 54.21c. per yard. The cost, including depreciation, was 27.62c. per yard. This is about 2c. lower than last season. The results, compared with 1913, show a decrease in yardage, gross value, and net profit. The first was due to the shorter period of operation; the second followed from the decrease in yardage; also there was a reduction in value of 10.92c. per yard. Less high-grade ground was dredged than the season before, the depth of tailing handled being greater, which reduced the value of the ground. The total cost was less than the previous season by $189,792. Royalties paid to owners were $111,107 less.

While the total yardage was smaller than in 1913, the average duty of the dredges was higher for the operating time. This was due in a large measure to the excellent power service maintained by the company's plant. The thawing cost was reduced 1.39c. per yard. It was lower than for any previous season since operation commenced. During the season a total of 421,835 sq. yd., or 68.6% of the ground handled, was frozen and had to be thawed by steam.

The Iditarod dredge commenced operations May 4 and stopped for the winter on November 11. The boat handled 668,737 cu. yd. This produced $739,631, an average of $1.10½ per cubic yard. The total operating cost, including a depreciation charge of $50,000, was $335,825, or 50.2c. per yard. This is a decrease of 14.1c. compared with the previous year. The operating season was 191 days, during which the dredge ran 4210 hours, or 91.91% of the possible time. In general, the boat was operated under more favorable conditions than the previous season. The maximum grade of the creek did not exceed 5%. Few boulders were encountered. Although large quantities of granitic sand were handled, the disposal of this was not a serious problem. During the season 67,260 sq. yd., or 74% of the total area, was thawed by steam.

The three California dredges, operated by the Pacific company, dug 3,198,192 cu. yd., yielding $322,571, at a

cost of $136,772. The average cost of the dredging operations was 4.27c. per yard, including depreciation. The dredge on Butte creek began work on October 3, so that only three months are included in these figures.

A total of 3,241,641 cu. yd. was moved at the hydraulic mines. This produced $544,262, at a cost of $245,686. The working cost was 7.6c. per yard, exclusive of depreciation of the main ditch, a decrease of 2.1c. compared with 1913. The total water used amounted to 519,834 miner's inches, compared with 406,135 in 1913, a gain of over 25%. The duty of the water was 6.02 cu. yd. per inch.

The Twelve-Mile water system was operated from May 8 to September 30, inclusive, a total of 146 days. The average daily delivery was 3561 miner's inches. The ditch was operated for 96.4% of the possible time. Severe frosts early in September caused considerable difficulty in keeping the ditch open, otherwise the system gave excellent service.

Leases on claims owned by the company in the Yukon and Iditarod carried under the head of 'lay operations,' yielded a total of $135,897, at a cost of $6525. As mentioned in the last report, expired leases, where they are in line of dredging, have not been renewed.

All operations yielded gold worth $4,345,046. Operating charges totaled $2,050,889. The net profit was $1,184,819. Dividends amounted to $1,050,000.

The "lay operations" mentioned in this report refers to an important feature of mining in the North. Small parties or partnerships of working miners will take a lease or 'lay' on an alluvial claim, paying the owner a royalty up to 50% on the gross output. For this rich tribute the claim-holder may have done nothing beyond locating the ground or having it located for him. In the case of a company like the Yukon Gold, the ground will have been purchased and the leasing of it means that it is not suitable for large-scale operations on company account.

The photograph of hydraulic mining on this page illustrates operations on the big alluvial deposit known as the White Channel, thus named on account of the preponderance of white quartz pebbles in the gravel. This is a mass of Pliocene drift, as much as 200 ft. thick, but much thicker before it was eroded. From this erosion the creeks of the Klondyke were enriched, more particularly Bonanza and Eldorado, famous during the great rush 17 years ago. Indeed, nearly all the gold of the present low-level valleys is of secondary origin and derived from the re-distribution of the older gravels. This applies also to the flats now being dredged so successfully. These flats are frozen to bedrock except where the live water of the present creeks passes, so that artificial thawing has been necessary. The cost of the thawing has been decreased gradually to one-half what it was, say, seven years ago, but it is still a heavy tax. To decrease this item, it is customary now to strip the moss and frozen mould covering the gravel, so as to expose it to the natural thaw under the sun during summer. In this way the gravel becomes loosened as much as 12 to 16 feet in a single season, as against the maximum penetration of the winter frost to 6 or 7 feet.

HYDRAULICKING THE WHITE CHANNEL DEPOSIT NEAR DAWSON.

Platinum in Southern Nevada

By ADOLPH KNOPF

*Introductory. The discovery of platinum-bearing gold ore at the Boss mine was announced in October 1914. Early in that month an examination of the deposit was made by me, the results of which are here given.

The Boss mine is situated in the Yellow Pine mining district, Clark county, near the extreme southern part of Nevada. The main settlement of the district is Good Springs, distant 8 miles from Jean, a station on the San Pedro, Los Angeles & Salt Lake railroad. Good Springs lies on the east side of a desert range known as Spring Mountain, but the mine is situated on the west slope, 12 miles from Good Springs, by a road that crosses the range through a low pass.

The deposit on the Boss claim was discovered some 30 years ago, having been located for copper, the presence of which is plainly indicated by chrysocolla and other oxidized copper minerals. In the nineties the property was bonded and a leaching plant was built at Good Springs to treat the oxidized copper ore, but, the process proving a failure, the property reverted to its original owners. Not until recently has the gold and platinum content of the ore been recognized. The owners, Messrs. Yount and White, discovered the high gold content by sampling and assaying, and the Boss Gold Mining Co. was organized in March 1914.

The failure to recognize previously the auriferous character of the ore needs explanation. It seems to have been due in part to the fact that, although the ore can be shown by assays or chemical means to carry considerable gold, the presence of the gold, as I have verified personally, is not evident on panning. Moreover, some extraordinarily rich material (the plumbojarosite, assaying as high as $6000 per ton in gold) yields when panned a black residue that might easily be thrown away as worthless black sand. This unpromising black residue when strongly scoured by rubbing it in the pan with a piece of iron, rolls out into yellow flakes and quills, and its identity as gold becomes manifest. The discovery of the platinum content of the ore is due to the acumen of H. K. Riddall, chemist for the Yellow Pine Mining Co. In running assays of the Boss ore he noticed that the gold buttons, instead of being smooth, had rough cauliflower-like surfaces. He suspected that the buttons might contain platinum, and this suspicion was strengthened by the fact that solutions obtained on parting, instead of being colorless, as is the rule when the gold is alloyed with silver only, showed yellow and brown tints, indicating the presence of platinum and palladium. By systematic tests these metals were then proved to be present. This result was soon verified by a number of other assayers, although one supposedly reliable assaying firm in Los Angeles reported that the ore contained no platinum. Two samples sent to the Geological Survey by Mr. Hale were submitted for assay to Ledoux & Co., of New York, who reported on September 9, 1914, as follows:

	1.	2.
	Oz.	Oz.
Platinum	7.38	99.08
Gold	11.55	111.00
Palladium	....	16.00

Note. Concentration by panning shows that the metals are in the free state, being apparently alloys of gold and platinum metals. Owing to uneven distribution, assaying is very difficult and the above results can only be considered as approximately correct. Assay for palladium was omitted on No. 1, but the sample contains 1 or 2 oz. of this metal. A little iridium is present in No. 2.

Prior to the discovery of the platiniferous character of the ore some small shipments of high-grade copper ore and of high-grade gold ore had been sent to the smelter at Salt Lake City, but after the platinum content was recognized, production was suspended, pending arrangement for the advantageous disposal of the platinum and allied metals.

In October negotiations were under way for the treatment of certain lots of high-grade ore by the Pacific Platinum Works, of Los Angeles, whereby this firm agreed to pay $46 per ounce for the combined platinum and palladium content, after deducting a treatment charge of $300 per ton.

Late in the year the mine was sold by the Boss Gold Mining Co. to W. C. Price and associates for $150,000, according to O. J. Fisk, former manager of the company.

The great interest that attaches to so unusual and remarkable an occurrence of platinum and palladium in a gold-bearing lode hardly needs comment. The Boss vein is one of the few primary deposits in which metals of the platinum group occur in more than traces and, with one possible exception (the New Rambler mine in Wyoming), is the only primary deposit of economic importance in which these metals are the constituents of predominant value.

General Geology. The prevailing rocks of the district are stratified dolomites of middle Carboniferous age. They are considerably, though not acutely, folded and are broken by faults. This formation is economically the most important assemblage of rocks in the district, as all of the ore deposits occur in it or in the dikes cutting it.

Limestones of Pennsylvanian age and red sandstones and shales of probable Mesozoic age are also present in the district, but they are of no special concern here, as they lie at a considerable distance from the area in which the Boss mine is situated.

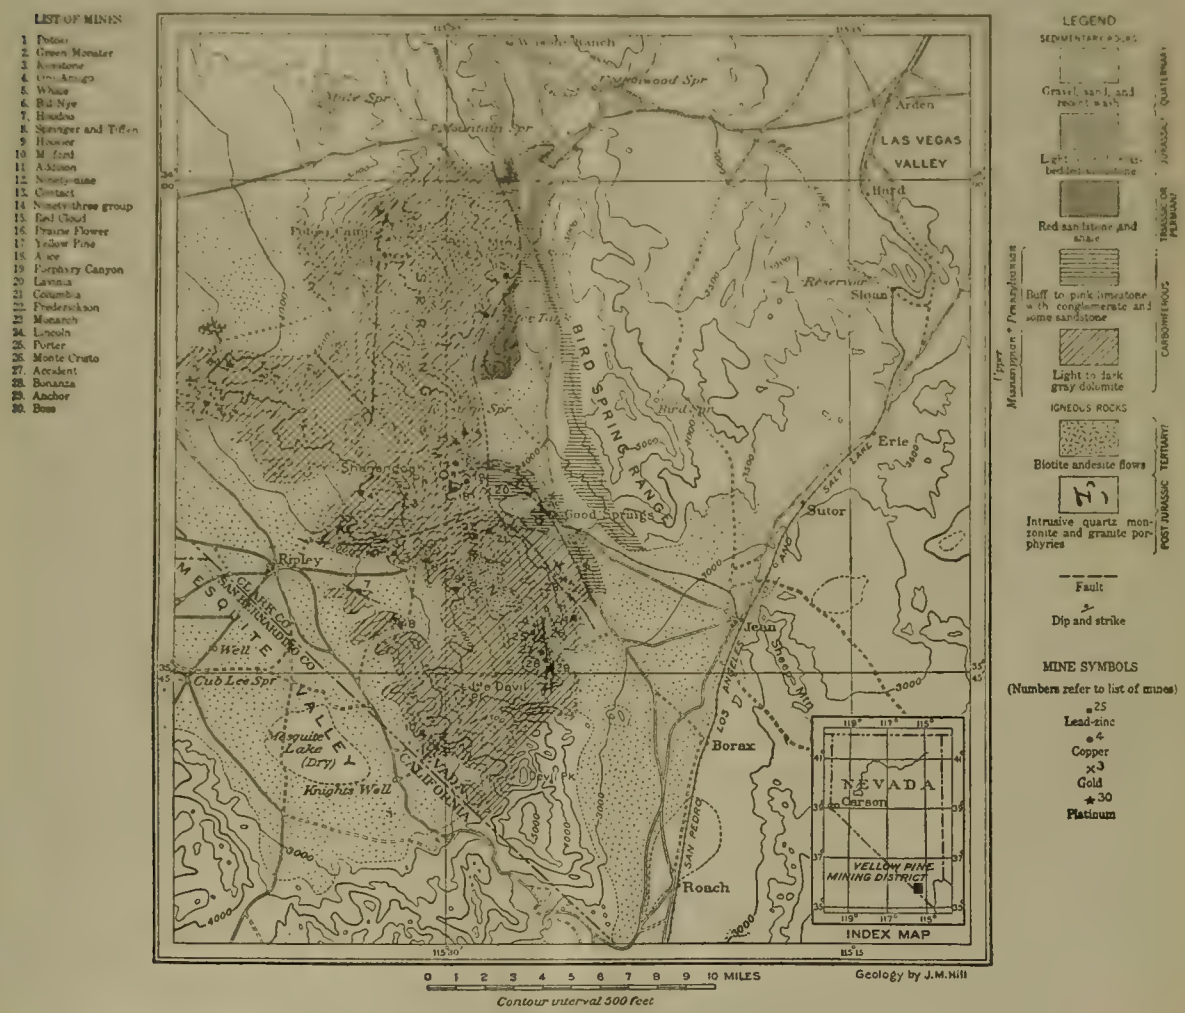
*Abstract from Bulletin 620-A, U. S. Geological Survey, entitled 'A Gold-Platinum-Palladium Lode in Southern Nevada.'

Intrusive igneous rocks are not common in this district, in fact, the areas occupied by them are so small as to be barely perceptible on the geologic map. They consist of stills and short dikes of quartz monzonite porphyry and granite porphyry, as a rule considerably altered.

The principal metalliferous deposits are bodies of lead zinc ores inclosed in dolomite or limestone. The prevailing minerals are smithsonite and cerussite; galena

Some copper deposits have also been developed. They consist predominantly of oxidized copper minerals forming irregular replacements. Tetrahedrite, which has been recognized in the gold ore of the Lavina mine, and chalcocite are the only copper-bearing sulphides found in the district.

Finally, brief mention should be made of the so-called vanadium deposits. On the Bill Nye claim, for example,



SKETCH MAP OF YELLOW PINE MINING DISTRICT, CLARK COUNTY, NEV.

occurs to some extent, but zinc-blende, presumably the parent of the oxidized zinc ores, is present in only one mine.

Gold deposits were formerly of some importance in this district, the Keystone mine, the most productive, being credited with an output of $1,000,000. At this mine the gold is disseminated through quartz-monzonite porphyry, which has been highly altered by the development of sericite and siderite. In general, the deposits are closely associated with the porphyry dikes and may stand in genetic relation to them. Certainly the chemical alteration produced in the porphyry dikes indicates that the ore-forming solutions were ascending thermal waters.

a dolomite breccia cemented by a copper-bearing lead vanadate, probably cupro-descloizite, forms a tabular deposit 18 to 24 inches thick, which has been exposed by an incline to a depth of 12 feet.

The Yellow Pine district, in which the Boss mine is situated, is the most productive zinc and lead district in Nevada. In 1913 it yielded 29,060 tons of ore, containing $1268 in gold, 192,339 oz. silver, 283,592 lb. copper, 6,204,065 lb. lead, and 14,369,709 lb. zinc, valued in all at $1,239,081.

The rock at the Boss mine consists of dolomite in beds ranging from a few inches to several feet thick. The beds comprise a dark-gray or black variety, fetid with

hydrogen sulphide on fresh fracture, and a more prevalent pale-buff variety. They not uncommonly carry crinoid fragments and are of late Mississippian or early Pennsylvanian age—that is, middle Carboniferous.

The rocks strike east and dip gently north. The structure is that of a broad anticlinal arch, whose crown has been broken by faults. In the immediate vicinity of the mine the rocks are practically horizontal.

A small mass of granite-porphyry or dike of no linear persistence occurs 600 ft. north of the mine. This rock is characterized by numerous large corroded phenocrysts of quartz and kaolinized feldspars embedded in a fine-grained groundmass. It accordingly resembles the small masses of intrusive granite-porphyry and quartz-monzonite porphyry scattered throughout the district. The porphyry is highly altered and has been considerably prospected for gold, but has proved of too low grade to be profitable, carrying at best only a few dollars in gold.

The orebodies so far developed are characterized by oxidized copper and gold-platinum-palladium. The copper ores consist largely of chrysocolla and colloidal complexes of chrysocolla and limonite; these ores are reported to carry only minor amounts of the precious metals. The gold-platinum-palladium ore consists of a fine-grained silicious matrix containing a bismuth-bearing variety of plumbojarosite (a hydrous sulphate of iron and lead). There is no fixed ratio between the content of gold and the platinum metals, nor between the content of platinum and palladium. This variability seems to be a result of the prevailing oxidized condition of the ore. The palladium is probably in excess of the platinum.

The copper ore-shoots and the precious-metal ore-shoots can be mined separately, it is said. This segregation of the metals that makes this feasible will assuredly be found less complete as depth is attained.

The orebodies of the Boss mine occupy a nearly vertical zone of fracturing in the horizontal strata of dolomite. At the surface this zone is 30 ft. wide, but the precious-metal shoots are confined to the 12 ft. resting on the foot-wall. The length of the mineralized zone exposed on the surface is about 100 ft., but the orebodies do not extend continuously over this distance. At the portal of the upper adit the foot-wall strikes N 5° E and the hanging wall strikes N 25° E. The principal ore-shoot forms an irregular pipe pitching at a low angle northeast.

The dolomite within the zone of fracturing has recrystallized to a coarse white spar, and this dolomite spar makes up the rock inclosing the ore-shoots.

PLUMBOJAROSITE. A particularly rich shoot of ore has been developed by a winze sunk from a point near the end of the upper adit. In this shoot are small masses of what are locally known as greenish talc. Some of these were mined separately and two shipments aggregating about 1 ton were sent to the smelter at Murray, Utah. On a control sample of this ore, Ledoux & Co. reports as follows: Gold, 111 oz.; platinum, 99.08 oz.; palladium, 1% oz. per ton; iridium, trace.

The "greenish talc," determined chemically and microscopically, proves to be a bismuth-bearing variety of the rare mineral plumbojarosite. It is a greenish-yellow mineral of smooth unctuous feel, which under the highest power of the microscope is seen to consist of perfect hexagonal tablets averaging 0.01 millimetre in diameter. It carries considerable mechanically admixed gold and platinum metals. An analysis of the purest obtainable material was made in the laboratory of the United States Geological Survey by R. C. Wells, with the following results:

Fe_2O_3	31.80	CO_2	0.43
Al_2O_3	0.14	As_2O_5	0.09
SO_3	24.08	P_2O_5	trace
PbO	16.75	SiO_2	6.90
H_2O-	0.02	TiO_2	0.37
H_2O+	8.55	Au	0.79
CuO	1.97	Pt	0.05
Bi_2O_3	6.34	Pd	0.22
CaO	0.06	Ir	trace
MgO	0.14	Ag	trace
K_2O	0.22		
Na_2O	0.52		99.88

Reduced to ounces per ton, the analysis shows gold to be present to the extent of 234, platinum 15, and palladium 64 oz. Assays of similar material are reported to show as high as 575 oz. gold, 230 oz. platinum, and 30 oz. palladium. The silica and titania shown by the analysis represent an admixture of quartz and octahedrite.

The gold and platinum metals can be partly separated from the plumbojarosite by panning, but long before a clean separation can be effected fine gold and especially platinum pass into the tailing, in spite of the utmost precaution. The gold is extraordinarily rough and spongy; delicate platy forms are common, and some is intergrown with quartz and plumbojarosite or is molded around minute quartz crystals. It is more or less blackish, and aggregates of the finer particles look like so much black sand. Treatment with hydrochloric acid and annealing, however, bring out the normal yellow color of gold.

The pockets of plumbojarosite occur in a porous, fine-grained silicious gangue, which is a replacement of the dolomite. The pores and cavities evidently resulted from the leaching of sulphides; they are now partly filled with malachite in small botryoidal groups, or more commonly with powdery plumbojarosite.

The only sulphide-bearing ore exposed in the mine at the time of visit was in the sub-level below the upper adit. Here, in particularly tight ground, about 3 ft. of copper ore rich in chalcocite had been opened. An average sample of this ore, as reported by the management, showed copper 15.1% and platinum metals 0.40 oz., gold 0.13 oz., and silver 1.2 oz. per ton.

The chalcocite, which is of the steely kind and shows conchoidal fracture, occurs as small blebs and finely disseminated particles embedded in a close-grained silicious gangue. It is partly altered to brochantite, the basic sulphate of copper, which forms small glassy emerald-green prisms implanted on the sulphide from which it was derived. Examination of this ore under the micro-

scope shows that it is an aggregate of quartz, chalcocite, and brochantite, with octahedrite present as a rare accessory mineral; the brochantite occurs in partial replacement of the quartz and is somewhat more abundant than would be estimated from inspection by the unaided eye. An oxidized bismuth compound is associated with some of the chalcocite.

GENESIS OF THE ORE. The Boss deposit represents in the main an irregular silicious replacement of dolomite along a series of vertical fractures. On account of the prevalent oxidation and the inconsiderable depth to which the workings have penetrated, primary sulphides have not yet been reached. The chalcocite, the only sulphide so far found, most probably originated as a precipitate from downward-moving solutions whose copper was derived from primary sulphides formerly exposed to oxidation near the surface.

The deposit yields as yet no especially strong evidence concerning the genetic conditions that prevailed at the time it originated. Some clue is perhaps afforded by the presence of the titanium oxide minerals, octahedrite, and rutile. Both of these are rather uncommon in metalliferous deposits. Of the two, rutile is the more common. It is, for example, somewhat abundant in certain of the auriferous deposits of the Juneau gold belt, which are veins that originated at high temperature; in fact, according to W. H. Emmons,* rutile is restricted to high-temperature veins. Octahedrite occurs in the tourmaline-bearing copper veins of Las Condes, Chile;† in tin veins of Saxony associated with apatite, fluorite, and chlorite; and in fissure-fillings in the Alps, but these veins are not notably metalliferous. The Alpine veins are thought to have formed at temperatures between 250 and 400°. In view of the affiliation generally shown by the octahedrite and rutile with deposits of high-temperature origin, the suggestion is advanced that the primary ore of the Boss deposit was formed under conditions of moderately high temperature.

The facts at hand cannot of themselves be held to prove that the ore deposition was genetically connected with the intrusion of any particular dike or igneous mass now visible at the surface. It is probable, nevertheless, that the mineralization followed as a sequel to the intrusion of the magma from which the granite-porphyry dikes were derived, for these are the only intrusives that penetrate the rocks of the district.

The deposit, as already described, is highly oxidized and contains abundant oxidized copper compounds and plumbojarosite. These minerals indicate that the primary sulphides will be found to carry copper, iron, lead, bismuth, and precious metals. The extraordinary richness in gold, platinum, and palladium of ore containing notable quantities of plumbojarosite raises an important problem. It is not impossible that the plumbojarosite may have originated essentially in place by simple oxidation of sulphides that were extremely rich in precious metals. A partial analogy for this supposition is furnished by the development of the brochantite in the chalcocite-bearing ore; the brochantite appears to have formed in place from the chalcocite without any important migration of copper. For the origin of the plumbojarosite, however, the following explanation appears to fit the known facts more closely. B. S. Butler,‡ who has recently shown that in the oxidized ores of Utah plumbojarosite is rather common, although heretofore unrecognized, believes that in the occurrences studied by him the plumbojarosite was produced by the action of ferric solutions on galena; the lead has remained essentially in place, but the iron may have come from some distance. It is therefore suggested that in the Boss orebody descending solutions rich in ferric sulphate attacked primary galena, forming the plumbojarosite, and that this reaction caused the concomitant precipitation of the gold, platinum, and palladium. According to this explanation, an efficient solvent for the precious metals was active and in this connection the fact established by R. C. Wells, during the chemical investigation of the plumbojarosite, that the precious metals are rather soluble in hydrochloric acid in the presence of plumbojarosite is highly suggestive.

On the whole, then, it is likely, in view of the probable mode of origin of the plumbojarosite and of the evidence of leaching indicated by the porous nature of the silicious ore, that a certain amount of re-distribution of gold, platinum, and palladium has taken place by the action of descending surface solutions. It would follow, then, that in depth, below the zone of oxidation, the pockets of extremely high-grade ore, such as are now being extracted, will be found to give way to ore of moderate grade.

Milling Costs at Goldfield Consolidated

In 1914 the 100-stamp mill and cyanide plant treated 332,750 tons of ore at the following cost:

Department.	Per ton.	Department.	Per ton.
Crushing and conveying.	$0.046	Surface and plant	$0.005
Stamping	0.124	Steam heating	0.001
Chilean mills	0.103	Store and office	0.013
Elevating and classifying	0.020	Stable	0.002
Tube-mills	0.242	Watchmen	0.022
Concentration	0.052	Superintendence	0.045
Neutralizing	0.061	Lighting	0.018
Settling	0.069	General expense	0.007
Dissolution	0.461	Mill tools	0.003
Filtering	0.062	Electrical department	0.018
Residue	0.002	Pumping battery water	0.025
Assaying	0.019	Experimental	0.002
Precipitation	0.062	Clean-up	0.024
Refining	0.046	Total	$1.606
Water	0.052		

In the total charges, labor absorbed 21.86%, supplies 56.60%, and power 21.54%, and in the combined cost of milling and concentrate treatment these were reduced to 18.44%, 47.77%, and 18.18% respectively.

CONCENTRATES

Readers of the MINING AND SCIENTIFIC PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

EVERY EXPLOSIVE when exploded exerts pressure in all directions.

MOST EXPLOSIVES suitable for use in such work as quarrying are unsuitable for use in deep mines or in close workings.

PLATINUM found its first use as a material for resisting chemical action. It is now used in jewelry, particularly for setting diamonds; also in electrical apparatus.

GRANULATED NITRO-GLYCERIN POWDER such as is generally sold in the United States contains about 5% nitroglycerin, 35% combustible matter, and 60% sodium nitrate.

A RELIABLE THERMOMETER should be placed in all thawing-houses for explosives. It should be visible from the outside. The maximum temperature is not to exceed 80° Fahrenheit.

CHROMITE at Selukwe, Rhodesia, is found in schist in lenticles that are original crystallizations of the igneous magmas from which the schist has been derived by metamorphism.

CADMIUM is a deleterious impurity in zinc, as employed in the making of brass, if present in excess of 0.5%. Up to 0.25% the presence of cadmium in spelter exerts no unfavorable effect.

POTASH SALTS occurring in the mud of Columbus marsh, Nevada, have been absorbed from solution and are held in loosely combined form, according to the investigations of W. B. Hicks.

ELECTROLYTIC BATHS are not of service in cases of lead poisoning, according to the views of a recent investigator, as the lead accumulated in the tissues is a part of organic compounds not easily ionized.

CHROMITE BRICK can be used to advantage in reverberatory furnaces for smelting antimony, arsenic, bismuth, and tin, because the slags produced in the reduction of these metals are extremely corrosive and the oxides act as acids in attacking a basic lining, so that a neutral material is desirable.

PYRITE CONCRETIONS in South African sandstones are derived from pyrite nodules formed by replacement of the sandstone. Atmospheric and surface-water action on these produce the concretions, according to R. B. Young.

THE PANAMA CANAL is now operating at a profit. In March the tolls amounted to $560,785. Operation and maintenance cost $423,275. The surplus was $137,510. Since July 1, 1914, the total revenue is $2,895,300; charges, $3,018,889; deficit, $123,588.

CONCRETIONS containing large amounts of iron, manganese, and alumina found in Germany lying about a foot below the surface of soil overlying diluvial sand are thought to have originated from the precipitation of iron and manganese coming in solution from below.

MINE TIMBER should be properly cared for on the surface while waiting to be used underground. Important factors affecting the amount of deterioration are as follows: position of the yard, method of piling the lumber, climate and season of the year, and dimension of the stock.

PLATINUM production of Russia decreased in 1914 from 173,642 to 156,775 oz. The market for the metal was principally France and Germany. In July 1915 there is to be an export duty of about 30% placed on raw material. This will result in refineries being started in Russia.

LOCAL TERMS in the Wisconsin zinc district are as follows: 'dirt,' ore and waste as broken in the mines; 'sulphur,' iron sulphide; 'jack,' zinc sulphide; 'lead,' galena; 'tiff,' calcite; and 'velvet,' profit, referring to the galena when not too intimately mixed with blende to allow easy separation.

PICRIC ACID is used in the manufacture of ammunition. It is made by mixing carbolic acid with strong sulphuric

acid. The sulphonate is diluted with water. The liquor is then poured slowly into nitric acid. This is allowed to cool. The crude picric acid crystallizes out, and is purified by re-crystallization. All traces of nitric and sulphuric acids are washed out with water. The crystals are then dried, graded, and packed. When heated or struck, this salt explodes violently. Organic substances treated with nitric acid yield the acid.

Labor employed at the Modder B. mine, on the Rand, in 1914 averaged 319 whites and 2023 colored persons. This force mined 470,489 tons of gold ore, of which 440,000 tons was treated. The average stoping width was 59 in. Last year the Bunker Hill & Sullivan company, Idaho, mined and treated 440,819 tons of lead-silver ore. The lodes are wide, and generally worked by adits. A total of 620 men was employed in December. Operating expenditures were $4.74 and $2.64 respectively at the two mines quoted.

Chemicals permitted to be used as coloring matter in food in Canada are as follows: Caramel, cochineal, saffron, chlorophyll and innocuous vegetable color extractives, certain coal-tar dyes not containing arsenic in excess of 10 parts As_2O_3 per million, calculated on the actual weight of coloring matter, and not containing heavy metals (except iron), when used in quantities not exceeding 2 grains per pound (1 part in 3500). The use of copper salts in the greening of peas is permitted, provided the amount of copper (expressed as metallic copper) in the peas does not exceed 80 parts (by weight) per million in the drained peas, or 10 parts per million in the liquid. These substances are considered to fall within the definition of harmless coloring materials.

The zinc-mining district of southwest Wisconsin is situated in the centre of a rich farming region. The fee-owners of the land are usually farmers. The prevalent custom is for an operating company to lease ore-bearing land from the fee-owner. A royalty, usually 10% of the gross receipts, is paid as rent or as the fee-owner's share of the earnings. Unless otherwise stated in the lease, the owner pays all real property taxes on his fee. If the land covers an ore-deposit, he must pay a real property tax on an increased assessment, due to the increased value of the land, as well as an income tax on his royalty from the mine. Sometimes a mining company buys the area it intends to mine. In this case the company pays all taxes on the property and on income from the property. The surface is usually leased to others. Again, a company, after buying the land outright, sells the surface. In this instance the mineral rights are assessed separately on the same basis as real estate, that is, to the fee-owners of the mineral rights.

Oil wells that have passed the flowing stage and are being pumped, may still continue to give off much gas at the casing-head. The quantity may vary from little or nothing at some wells to 500,000 cu. ft. or more at others. When enough of the gas is available it is used for pumping on the lease, the excess being wasted. A steam pumping engine of 50 hp. requires about 25,000 cu. ft. of gas for 10 hours' operation. From 12 to 15 cu. ft. of natural gas is needed per horse-power-hour for gas engines that are used on leases for pumping oil wells. If there is not enough of the gas available for working pumps, it is all allowed to go to waste, or perhaps some is used for heating and lighting a few scattered houses on the lease. The efficient utilization of the casing-head gas ordinarily is a difficult problem. The many miles of pipe that would have to be laid to transport it from a field would usually be an unjustifiable expense. However, some towns, among which may be mentioned Warren, Pennsylvania, and Sistersville, West Virginia, are lighted and heated largely with casing-head gas. In general, however, the oil-man considers casing-head gas as waste gas and its escape necessary in oil-well operations to permit the maximum flow of oil into the well from the surrounding strata.

Sublimed white lead is an amorphous white pigment possessing excellent covering and hiding power, is very uniform, and fine in grain. It is a direct furnace product, obtained by the sublimation of galena. It is largely used by paint manufacturers. It is a stable and valuable paint pigment. Samples of the product are to be seen at the Missouri mineral booth at the Exposition. The Dutch process of making white lead depends on the action of carbonic acid gas from decomposed tan bark and manure, in the presence of vinegar, on pig lead. The acid salt that is then formed is slowly converted into a hydrated carbonate. This process is in operation at the exhibit of W. P. Fuller & Co. at the Exposition. The plant is as follows: Selby pig-lead is melted in a 2500-lb. capacity furnace. The temperature is 800°F. The molten metal is cast into lead buckles on a perforated chain casting-machine. The buckles are ⅛ in. thick, weighing 4 oz. In a large plant they weigh 16 oz., being 6 in. diameter, and the usual thickness. An elevator carries the buckles to a pile. They are then laid in earthenware corroding-pots. The bottom portion of the inside is glazed; above this it is porous. Twenty ounces of diluted vinegar, equal to 3% acetic acid, is put in the pots. The charges are arranged in layers in damp tan bark. In about 10 days this ferments, a temperature of 165 to 170° being attained. The heat vaporizes the vinegar, acetic acid attacks the lead in the pots, forming lead acetate; carbon dioxide from the bark then attacks the acetate, changes it to basic lead carbonate, and releases acetic acid, which again reacts on the metallic lead. Time taken for complete corrosion is from 90 to 100 days. The dry carbonate is taken from the pots, powdered, ground with water, washed and floated, passed through 200-mesh silk, thickened in a series of settlers, pumped to a storage-tank, and weighed in charges. An agitator next mixes the thick lead with the required amount of oil. This form of lead mixes well with oil. The remaining water, which floats above the mixture, is run off. The white lead is finally ground twice by stones, cooled, and filled into steel or wood kegs of various sizes.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

MANILA, PHILIPPINE ISLANDS

MINING ASSOCIATION.—MINE TAXATION.—GOLD OUTPUT.—BENGUET CON. MILL AND MINE.—DREDGING.

The operators of fourteen of the leading gold-mining properties in the Philippines have recently organized themselves into an association to be known as the Philippine Mining Association. The purposes of this organization are to bring accurate information concerning Philippine mining before the public both locally and abroad. To this end the society will publish a bulletin for free distribution, to be issued from time to time, and will attempt to furnish authoritative information concerning Philippine mines and mining conditions. It is hoped that one result of this publicity will be an increased interest in local mining on the part of American investors. It has not been possible up to the present to interest any large American capital in Philippine mining ventures. The various concerns now operating were financed either locally, on the China coast, or in Australia and New Zealand. Judge Frank

VALLEY OF AUTAMOK RIVER, BENGUET MOUNTAIN PROVINCE. TOP CENTRE SHOWS SITE OF BENGUET CONSOLIDATED MILL.

B. Ingersoll, general manager of the Gumaos Placer Co., managing director of the Malaguit Dredging Co., and an official in several other organizations, is president of the Association.

Another line of endeavor on the part of the organization will be an attempt to counteract the tendency toward increased taxation of mines, which was manifested in the last legislature, by educating the public to an accurate knowledge of Philippine mines and mining, so that they may be in a position better to judge as to the fairness of increased taxation. A tax of 1½% was imposed on the gross output of gold mines after the first of last January. The original law provided for a tax of 5% of the gross output of precious and semi-precious metals, but after a series of public hearings by the committee to which the bill was referred, the tax was diminished to 1½% and imposed on the output of gold mines only. Since the bullion from most of the mines carries a small proportion of silver, the tax applies to silver as well as gold in practice. Mining men generally opposed the taxation on the ground that the industry was too young to survive without serious injury. As it works out in the case of one of the larger companies, the increased taxes amount to about 2½% of the total capitalization.

In spite of adverse legislation, however, the last few months have seen much advance in the progress of gold mining. The Philippine production of gold for the year 1914, according to the figures prepared by the Division of Mines, Bureau of Science, was ₱2,349,267, an increase of nearly 36% over the production for 1913. The figures given out by the Director of the United States Mint for the gold production of the Philippines in 1914 are ₱2,120,000, a sum that probably does not include bullion in transit nor bullion sold in Europe and Japan.

More than 50% of the Philippine production came from lode mining at Araroy, Masbate, where four mills with a combined capacity of about 300 tons daily are in operation. The seven dredges in the Paracale-Mambulao placer region yielded more than ₱1,000,000 in 1914. The larger part of the remainder of the output came from the Mountain province, where one 10-stamp mill, two 3-stamp mills, and one 5-ft. Huntington mill were operating during a part of the year. Filipinos, working on the Palidan slide near Mancayan, recovered more than ₱40,000 worth of gold by panning during the past year.

The Benguet region in Mountain province will undoubtedly become an important contributor. The 10-stamp mill on the Headwaters property is being profitably operated under lease. The Acupan Mining Co. is assembling a 3-stamp mill on a claim, which is known to be good, on Batuan creek, and the new 10-stamp mill of the Benguet Consolidated Mining Co. is rapidly nearing completion. Twice previously floods have carried away the mill on the Benguet Consolidated property, so that the new mill is the third to have been erected there. C. M. Eye, general manager for the Benguet Consolidated Co., who has had entire charge of the design and erection of the new plant has supplied the following notes on the present condition of the property:

The new mill will be of the all-sliming, cyaniding type, and its equipment will include: one 8 by 12 Hercules Blake crusher; ten Hendy stamps of 1050 lb. with high narrow-discharge mortars set on wooden blocks; one Dorr duplex classifier in closed circuit and on the same level with a Denver Engineering Works, 6 by 10 ft. tube-mill; elevator from classifier to a primary Dorr thickener in a 25 by 12-ft. vat; three Dorr agitators in series in 14 by 12 ft. vats for continuous work; four secondary thickeners in series in 25 by 12 ft. vats, arranged to work on the continuous discharge counter-current system; one clarifying vat with canvas leaf-filters and wet-vacuum pump; three double-line, 7 compartment zinc-boxes, made by the Atlantic, Gulf & Pacific Co., Manila; two Gould triplex pumps for solution transfer, each with a capacity of 75 gal. per min.; a battery of Gould diaphragm pumps between thickeners for pulp transfer; an automatic tailing-sampler following the line of vats; and a complete clean-up equipment including a Case oil-fired tilting furnace. The solution-flow is recorded automatically in tons per 24 hours by means of a recording-gauge on a small vat, from which the solution escapes through a calibrated standard orifice. All tankage is of corrugated steel, the choice of material being governed partly by the saving made possible in freight charges, which are excessive in this region.

Power will be distributed by General Electric motors; the stamps are on a 25-hp. back-geared motor and the tube-mill is operated through a friction-clutch by an ordinary 50 hp. motor. The total motor horse-power is 105, while the maximum load with the crusher in operation is estimated at 100 hp. Hydro-

electric power is to be generated by a Pelton-Doble wheel direct connected to a 120-kw. generator situated down-stream from the mill. The pipe-line is 6000 ft. long and yields a head of 300 ft. gross, 260 ft. net, with a flow of 5 second-feet. The diversion-dam is made of logs on a concrete footing and is 18 ft. high by 45 ft. long. Electric current will be transmitted at 2380 volts over a transmission line 2400 ft. long to the mill, where the voltage will be stepped down to 220.

A new adit is being driven from the lowest practicable elevation to drain the old workings. This adit will be about 500 ft. long when it reaches the vein. A new adit will also be driven from the present mill-site to the upper levels of the mine to serve for a haulage-way. An old cross-cut is being extended on the line of this adit and during the advance the cross-cut recently passed through 41½ ft. of ore assaying 180 pesos per metric ton. Concentrate from this ore assayed more than 4000 pesos per ton. The vein in the old mine is being developed to the eastward by a drift along the hanging wall with cross-cuts to the foot-wall at 50-ft. intervals; the first of these cross-cuts revealed 6½ ft. of ore assaying 160 pesos per ton, while the second cross-cut, just completed, encountered 9½ ft. of ore assaying 70 pesos. On the level of the old drainage-adit, which is about 80 ft. below the new mill-adit, there is more than 1000 ft. of old workings which was driven through good ore. This part of the mine is now flooded but will be unwatered by the new adit.

The Cansuran Placer Co., which recently began hydraulicking operation on Cansuran creek about 12 kilometres south of Surigao, the capital of Surigao Province in Mindanao, will also be a producer of gold this year. The company is hydraulicking several adjacent areas of coarse gravel aggregating 325 acres. The ground was taken up on the recommendation of R. Y. Hanlon, who tested the gravel by digging a series of 181 holes and obtained an average of 44 centavos per cubic yard over the territory to be worked. The average depth to bedrock is 4 yards. The gravel is coarse but the individual boulders are embedded in clay. Water is obtained from the head of Tuganan river and conveyed to the claims through ditch, flume, and pipe-line with a total length of over a mile. The head varies from 100 to 300 ft. over different parts of the ground to be worked. Two 6-in. monitors and one 7-in. monitor are in place and an area of about 5 acres will have been cleaned-up within a short time. The work has been hampered by a shortage of water during the present general drouth.

The Australian dredges, at Paracale, which now number four, have had a normal run during the past year and yielded the usual dividends. The Malaguit dredge has lost some time because of the necessity of replacing some of the machinery, but has made a generally satisfactory record. The Gumaos dredge has finished its second year of operation with a total production of ₱912,205 (two years and three months time). The sum of ₱535,000, or 107% of the capitalization, has been distributed in dividends during this period. The average value of the Gumaos ground for monthly dredge-runs has varied from 5 centavos to ₱1.28 per yard. At places the dredge has dug to a depth of 52 ft., while elsewhere bedrock was encountered at 20 ft. or even less. These data afford an idea of the irregularity of the dredging ground in this district. The average value per cubic yard for the period of operation has been 49 centavos. The average depth to bedrock has been about 35 ft. and the average cost of dredging, about 18 centavos per yard.

According to Press Bulletin 40 of the Bureau of Science, Manila, the division of mines has received a number of inquiries concerning the discovery of gold near Iligan, Mindanao, which was reported in the local press several months ago. The discoverer of the new field is Allen Smith, Jr., of the Philippine Scouts. He has released to the public certain information supplied by him to the Bureau of Science. The claims located are 12 miles east-northeast of Iligan. The deposit is a conglomerate. Twenty assays have been made on the material, 17 of which return from ₱6 to ₱30 per ton. If the samples were properly taken, these results are interesting. There is plenty of conglomerate in the Islands, but it is not generally of any commercial value. An engineer made an examination of the area in May.

CRIPPLE CREEK, COLORADO

STRATTON'S AND PORTLAND LEASING SYSTEMS DISCUSSED.

The excitement of the week has been the reported sale of Stratton's Independence to the Portland Gold Mining Co., the adjoining property to the north. We may now conclude that the era of consolidation has arrived. In many ways it is the logical step; in others it is not going to be such a good thing for the district. Such consolidations result in greater economy generally, but it is equally true that fewer men will be employed, and that less money will be in circulation here. It will hurt leasing somewhat, as both of these mines have done considerable leasing in the past under different systems. The Independence has used a flat royalty with a profit-sharing system attached, which has been very satisfactory to both lessee and company. Many of the men now leasing have been there since the leasing system was inaugurated. The Portland company has been experimenting with the 'split-check system,' which has hardly had a fair trial yet. The fault with this system is that where the company supplies all the material and the lessee supplies all the labor only, the former wants to say where the dead-work is to be done, and how much it is willing to stand. In the other system the lessee uses his own judgment entirely, and works his block any way that he sees fit, provided only that it is done in a workmanlike manner. The Independence charged a flat royalty of 30%, and supplied air and machines, and until recently, hoisting, free. The time of each lessee and his crew was kept, and $5 per shift was allowed for each shift worked. Thus, when a settlement was made, the 30% royalty was first deducted. Then allowance was made for the number of shifts worked. If the amount then due the lessee was $300 to $1000 he was charged a further 20% of the sum, whatever it was, between $300 and $1000, or 30% on sums between $1000 and $2000. The drawback to this system was that the company had to do all the development. The lessee would work when there was ore in sight and not otherwise. As a practical comparison of the two systems, it may be said that the Independence lessee either made over 50% of the net returns, or there was relatively no net returns at all. The fact that the company made its dividends right along is pretty good evidence that the lessees made good profits. How long could a company last on the split-check system when the net returns failed to pay expenses? It is not yet known what the new policy will be on the Independence, but most of the present lessees have made application to the new owners to retain their leases. How a reduction in the number of lessees would affect the camp is easily seen, and it is to be hoped that no leases will be cancelled, but rather, that more will be granted.

GOLDFIELD, NEVADA

JUMBO EXTENSION.—BOOTH SUIT SETTLED.—VELVET CLAIM.—MERGER RESUMES WORK.

A deed has been filed for record in the office of the recorder of Esmeralda county, transferring to the Jumbo Extension Mining Co., from the Reorganized Booth Mining Co., all title to ore and veins found in the Velvet, Polverde, and Dick Bland Fraction lode claims, the property of the Jumbo Extension company, within the extended end-line planes of the Booth claim. This is the first deed ever filed in this county in settlement of an apex-suit. The document had attached revenue stamps valued at $315. It is expressly stipulated in the deed that the Booth company does not, by this deed, sell or transfer

any extralateral rights other than those within the territory specified, but reserves its rights in all territory beyond this ground, to the southeast of the Jumbo Extension claims. This, it is said, is the object of transferring apex-rights by deed, instead of in the customary manner of ceding such rights. The terms were discussed editorially in the *Press* of May 29.

Under the terms of a tentative agreement between the two opposing factions of the Merger Mines Co., all litigation is to be terminated; but the minority faction retains the right to bring suit against the Jumbo Extension company for the recovery of the Velvet claim. It is conceded by all who are interested that the only issue on which a suit can be based is the validity of the sale of the Velvet claim by the Merger Mines Co. to the Jumbo Extension. The opinion is held generally by the best authorities that this transaction cannot be questioned. The possibility of any further litigation, involving the Jumbo Extension company, is regarded as remote. There is no likelihood of any serious dispute between the Florence and Atlanta companies, as it is realized that it would require an expenditure of a large sum of money and entail work for at least three years before any apex could be established here, even if it exists. It is probable that these companies will enter into a side-line agreement in the near future.

Work has been resumed by the Merger Mines Co., under the direction of the receiver, Carl Johansen, for whom W. C. Rannells is acting as superintendent. Mr. Rannells had charge of the famous Hayes-Monnette lease at the Mohawk. A. I. D'Arcy continues as general manager for the Merger company, and the work is supervised by him. Drifts have been started, east and west, from the top of the rise from the 1265-ft. level, which cut the shale-latite contact. Interest centres in the east drift, by means of which it is hoped to find the Jumbo Extension ore-channel here.

TORONTO, ONTARIO

Nickel Mining and Smelting.—Steel Balls in Tube-Mills.—Vipond, Crown Chartered, McIntyre, Temiskaming, and Princess Mines.

The great demand for nickel for the manufacture of war munitions has stimulated nickel mining at Sudbury. The Canadian Copper Co. is extracting more ore from the Creighton mine than before. It is making preparations to increase the output considerably. A new inclined 5-compartment shaft is being sunk. A new hoisting and crushing plant will be installed. Many new houses are being erected for accommodation of a large working force. The reverberatory-furnace department, which has been closed since August is again in operation. It will treat the fine ore and dust, about 15,000 tons per month. The ball-mill and Wedge furnace-plant used in connection with the reverberatory has also been started. The construction of a new 25-ft. blast-furnace, larger than any in the district, has been begun.

Recent experiments with steel pebbles in Hollinger tube-mills have proved highly satisfactory. They indicate the possibility of crushing 20 tons per stamp per day. A new electric hoist is being installed at the Hollinger main shaft. It will enable a large tonnage to be raised from the 1500-ft. level.

The annual report of the Vipond company shows a deficit of $33,365 for the year ended March 31. During the last quarter there was a surplus of $26,605.

The Crown Chartered Co. is being liquidated. The property is advertised for sale by tender receivable up to June 8.

At the McIntyre, No. 4 vein is opening well on the 600-ft. level. It has widened to 26 ft., assaying $12 per ton.

The Temiskaming & Hudson Bay is resuming work at its No. 2 property to the south of the Little Nipissing. The Cobalt Lake fault runs through the property. Geological conditions are considered favorable.

The Princess mine has been leased by La Rose Consolidated to Sidney Smith, of Haileybury, on a royalty basis.

According to A. A. Cole's annual report, the amount of ore treated at Cobalt in 1914 was 743,531 tons. This was an increase of 78,686 tons over 1913. Concentrate shipped totaled 12,682 tons containing 3,847,806 oz. silver. Seventeen plants operated during the year. Since 1908 there has been 2,727,12[illegible] tons treated in the district. Further abstracts from this report will be made for the *Press*.

QUEBEC, CANADA

Mineral Output in 1914.—Asbestos, Copper, Mica, and Graphite.—Men Employed.—Control of Properties.—Prospects.

The total mineral production of the province of Quebec in 1914 amounted to $11,325,428. In 1913 it was $13,119,811. However, there has been a fairly steady growth since 1902 and 1903, during which it was less than $3,000,000 each.

The official figure for the province's production of asbestos in 1914 shows a value of $2,900,839, compared with $3,830,504 in 1913. This is due almost entirely to no exports to Germany in the latter half of the year. So hard hit was the asbestos business in the early period of the War, that most of the mines practically discontinued operations. It is gratifying to note, however, that the demand picked up early in 1915, principally due to increased use in the United States, where exceptional efforts are being made to capture the trade of asbestos manufactured products for South America, formerly almost monopolized by Germany. As an index of the amount of asbestos rock which has to be mined to obtain the relatively small percentage of 'fibre,' which is the product sold from the mines, in 1914 there was mined 2,127,395 tons, from which only 120,652 tons of asbestos fibre was obtained and sold, less than 6%. It is evident that, though the fibre brought a price varying from $11 per ton, for the poorest milled grade, to $300 per ton for the long, silky, crude product, with a total average value of about $27 per ton, that the 2,127,395 tons of rock mined, being finally worth only $2,900,839, makes the surprisingly low figure of less than $1.40 per ton of rock mined. This shows that the business must be economically done.

It is interesting to note that copper production of the province is a considerable item. There are two producing mines and several prospects. The most striking success in the copper field of Quebec is the McDonald mine, of the Weldon Mining Co. near Weldon station on the Quebec Central. The copper and sulphur ore of the province produced in 1914 was valued at $801,129 from 117,778 tons, against $812,899 in 1913.

The mica industry, which produced $117,083 in 1913, decreased to $55,636 in 1914. This represents 423,821 lb. of the material, or an average value of about 13c. per pound. Of course the selling price per pound of mica varies through extremely wide limits. It fluctuates with the size of the sheets, quality, toughness, etc. It was to be expected that the War would interfere with Quebec's output, since London is the world's market for it. It is usually sold there by auction.

Graphite production, which a few years ago held promising hopes from several new mines and mills, has been a great disappointment. It has fallen to negligible importance.

During 1914, an average of 6756 men were employed in the mines, quarries, mills, and concentrators of Quebec, compared with 8611 during 1913. Of this number, 3116 were employed in mines, where nine deaths occurred. This is equal to 2.84 fatalities per 1000 men, as against 3.19 in 1913.

The larger mineral operations of Quebec are for the most part controlled by Americans in New York or Boston. In addition are a number of local companies engaged in mining. Labor conditions and railroad facilities are good. In a geological way, a variety of minerals are known to occur in the old pre-Cambrian formations of the province, but there is also a seeming tendency for the deposits to be pockety and irregular.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Utilization of the water supply in the mining districts of the Yukon Tanana region is one of the important elements in reducing the cost of mining. The water supply is not only used directly in placer mining, but is also of importance to the lode-mining industry in supplying power. During the period from 1907 to 1912 the engineers of the U. S. Geological Survey were engaged in measuring the streams in the various placer areas of the region, especially in the Fairbanks district. The results of this investigation have been published annually. They are now summarized and discussed in a volume recently issued, entitled 'Surface Water Supply of the Yukon - Tanana Region, Alaska, from 1907 to 1912,' Water-Supply Paper 342, by C. E. Ellsworth and R. W. Davenport.

Juneau

The first unit of the Alaska Gastineau mill treated 57,000 tons in April. During the last 10 days of the month the average was 2159 tons per day. Residue was 5c. per ton lower than in March. Costs were about 12c. lower. The ore is increasing in value. Construction of the other units of the plant is being hurried. Transport and tramming charges were lower. By July 1 the reservoir should be filled. No. 2 unit at No. 1 power-house is complete. The Salmon Creek division is practically finished. Preliminary work has been started on the Annex Creek scheme. The railroad is easily handling the tonnage required. In one 8-hr. shift two trains hauled 3500 tons. Underground work is confined to preparing stopes. The caving system of mining is a success. One stope on No. 5 level has yielded 350 tons per machine-shift for two months. In April 106,986 tons was broken, of which 61,912 tons was trammed to the ore-ways. Stoping costs are satisfactory.

Recent telegraphic advice states that the Gastineau mill is treating 2420 tons per day, one day's run being 2644 tons.

April returns from the mines on Douglas island were as follows:

Results.	Mexican.	Treadwell.	United.
Stamps working	120	540	270
Ore crushed, tons.....	18,830	75,212	43,799
Concentrate cyanided, tons.	446	1,653	953
Total gold recovered.....	$33,932	$140,279	$88,507
Profit, construction deducted	$8,850	$43,376	$22,069
Average per ton.....	$1.80	$1.86	$2.02

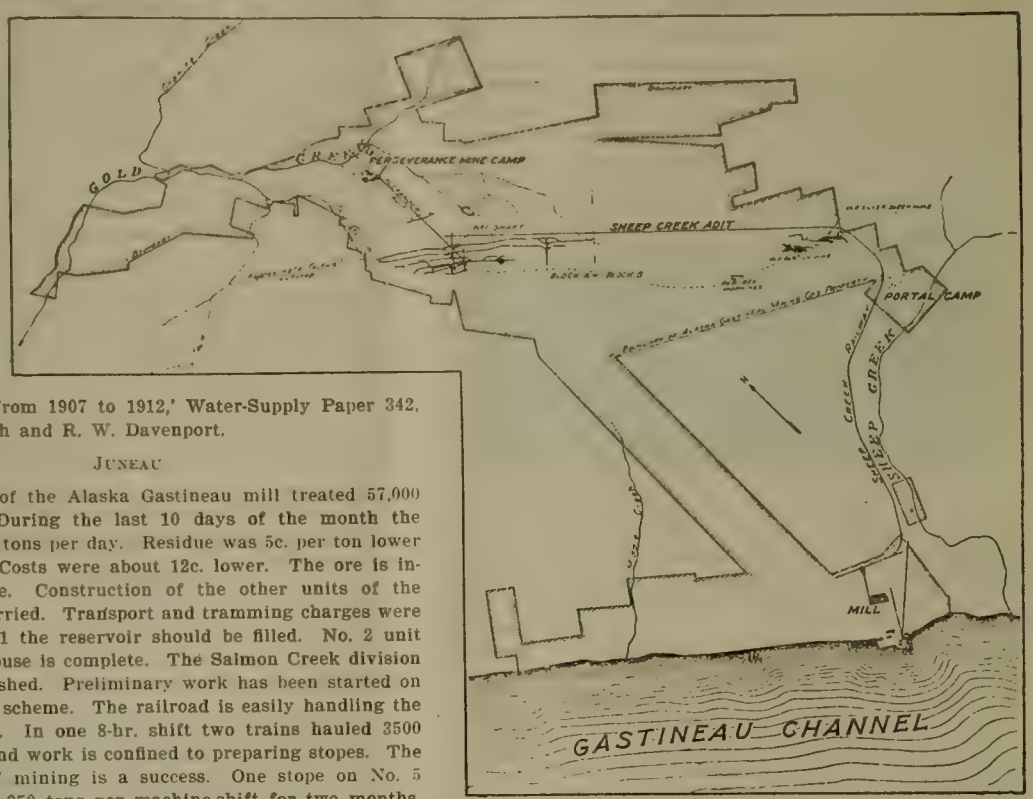
The reports of these companies for 1914 should soon be available for review.

A good seam of lignite has been discovered at the south end of Admiralty island, 40 miles from Juneau, by J. C. Hyde, C. Gundlach, J. Sandman, and P. Carlson. They are now preparing to develop the deposit.

ARIZONA

Cochise County

A large amount of copper ore has been developed in the Swisshelm Mountain Mining Co.'s claims, six miles from McNeal, on the El Paso and Southwestern line. An 1100-ft. adit has been driven. Four to 14% ore was opened. More machinery is to be ordered. Shipments may start in 90 days. High copper prices are adding to Bisbee's prosperity.



LOCALITY MAP OF ALASKA GASTINEAU PROPERTY.

Gila County

While the water on No. 12 level of the Old Dominion is decreasing slightly, it is still about 7,000,000 gal. per day. A new waste-conveying system is at work at the A shaft. The concentrating plant is treating 600 tons per day. The three turbo-generators have been overhauled. During May the smelter averaged 45 tons of copper per day. The basic-converter installed in July 1913 is still producing all the metal.

Mohave County

(Special Correspondence.)—As mentioned in the *Press* last week, the United Eastern Mining Co. has decided to erect a treatment plant. Ore above the 565-ft. level is estimated to be worth $2,000,000. A lode 37 ft. wide has been opened at this depth. It is all of profitable grade. At 300 and 460 ft. the lode is 23 and 40 ft. wide, respectively. The ore is oxidized and amenable to simple treatment. A main working shaft is to be sunk. Ample water will be available for the plant.

A 60-hp. engine, 375-cu. ft. air-compressor, 22-hp. hoist, jack-hammers, and drill-sharpener have arrived at the United Western mine. This adjoins the Eastern. The incline shaft has been straightened and enlarged. It will be sunk to 400 ft. A 40-ft. head-frame is being erected.

Oatman, May 24.

At 400 ft. in the Copper Prince at Swansea, which was closed two years ago, the lessee has opened a fair tonnage of 7 to 15% ore.——Prospectors from the Big Bend district brought a number of nuggets into Kingman last week. Some sluicing of the gravel is to be started soon.

CALIFORNIA

April oil production statistics include the following: rigs completed, 15; wells drilling, 138; completed, 33; abandoned, 11; producing, 5884; daily average, 244,563 bbl.; total output, 7,336,900 bbl. The increase over March was 460 bbl. per day. Stocks total 59,770,789 barrels.

Amador County

The 2400-ft. level of the Bunker Hill mine has been re-timbered. Rises are to be driven to connect with the 2200-ft. level. This will improve ventilation and make more ore available for the mill. Hardinge mills are to be installed in the plant.—— T. Jenkins is to operate the Monte de Oro mine on a royalty basis.——At the Central Eureka 30 of the 40 stamps are crushing. Sinking below 3100 ft. is soon to start. J. E. Davis is superintendent.

Butte County

At Forbestown, W. Lewis of Los Angeles has five stamps crushing ore from the William Beik mine. The equipment is to be enlarged.——In the Stirling district, situated in the mountains, there is increased activity as the snow melts.—— A road is being constructed to C. C. Antram's mine.

Nevada County

(Special Correspondence.)—Rich ore was found on May 25 in the Union Hill mine at Grass Valley, in a rise 25 ft. above the 800-ft. level, 130 ft. west of the main shaft. Bunches of rich ore were cut in the west drift after passing a reverse dipping vein containing no gold. The rise was started where the ore was richest. At a height of 25 ft. the rise cut a slip extending horizontally into the foot-wall. Here 30 in. of specimen ore was disclosed. After picking down as much of the quartz as could be loosened, a light charge was blasted. The hole made showed free gold on all sides, with 36 in. of rich quartz in the back, following the regular dip of the vein. The flat portion of the vein yielded several candle-boxes of ore valued at $5 to $10 per pound. This part of the mine has never been prospected below the 300-ft. level, although it produced a great deal of high-grade ore in the old workings near the surface. The mine, which is a consolidation of the Union Hill, Lucky, and Cambridge mines, is bonded to a San Francisco company named Union Hill Mines, of which G. S. Johnson is president and manager. The company is operating 15 of its 20 stamps on ore from this development, and a shoot which was opened 200 ft. east of the shaft, and 130 ft. above the 800-ft. level.

San Francisco, May 25.

Shareholders in the Pennsylvania Con. company have received $3 per share, over $200,000, as part payment for their shares, sold to the Pennsylvania Mines Syndicate, which owns the Empire mine adjoining the Pennsylvania.——A good development has been made at 400 ft. in the Montana mine, two miles from Nevada City. The Willow Valley Mining Co. owns this and other claims. Work is to be extended. The mill is to start soon. ——The Golden Center of Grass Valley has acquired the Peabody mine on Gold hill. This company now controls about 130 acres.

The new 60-stamp mill at the Empire mine has been accepted by the company from the contractor, Robert Hathaway.

Placer County

The old Larkin mine, two miles south of Placerville, was sold last week to C. F. Becker, of Sacramento, acting for San Francisco people. The Selby mine adjoining has been bonded to Eastern capitalists. It has been opened to 240 ft. Included in this deal is the Peacock copper mine.——Rich ore has been cut at 500 ft. in the Pacific mine at Placerville. There has been a change in lessees operating the property. Five stamps are working.

Sierra County

Construction of a new stamp-mill at the Plumbago to replace the one burned some time ago, is under way, in charge of Robert Hathaway of Nevada City.

Siskiyou County

Ore dumps made at many mines in this county about 50 years ago are now being profitably worked.

COLORADO

Clear Creek County

The remodeled mill at Idaho Springs is receiving plenty of ore for treatment.——A 20-ton lot from a new development in the Waldorf at East Argentine returned 1.53 oz. gold, 67.1 oz. silver, 12.85% copper, and 8.05% lead, a total value of $91.94 per ton. Lessees are doing well. The mill is closed on account of water supply. About 1500 tons of ore awaits treatment.——$65 to $75 ore is being extracted from the Santiago adjoining.——Lessees at the Capital are getting good results.

Dolores County

Lessees at Rico mines are meeting with satisfactory results. Among the properties being developed are the William J. Bryan, Hiawatha, Emma, Ocean Wave, St. Louis, Rico Wellington, and Rico Consolidated. The last named is a well-known regular producer.

Gilpin County

Rich gold-silver ore is being mined by the Bates Leasing Co. at Black Hawk. So is the Cashier Gold Mining & Milling Co. from the Pittsburgh mine. The latter also contains copper. Hutchins and Roberts, lessees at the Old Town mine, have had good settlements from their gold-silver ore. The Eureka is developing well.

Gunnison County

The Doctor zinc mine near Aspen is being developed by lessees. Results are very encouraging. As soon as a market is available a daily output of 100 tons can be maintained. Thirty per cent ore was recently opened in an adit.

Lake County (Leadville)

Lowering water in the Penrose shaft is resulting in a recession in mines on Fryer and Carbonate hills. The level in the latter is several feet lower.——The zinc smelter is receiving plenty of carbonate ore.——Another 30-ton shipment of oxide has been made, making three to date. The best carbonate ore is coming from Fryer Hill mines.——The Garbutt is producing 50 tons of $15 ore daily. A wide lode is being worked. Plans are nearly complete for the new mill.——Ibex lessees are mining a heavy tonnage of ore.——The Jennie June shaft, in the East Tennessee district, is down 265 feet.

Teller County (Cripple Creek)

On May 24 the Elkton Con. distributed 2c. per share, totaling $50,000. The amount for the current year is $100,000.——The Co-operative Mining, Milling & Leasing Co., which has a 20-year lease from the state on school section 16 on Bull hill, is to extend its development. A sub-lease is held by another syndicate. The main shaft is down 800 ft. Total gold yield is about $700,000.——McGillvary and partners, lessees at the El Paso, have opened some rich ore. The company's new hoist is working.——Four cars of about $1200 ore has been shipped from the Cresson mine during the past 10 days.——In April, net earnings of the Golden Cycle Mining & Reduction Co. were

$62,000. The regular dividend of 2c. per share will be distributed on June 10.——El Paso made a profit of $3000. A loss has resulted for about a year.——At the Alpha and Omega claims of the Dig Gold company on Gold hill, the shaft has been enlarged, and a hoist and compressor erected. Part of the ground may be subleased. Large shipments are to be made from the Economic dump.

IDAHO

Blaine County

The Wilbert Mining Co. has issued a report for the year ended May 1, 1915. It operates in the Dome district, 40 miles from Arco. The mine produced 7522 tons of ore. Of this 6685 tons was milled, 657 tons shipped, and 180 tons stored. The ore averaged 30.3% lead and 2.5 oz. silver, and 55.81% lead and 8.69 oz. silver, respectively. The shoot on No. 4 level is 190 ft. long, averaging 30 in. wide. On No. 5 it is 110 ft. long, of high grade. The mill operated less than five months. The lead market was responsible for this. Recovery was 80.7% lead and 83% silver. The plant will resume on June 1. Including an assessment, boarding-house, and other income totaling $23,758, the revenue was $109,871. Cash on hand amounts to $3342.

Shoshone County (Coeur d'Alene)

The Interstate-Callahan company has for some time been looking for a mill-site. A 36-acre tract between Enaville and the north fork has been acquired. Water-supply, tailing disposal site, and a railroad are handy. The company has issued a report for the quarter ended March 31. There was 25,430 tons of ore mined. Of this, 21,392 tons was milled. Concentrate produced was 808 tons lead, containing 25.16 oz. silver and 57.24% lead; and 9369 tons zinc, assaying 49.8% zinc. Crude ore shipped was 106 tons lead and 2200 tons zinc. All shipments totaled 12,483 tons. Total charges were $4.172 per ton. The net profit from $529,610 of products was $400,253.

The Success Mining Co. expects to make a profit of $90,000 in May. Probably the dividend for June will be 3c. per share. The mine produces zinc ore.

On June 4 the Bunker Hill & Sullivan company paid dividend No. 213, of $81,750. The total to date is $16,200,750.

MICHIGAN

The Copper Country

There are about 17,000 men employed in this region at present.——At the White Pine the shaft is down 1100 ft. on the incline. The lode is widening on lower levels. The daily output is 400 tons. About 700,000 lb. of mineral is ready for the smelter.——Tonnage from the Osceola in April was the largest in years.——Steel rods are being used in a mill at the Quincy in place of pebbles. This is an experiment.——The Franklin is sending over 200 tons of ore per day to the mill. The output is to be increased to 300 tons.——Mass is milling 1200 tons daily.——At 900 ft. in the New Arcadian the ore is better than in other parts of the mine. The shaft is being sunk to 1050 ft. ——One stamp at the re-built Isle Royale mill is nearly ready to crush.——Two more furnaces have been blown-in at the C. & H. plant at Hubbell.——The Copper Range Consolidated is organizing first-aid and safety crews at its properties, the Baltic, Champion, and Trimountain. Mass copper is being extracted from the last named. A five-year working agreement has been arranged between the Hancock and Quincy companies. The former can use No. 7 shaft of the latter during specified hours, also extract ore which the Quincy has proved to exist in Hancock ground. The Quincy buys 75 acres of land from the Hancock at a depth of over 5000 ft. for $191,000 It would be 15 years before the Hancock could reach this area. Two hundred men are to be added to the force.

MISSOURI-KANSAS-OKLAHOMA

According to C. A. Wright of the U. S. Bureau of Mines, tests show that mills in the Joplin district recover only from 65 to 70% of the zinc. He advocates systematic experimenting to increase this result and has prepared a paper on the subject.

Heavy rain interfered with small operators in the region last week. The output was as follows:

Ore	Week	21 weeks
Blende	10,333,100	211,606,680
Calamine	392,080	16,473,475
Lead	1,842,750	33,393,330

Average value last week was $70.15, $42.31, and $50.78 per ton respectively.

Zinc ore producers last week were gloomy, as no quotations were being made for their product. A shut-down of many mines was feared.

A 300-ton mill is being erected for the Onamena Mining Co. at Duenweg. Drilling has revealed a good deal of ore.

MONTANA

Silverbow County

Nearly all of the Anaconda company's mines are now working six days a week.——The Washoe smelter has too much ore on hand, and the St. Lawrence, Badger State, and Poulin

BUSINESS PORTION OF BUTTE, LOOKING NORTH.

mines have been closed temporarily.——The Butte & Superior company is to sink a large shaft. It will be equipped with a powerful hoist. Results at 1300 and 1500 ft. in the Black Rock claim are very satisfactory.——Both of the above companies have raised miners' wages to $4 per day.

NEVADA

Esmeralda County

The downward extension of the new orebody in the Jumbo Extension has been opened by a rise from the 952-ft. level. The ore in the rise is worth $83.90 per ton. This is 64 ft. above the level. The shale formation is broken up.——On July 31 the Goldfield Consolidated will pay 10c. per share.—— Since May 15 the Goldfield Atlanta has sent 80 fifty-ton carloads of $30 ore to the Western Ore Purchasing Co.'s sampler.

Humboldt County

No. 2 bullion shipment from the Rochester mill was worth $25,000. The railway is to be extended to the plant, three miles from the present terminus.

Lyon County

At the Rockland mine the new mill has started. E. J. Schrader is general manager.——Lessees at the Empire-Nevada have sent 100 tons of 5.88% copper ore to the Hazen sampler.——The Nevada-Douglas company is busy at its Western Nevada mine. A shaft is down 500 ft. Cross-cuts at 100, 200, and 300 ft. have opened a fair tonnage of ore.

Owing to the metal market, the Mason Valley Mines Co. shut down its mines and smelter near Thompson in the third week of October 1914. The report of the general manager, Jules Labarthe, covers the year 1914. A geological examina-

tion was made of the property during the period. Most of the development was done on the east orebody, which, while not as large as the main shoot, will produce a considerable tonnage. The shrinkage system of stoping gave good results. On properties adjacent to the smelter a great deal of prospecting was accomplished, leases and options being secured. Smelting costs were reduced, and the stoppage on October 20 was the first interruption since January 6, 1912. Ore from Shasta county, California, was being treated up to the time of closing. Future smelting operations are dependent on the stability of the copper market, the available tonnage of customs ore, and the development of the Mason Valley property. Further opening of copper ore at Goldfield should also help the smelting situation.

In 9¾ months the smelter treated 75,038 tons of company, and 61,159 tons of custom ore, a total of 142,197 tons. This yielded 9,127,974 lb. copper, 11,553 oz. gold, and 221,151 oz. silver.

Financial results were as follows:

	1914.	1913.
Sales of copper, gold, and silver	$1,708,801	$2,809,919
Cost of metal sold	1,608,094	2,526,644
Operating profit	$100,707	$283,275
Other income	5,607	5,037
Total income	$106,314	$288,312
Selling cost, Federal tax	75,458	82,408
Net profit	$30,956	$205,904
Bond interest, etc.	71,130	85,340
Deficit	$40,174	*$120,564
Previous surplus	347,461	226,897
Final surplus	$307,287	$347,461

*Surplus.

Nye County

Shareholders of the White Caps Co. of Manhattan have decided to have a reorganization. The new company will be known as the White Caps Mining Co. It will have a capital of 2,000,000 shares. An assessment of 1½c. per share will be made.——The War Eagle 20-stamp mill has been treating ore from the Little Grey for 10 days. Amalgamation and cyanidation will give a good recovery. A good deal of ore has been opened.——A new Gates crusher is being installed at the Mushett-Wittenberg mill. These people have obtained a lease on the Consolidated. The ore will be treated at the Manhattan Milling & Ore Co.'s plant.——More specimen ore has been extracted from the April Fool claim.

Seven mines and lessees at Tonopah last week produced 11,001 tons of ore valued at $223,978.——The sweeping of the valuable salts that form a crust on tailing dumps at Tonopah mills has kept a fair number of men busy for some years. Most of the product has been sent to smelters, but transport, treatment, and losses are high. The Nevada Securities Co. has been formed to use a new process for the sweepings. The MacNamara mill is to be leased, with J. B. Tregloan in charge.

OREGON

Ores and minerals from Oregon are on view at the Exposition. They will be soon described in this journal.

The University of Oregon, at Eugene, has planned work for the summer. Graham J. Mitchell, of the geological department, and B. S. Butler, of the School of Mines, will study Curry county. Warren D. Smith, head of the department, will examine the stratigraphy of the west slope of the Cascades. These investigations are for the Oregon Bureau of Mines and Geology. A field class will be held at Crater lake. Next year the department of geology will occupy new quarters. New equipment is to be added to the laboratory.

Josephine County

(Special Correspondence.)—Since it has been definitely decided that Twohy Bros., of San Francisco, will take over the California & Oregon Coast railway, 11 miles long, and will build the line as far west as Takilma, 40 miles, in the Waldo copper district, there has been a marked improvement in mining operations of western and southern Josephine county. Especially is there an increase of interest in copper and low-grade gold quartz. There are a number of low-grade properties in the Kerby, Waldo, and other districts, that only require railroad transport to be profitable.

C. E. Tucker, the former superintendent of the Takilma smelter, has secured a lease on the Queen of Bronze copper claims in the Waldo district. He has miners at work and will ship ore to the Kennett smelter, California. Auto-trucks will be used for hauling ore from the mines to Grants Pass. Six hundred tons of ore is now in the bins at the mines, ready for shipment. A large amount is in reserve.

A. C. Epperly, manager of the Columbia hydraulic mines, of Grave creek, states that the final clean-up for the season will soon be made. Though the Columbia is one of the oldest placer mines in Josephine county, it has an extensive area yet to be sluiced. The output will be up with the high average maintained for the past 20 years. Portland men are owners of this mine. L. A. Lewis is president.

W. J. Huselton, manager of the Wyoming placers on Tennessee gulch, near Kerby, says that cleaning-up is now in progress. Though the water supply was cut short, owing to lack of snow in the mountains, the richness of the ground worked brought returns up to the usual mark.

Grants Pass, May 20.

UTAH

It is stated in Salt Lake City that Utah and Nevada zinc producers may form an association to aid the mining of this metal. Although spelter is high, many mines cannot sell their product, smelters fixing a high basis for ore shipped, as much as 40%. This matter is discussed editorially in this issue.

Beaver County

The Horn Silver Mining Co. has issued a report for the year ended December 31, 1914. Seventy men were employed. The mine has been opened to 1000 ft. Ore reserves are about 10,000 tons. The output was 24,121 tons worth $163,979. Lessees mined $37,184 also. The profit was $13,178. The surplus at the end of 1914 amounted to $76,240.

Juab County

The leasing system may be tried at the Chief Con. mine. At other mines in the Tintic district it has resulted profitably to all concerned. The company is to diamond-drill an area east and north of Eureka.——Rich lead-silver ore is being opened at and below 1700 ft. in the Eagle & Blue Bell.——From its output of zinc ore the May Day is making a fair profit. A dividend of 3c. per share was paid last week.

Washington County

Considerable excitement prevails regarding the new district of Goldstrike. The township is 38 miles south of Modena, which is on the main line of the Salt Lake 'Route.' A regular passenger and freight service has been started. The return fare is $10. Freight costs 1¼c. per pound. A number of companies have been organized to prospect the area. The May 15 issue of *The Salt Lake Mining Review* contains an illustrated description of Goldstrike. The climate is good, the altitude being 5000 ft. There is plenty of timber available, also a good supply of water. The Bull Valley company holds 15 patented claims. It has driven over 2200 ft. of adits, cross-cuts, and rises. Part of the property has been leased. The Goldstrike Mining & Development Co. has a 3-stamp mill and gasoline engine at work. Working costs should be low. Mining can be done by means of adits. The ores are free-milling. The country rock is limestone, cut by porphyry dikes. A good deal of trenching and other prospecting work has been done.

WASHINGTON

OKANOGAN COUNTY

In the Twisp district the Montana mill is shipping bullion regularly. The mine contains a fair tonnage.

STEVENS COUNTY

New machinery has been erected at the Security Copper Co.'s mine at Chewelah. Six veins have been opened. Shaft-sinking is under way. L. K. Armstrong is in charge.

CANADA

BRITISH COLUMBIA

At Three Forks the Rambler-Cariboo mill is treating about 2000 tons of zinc-lead ore per month. Concentrate produced is from 175 to 200 tons of zinc, and an equal quantity of lead. From 30 to 60 tons of crude lead ore is shipped each month. At 1200 ft. in the mine there is a shoot of zinc ore 5 ft. wide and 40 ft. long. Ore reserves are estimated at 9200 tons in the mine. W. A. Cameron is in charge.

ONTARIO

At the Porcupine Crown the 19,000 tons of tailing from the old plant is being treated. It averages $3.50 per ton. A profit of $30,000 is expected. Dividend No. 6 will be paid on July 2. Work has been resumed at the Keeley mine, South Lorrain.

A new vein, 4 in. wide, assaying 2000 oz. per ton, is being opened in the south end of the Coniagas No. 4 shaft, at No. 4 level. This shaft is at one of the busiest corners of Cobalt. ——On July 1 the McKinley-Darragh company will distribute 3%, equal to $67,431. The total is 202%, and $4,539,571.

YUKON

On May 7 the Yukon Gold Co.'s dredges were ready to start the season's work. In 1914 they commenced on May 11. The hydraulic plants were also ready. Chester A. Thomas, E. E. McCarthy, George Coffey, Warren McFarland, and R. E. Franklin are in charge of the various departments.——About 1500 tons of silver ore is being hauled from Galena creek to Mayo, for shipment to smelters.

KOREA

The Oriental Consolidated company reports that in March 180 stamps crushed 23,500 tons of ore. Revenue from all plants totaled $155,326. The net profit was $79,520.

MEXICO

SONORA

A three-ton Packard auto-truck is to replace mules for carrying supplies to El Tigre mine.

The report of the Greene-Cananea Copper Co. for 1914 has been issued. It contains the following information: The mines contain more and richer ore developed than for years. Owing to the revolution in Mexico the mines and works worked irregularly. On August 15 they were closed indefinitely. The property is in good order. There was 384,690 tons of ore mined at a cost of $3.09 per ton. Development totaled 31,859 ft., at 65c. per ton. This is included in mining. One unit of No. 2 mill treated 147,394 tons. Copper output was 20,131,317 lb. The total income was $3,852,998. All expenditure, including depreciation of $160,071, amounted to $3,237,206. The net profit was $615,792. In 1913 the income was $6,139,917 and profit $2,186,260. Dividends totaling $1,000,000 were paid. The year started with balance of $5,012,581 and ended with $4,628,373. The net cost of producing copper was 10.6c. per pound.

The MINE INSPECTORS' INSTITUTE OF THE UNITED STATES OF AMERICA will hold its eighth annual meeting at St. Louis on June 8, 9, 10, and 11. Subjects to be discussed are uniform mine legislation, shot-firing advantages, prevention of ignition of coal dust when black powder is used, and how accidents from roof-falls may be reduced. J. W. Paul is secretary at 40th and Butler streets, Pittsburgh.

PERSONAL

W. A. CLARK is at Jerome.

D'ARCY WEATHERBE is at Toronto.

EDWIN E. CHASE is at Silverton, Colorado.

W. H. LANAGAN has gone to British Columbia.

J. H. BAKER is at Jerome on his way to Mexico.

BERNARD MACDONALD is here from Los Angeles.

CHARLES A. VAN ZANDT is here from New York.

LLEWELLYN HUMPHREYS has returned to Los Angeles.

JOHN B. FARISH is expected in San Francisco about June 22.

C. V. DREW has returned to New York from Cerro de Pasco.

E. M. HAMILTON has arrived in San Francisco from London.

ARTHUR S. EAKLE is engaged in geological work in Alpine county.

GEORGE H. GARREY has completed his geological work in Nevada.

W. W. BARNETT is engineer and assayer to the Ellamar Mining Co. in Alaska.

EDGAR A. COLLINS is taking a short holiday on the Klamath, in northern California.

LEON F. LE BRUN has been appointed superintendent for the Neville Free Coinage Mines at Cripple Creek.

W. L. CLARK, manager for the United Verde Copper Co. at Jerome, started the new smelter at Clarkdale, Arizona, on May 26.

GEORGE O. BRADLEY, CHARLES E. BRUTT, and JULES LABARTHE have formed a partnership as engineers, with offices in the Hobart building, San Francisco.

LUIS O. ABELLI, Bolivian Commissioner to the Panama Exposition, will represent the Department of Mines and Metallurgy on the Superior Jury of Awards.

THOMAS T. READ has been elected chairman of the Department Jury on Mines and Metallurgy at the Panama-Pacific Exposition, and will represent that department on the Superior Jury, which convenes this week to make the final award.

Obituary

LEWIS A. MERRILL, agricultural engineer for the Salt Lake Route and the Mammoth Copper Co., died at Salt Lake City on June 1, the result of injuries received in an automobile accident near Kaysville, Utah. He was well known in Utah from his connection with the Agricultural College.

D. A. LOUIS died in London on March 25 at the early age of 58. An energetic and clever man, widely traveled, and a good linguist, he will be missed from the ranks of the active members of our profession, but it is more as a genial comrade and a trusty friend that his passing will cause pain to busy men in many corners of the earth.

Schools and Societies

COLUMBIA UNIVERSITY held its commencement on June 2. There were 2160 graduates, a record.

The Colorado branch of the A. I. M. E. held a dinner and meeting at Denver on May 29. The Institute secretary, Bradley Stoughton, was present.

The UNIVERSITY OF UTAH held its commencement on May 30. A large number of degrees were conferred. Students from the geology department have been visiting Tintic with Hyrum Schneider, the instructor.

On May 28 the COLORADO SCHOOL OF MINES held its 41st commencement. Twenty-five graduates received the degree of E.M.; one received that of M.S. The theses written discussed many metallurgical problems.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, June 3.

Antimony	35 —35¾
Electrolytic copper	19¼ —19½
Pig lead	5.25
Quicksilver (flask)	$80.00
Spelter	22 —22¼
Tin	39½—41
Zinc-dust, 100-kg. zinc-lined cases	27

EASTERN METAL MARKET
(By wire from New York.)

NEW YORK, June 3.—Electrolytic copper is quiet, although the tendency is upward, lead is very strong, with an upward tone; the spelter market is uncertain and there are few sellers. June dividends are estimated at $114,000,000.

COPPER

Prices of electrolytic in New York, in cents per pound.

April returns were as follows: Anaconda, 20,500,000 lb. Chino, 5,027,548 lb.; Nevada Con., 1,710,684 lb.; Ray, 5,333,387 lb.; and Utah Copper, 12 015,148 lb. Estimates of Calumet & Hecla for May give 8,900,000 lb. Wages at Anaconda mines have been raised to $4 per day.

Dividends declared by copper companies are as follows: Ahmeek, $2.50; American Smelters Securities, 1½ and 1¼% on A and B stock; Calumet & Arizona, 50c.; Champion, $1; Chino, 75c.; Guggenheim Exploration, 4%; Nevada Con., 37½c.; Old Dominion, $1. Ray, 37½c.; and Utah, $1 per share.

Copper exports during the second week of May totaled 11,501,528 lb., worth $1,968,693. Quotations in London on June 2 were equal to 19½c. for electro at New York.

In 1914 the Granby company produced 23,320,097 lb. copper, 435,275 oz. silver, and 43,882 oz. gold. Ore reserves are estimated at 23,101,075 tons. The annual meeting was held in New York on May 18. No dividend was declared.

According to Henry R. Merton & Co., the world's production of copper in 1914 was 923,888 metric tons. In 1913 it was 1,005,978 tons. The United States contributed 525,529 tons. Japan was second with 68,058 tons.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date		Average week ending

May	58.21	49 87	Nov.	49.12	....
June	56.43	....	Dec.	49.27	....

The silver market shows weakness. Pixley & Abell, London, consider that on account of supplies any sharp advance is improbable at present. On July 1 the Tonopah Belmont will pay 12½c. per share for the second quarter.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 76 lb., are given below:

Reports from Boston state that there have been transactions at 27c. per pound. Last week ore was sold at Joplin for $85 per ton, basis of 60% metal. The weekly output is 5800 tons of concentrate and 500 tons of calamine. Reserves are about 7000 tons. Spelter in London is £95 per ton, or 23.75c. per pound. The Butte & Superior company has declared its quarterly dividend of 75c. and an extra dividend of $2.50 per share. The Interstate-Callahan will pay $1 per share.

Tin is quiet at 37.50 to 38c. per pound.

Eastern Metal Market

New York, May 28

Interest is almost entirely centred in the great rise in spelter prices and the far reaching effects of its scarcity. Nearby deliveries of prime Western bring 20 to 22c., and premiums are willingly paid for future deliveries. Never before have the producers been sold up so thoroughly, or so far ahead. Much talk is heard of finding substitutes for spelter. The copper demand has slumped for the time being, and concessions in price are possible on all sides. Consumption is unquestionably held back by the inadequacy of facilities for producing certain products. Makers of shrapnel, for instance, are having difficulty in securing copper tubes from which are cut the rings fitted to the base of the shrapnel-cases. The brass-sheet mills are loaded to capacity with orders for months to come. The price of lead has been advanced twice in the week, $2 per ton each time. Tin is weaker because of the extremely large arrivals, business has been quiet. Antimony has been in light request, but is scarce and the high prices hold. Aluminum is also higher and scarce.

In general business, the hoped-for betterment does not materialize very fast, although the railroads are doing a little more buying and the same is true of industrial plants generally. There is some waiting to determine if the country is to become involved in international complications.

COPPER

The market has been neglected by both domestic and European buyers. The lack of demand has developed pressure to sell on the part of second-hands. They have quoted down to 18.50c. cash, New York, and there have been reports that still less would be accepted. The producers, most of whom have been holding to 19c., 30 days, delivered, now show a tendency to make concessions. The situation is one where the brass and copper mills, which are filled with orders for practically the balance of the year, are covered for their immediate needs. The exports for the month are excellent, considering the conditions. The National Brass & Copper Tube Co., in its *Copper Gossip*, says:

"Consumption of copper in this country at present is enormous, and manufacturers are required to cope with conditions which are likely to call for enlarged capacity if demand continues to develop at the recent rapid rate. If purely industrial requirements should show a marked increase during the next six months the brass and copper mills may prepare for a record-breaking melting of copper. It will not be surprising if this country will soon consume more copper annually than at any time in the past."

Today the market gained some strength, and 18.62½c. was quoted.

SPELTER

A wild scramble to buy spelter has sent prices up with a rush to levels which exceed the price of electrolytic copper, which, needless to say, breaks all records. Prompt metal is now quoted at 21 to 22c. Ordinary differentials between positions, and prices, East and West, have been more or less disregarded in the haste to buy. Forward deliveries as well as nearby shipments are commanding premiums, and little is to be had at the high prices. Business has been done into next year. Never before have the producers and sellers been in such a tight position. Some of the transactions have been large. The scarcity caused activity to taper off this week. Ordinary prime Western spelter, spot delivery, commands 22 to 23c., if it can be found; June ranges between 20 and 21c. The average for fourth quarter delivery is about 18.50c., and for delivery in the first quarter of 1916 the quotations range from 17c. upward. Sellers have been obliged to decline business. It is reported that one company last week sold 3,500,000 lb. for delivery running late into the year, at prices ranging from 16.25 to 20c. The latter was paid for choice grades. Since then prices have advanced steadily.

The scarcity and consequent high prices, coupled with the sold-up condition of the mills, has had a most serious effect on brass and copper products. The American Brass Co. has withdrawn its prices, as mentioned in the *Press* last week. Orders for hundreds of tons of sheet-brass cannot find acceptance. For ordinary yellow or Muntz sheets, 25.50c. has been asked, and 24 and 25c. has been paid for brass-rods. Jobbers whose stocks are replete are reaping a harvest, and the small consumer does not know what to make of it. The mills seem particularly averse to considering export orders. The causes of the situation may be summed up as follows: the enormous demand for cartridge metal and other metal for munitions of war, while the combined foreign and domestic demand exceeds production. Manufacturers of war materials at first though they must have high-grade spelter, but when that became scarce they have turned to ordinary grades and found that it does not carry an excessive amount of impurities into the finished products. There is much talk of substitutes for spelter, and for the products into which it enters. Black sheets coated with tin and lead are cheaper today than galvanized sheets, while painted sheets are a common substitute. If the present trend continues it is believed that recourse will be had to copper sheets for purposes where the price has heretofore been prohibitive. As for sheet-zinc, aluminum sheets can now be sold at a lower price. The base price of sheet-zinc has been advanced to 22c. by one of the large interests.

LEAD

The surprise of the week was an advance of $2 per ton, or 10c. per 100 lb., making the quotation 4.30c., New York, May 26. Up to that time the market had been quiet. The advance stimulated buying, and on May 27, there was another advance announced by the large interest, also of $2 per ton, making the New York quotation 4.40c. per pound. On May 28 there was a further advance to 4.50c. New York. It appears that domestic consumers were well covered, but there were some good-sized inquiries in the market which hung-fire. The independents were apparently unable to take care of them, as they are comfortably filled with orders. Subsequent to the last two advances referred to the independents advanced their St. Louis price to 4.32½c., then to 4.42½c. Exports have been good.

TIN

The market has been almost uniformly quiet, heavy arrivals have put a quietus on all fears of a shortage for the time-being. The trend of the market has been steadily downward, which was to be expected, in view of the plentiful supply. There have been days of good buying, but the quiet ones were more frequent.

ANTIMONY

The market has been quiet. The situation is not changed with regard to English brands. They are unobtainable and therefore not quoted. Chinese and Japanese are quoted at 35 to 38c. Owners of deposits of antimony ore are seeking financial backers; but it is a question how successful they will be in view of the fact that the present abnormal condition will pass with the end of the War.

ALUMINUM

Buyers are casting about, but with poor success, to buy sheet aluminum through other than the ordinary channels. Sheets are nominal at 31 to 32c. The metal is scarce and prices have advanced from 25.50 to 26c. for 98 to 99% purity.

Current Prices for Oils and Candles

(Corrected monthly by Standard Oil Co., California.)

All prices are f.o.b. San Francisco except where otherwise specified, and are subject to change without notice.

Granite Mining Candles.	Per set, cents.	Granite Mining Candles.	Per set, cents.

PYRITE AND SULPHURIC ACID IN 1914

Production of the above has just been published by the U. S. Geological Survey. The pyrite output was 336,662 long tons worth $1,283,346. This is a small decrease compared with 1913. Virginia is the leading producer. Imports totaled 1,026,617 tons, an increase of 176,025 tons. Sulphuric acid production amounted to 3,762,417 short tons of 50° acid, valued at $24,163,331. This does not include 21,993 tons of fuming acid worth $316,596. Copper and zinc smelters made 950,798 tons valued at $5,190,293.

COMPANY REPORTS

RAY CONSOLIDATED COPPER COMPANY

This company's mine is at Ray, Pinal county, and mill at Hayden, Gila county, Arizona. The report covers 1914.

Development tributary to the three main shafts amounted to 75,261 ft. Total to date is 452,233 ft. Mining operations have destroyed 182,760 ft. of this. Re-calculated ore reserves amount to 74,765,789 tons, averaging 2.214% copper. There was extracted 2,426,739 tons of ore, containing 1.760% , also 2591 tons of 11.867% ore. Mining costs were 62.42c per ton, a reduction of 10.81 cents.

The mill concentrated 2,427,700 tons, with 67.88% recovery, at a cost of 49.88c. per ton.

Concentrate and ore smelted yielded 59,044,700 lb. metal. The net cost of production was 8.763c. per pound.

Revenue from copper, gold, and silver was $7,597,724. Operation cost $5,281,484. Adding miscellaneous income to the operating profit, there was available $2,655,163. Interest reduced this to $2,395,623. Dividends paid amounted to $1,089,322. At the beginning of the year the surplus was $2,758,126; at the end, $3,776,368.

CHINO COPPER COMPANY

This company's excellent report for 1914 contains the following information:

A little drilling was accomplished for development purposes. Including the ore proved in the South body, reserves are estimated as 90,270,155 tons, averaging 1.75% copper. Further drilling should add to this total. Overburden removed amounted to 3,173,717 cu. yd. The steam-shovels also mined 2,114,910 tons of ore. Mining cost averaged 36.52c. per yard. The new coarse-crushing plant near the mine reduced the cost of shoveling ore.

From August to the end of the year the mill was operated at 66% capacity. A total of 1,907,300 tons of ore was treated during 1914. This averaged 2.1151% copper. Concentrate produced was 147,925 tons. Including 2,093,723 lb. metal in 19,405 tons of ore sent direct to the smelter, the year's output was 56,841,977 lb. Milling cost 55.01c. per ton, a decrease of 6.07 cents.

Metals sold realized $7,247,197. The net profit was $3,222,579. Dividends amounted to $2,169,065. The year started with a balance of $3,743,167, and ended with $4,566,402.

NEVADA CONSOLIDATED COPPER COMPANY

The eighth annual report of this company, covering 1914, contains the following data:

Prospecting with churn-drills was continued on the west side of the Ruth orebody, on the Kearsarge and Eclipse claims, and in the Liberty pit north of the 'clastic' dike. Thirty-four holes were drilled a total depth of 13,160 ft. Ore reserves at the end of 1914 were estimated at 41,020,296 tons, averaging 1.68% copper. Of the 2,636,535 tons of ore mined, only 123,324 tons was from underground work. Overburden moved amounted to 3,044,966 yards. Steam-shovel mining cost 15.17c. per ton. In 1913 it was 17.75c. Stripping cost 31.71c. per yard.

The mill treated 2,640,294 tons of ore averaging 1.483%. The recovery was 68.48%. Reverberatory furnaces reduced 515,162 tons of concentrate, ore, slag, etc. Converters produced 50,542,542 lb. copper. Custom ore yielded 1,298,486 lb. Costs averaged 8.91c. per pound of metal.

The revenue was $7,052,499; operating expenses, $6,335,522; profit, $716,977; miscellaneous income, $1,046,044; available for dividends, $1,763,021; distribution, $2,249,389; balance end of 1913, $3,069,643; and balance end of 1914, $2,290,626.

MINING DECISIONS

Mining Partnership—Effect of Dissolution

Where several co-lessees are working a mine for their joint interests they are mining partners within the contemplation of the law. Where one of said co-lessees withdraws from said work and ceases to contribute to the cost of the same, he ceases to be a partner and his former co-partners cannot continue to operate at any expense to him.

Lamont *v.* Reynolds (Colorado), 144 Pacific, 1131. December 14, 1914.

Overlapping Leases and Sale of Royalties

Overlapping leases and the sale of royalties in the Oklahoma lead and zinc field are contrary to law, and henceforth will not be tolerated. This is the substance of a decision handed down by the Supreme Court of the United States. It is of extreme importance to every mining operator in the Miami field, where so much development work is being carried on right now. The Joplin letter of May 8 discusses this subject.

Eminent Domain—Value of Mineral Rights

Where a power company condemned a right-of-way for the erection and maintenance of a transmission-line, and acquired only the use of the surface of the land taken for such right-of-way, the owner can recover only the value of the surface taken unaffected by the value of any minerals that may be underneath the surface.

Alabama Power Co. *v.* Keystone Lime Co. (Alabama), 67 Southern, 833. January 11, 1915.

Forms of Contracts *re* Oil Lands in Withdrawn Areas

The Secretary of the Interior has issued a set of instructions and blank forms of application and contract, permitting persons who make application for placer patents to oil lands withdrawn from entry, to enter on such lands and drill for oil, on condition that they deposit one-eighth of the gross proceeds in escrow in a national bank. Such deposits are to be held by the bank until the Department of the Interior finally disposes of the application for patent. If said application is granted, the money is to be returned to the depositor. If the patent is refused, the money is to be delivered to the United States Treasury.

Instructions of November 20, 1914, 43 Land Decisions, 459.

Oil Lease—Lessee's Right to Select Well Locations

A land-owner leased to another the right to drill wells for the extraction of oil and gas. The lessee selected as a location for one of his wells a reservoir-site being prepared for use by the land-owner. Another site chosen was ground on which excavating for the foundations of a building had been completed. The lessor's superintendent prevented the lessee from carrying on drilling operations on either location, it appearing that there were equally advantageous locations near by which would not interfere with the lessor's plans. Held, that an injunction would not issue at the suit of the lessee to aid him in totally disregarding the rights of the lessor, where his own inconvenience was slight in comparison with the injury to the lessor which would result from the proposed drilling operations, and his damage if any would readily admit of compensation.

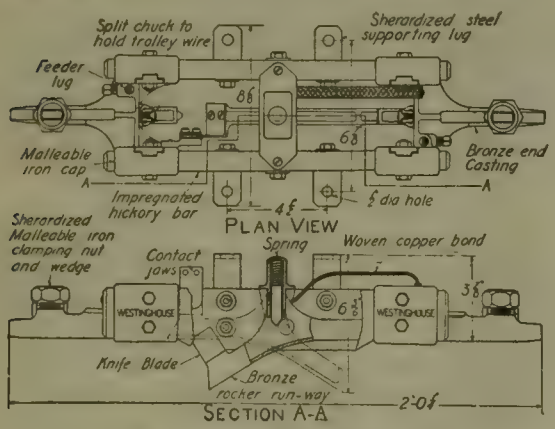
Gillespie *v.* American Zinc & Chemical Co. (Pennsylvania), 93 Atlantic, 272. January 2, 1915.

New Machines and Devices

Information based on letters and catalogues from manufacturers.

Automatic Section-Insulator

Patent No. 1,126,092 has been recently granted to William Schaake, of the Westinghouse Electric & Manufacturing Co., on an automatic section-insulator. These insulators are inserted in trolley-wires where it is desirable to energize a section when the trolley passes on to it, and to de-energize it when the trolley passes off. They are used extensively in mining in-



THE AUTOMATIC SECTION-INSULATOR.

stallation where a branch is to be energized only when the locomotive is on that branch. Leakage losses and dangers of contact by persons passing under the trolley-wire are thereby averted when the locomotive is not on the branch. Street-railway companies sometimes use them in the same way. The circuit is opened and closed by a switch-blade mounted on a rocker that the trolley operates. In one position the blade connects with copper-contactors. In the other there is no connection.

Commercial Paragraphs

The varied uses of BUCYRUS steam-shovels is further described and illustrated in *The Excavating Engineer* for May.

A pamphlet describing its instructive exhibit at the Exposition has been issued by the PELTON WATER WHEEL Co., San Francisco.

Book No. 210, 48 pages, of the LINK-BELT Co., Philadelphia, illustrates 'Link-Belt' wagon and truck-loaders. A large variety is manufactured.

The KELLEY FILTER PRESS Co. announces that it has moved its New York office from 80 Maiden Lane to the Hudson Terminal building, 30 Church street. Emil E. Lungwitz is in charge.

The SMOOTH-ON MANUFACTURING Co., Jersey City, New Jersey, will be pleased to send a copy of Pamphlet No. 4, on the use of its 'Smooth-On' water-proof mixture, to persons writing to the above address.

In *Leschen's Hercules* for May are described the foundations for the Harahan bridge, Memphis, Tennessee (the main bridge is 2550 ft. long); the Mill Creek storm sewer, St. Louis; the new third lock and canal at Sault Ste. Marie, Michigan; and lowering a 20-ton valve down a 250-ft. shaft. In all these operations LESCHEN'S wire rope was used.

The WILSON-SNYDER MANUFACTURING Co. and the WILSON-SNYDER CENTRIFUGAL PUMP Co., of Pittsburgh, Pennsylvania, have opened a branch office at 52 Vanderbilt avenue, New York, in charge of A. H. Sherwood.

'Marion Reliability and Your Profits' is the title of Catalogue 93 of the MARION STEAM SHOVEL Co., Marion, Ohio. The 48 pages describe and show the general use of shovels. Specifications are given with certain models.

In the May *Webster Method*, the WEBSTER MANUFACTURING Co., of Tiffin, Ohio, describes its installation of conveyors at the new smelter of the United Verde Copper Co., at Clarkdale, Arizona. Nearly 7000 ft. of belting was used in the plant.

Bulletin No. 60 of the WILFLEY MINING MACHINERY Co., London, describes the Hoover rapid laboratory sizer. This apparatus consists of a series of screens mounted in frames, made so that the tops and bottoms of adjacent frames fit into each other. The whole is suitably rotated. It is claimed that besides accuracy in screening, one-thirtieth of the time occupied in hand work is required.

The ROESSLER & HASSLACHER CHEMICAL Co., of New York, have an interesting little booth in the Palace of Mines and Metallurgy at the Exposition. It contains various chemicals, including sodium cyanide, cyanide chloride mixture, bichromate of potash, hyposulphite of soda, and permanganate of potash. A mechanical electro-plating apparatus is of interest. A picture at the back represents an alchemist at work.

The DODGE SALES & ENGINEERING Co., distributer of the products of DODGE MANUFACTURING Co., Mishawaka, Indiana, has just issued a new 125-page illustrated catalogue covering the full Dodge line of gearing. For a number of years the Manufacturing company has made a specialty of this class of transmission, and the line embraces many thousands of patterns and methods in a most complete manner for the general requirements of the trade.

Barometric jet-condensers are used at many steam plants. In Form No. 1001, the CRESSON-MORRIS Co., of Philadelphia, discusses the condensing plants it manufactures. Using the Beyer counter-current type the following advantages are claimed: high vacuum at exhaust of prime-mover; ability to vary quantity of cooling water in direct ratio to load of prime-mover, without impairment of vacuum; operation of vacuum under all conditions; low operating costs; and permissible use of dirty, gritty, or acid cooling water continuously, without necessity for cleaning or repair. Ingersoll-Rogler dry air-pumps are used with these condensers.

The INTERNATIONAL STEAM PUMP Co., of New York, sends information regarding a large pump contract awarded Henry R. Worthington by the Panama Canal Commission. This plant is for dry dock No. 1 at Balboa. The contract involves design, fabrication, and delivery on the Isthmus of the structural, mechanical, electrical, and hydraulic parts required for this installation. The pumps consist of four main units with a capacity of 11,000 cu. ft. of sea-water per minute, two drainage units of 1200-cu. ft. capacity, and a bilge pump of 25-cu. ft. capacity. A great number of accessories are included. Delivery is guaranteed within 210 days. The International company also sends Information Bulletin 23. It deals with the Laidlaw feather valve for air-compressors. The valve consists of three parts. Severe tests have proved its efficiency.

Mining and Scientific Press

Edited by T. A. RICKARD

Volume 110 SAN FRANCISCO, JUNE 12, 1915 Number 24

SMELTER SMOKE may not be palatable to some of our farmer friends, but it smells sweet to us, as the expression of useful metallurgical activity. With the

A SMELTER IN ARIZONA

rising price of metals we expect to see more signs of beneficent industry such as are illustrated in this picture. All the base metals have risen rapidly in market-value and the effect of it is becoming manifest in a revival of mining throughout the mineral regions of the West.

NOTES 895

A RISE 897

We yield to the wishes of our correspondents.

PROCESSES AND PUBLICITY 897

The unwisdom of exploiting technical processes in the daily press.

HOPE IN MEXICO 898

The latest move of American diplomacy has some possibility of success.

DISCUSSION

PROFESSORS OF MINING.

By *Ross E. Browne* 899

A distinguished engineer gives his views.

SPECULATION IN MINES.

By W. H. Shockley 900

Over-valuation of shares and manipulation make it dangerous for the uninitiated.

RISE OR RAISE?

By H. N. Herrick 900

Conclusion of the discussion on this word.

DREDGING COSTS.

By James Wilson Neill 901

Comparison of the Oroville and Yosemite total costs.

EXPERIMENTS IN SMELTER-FUME ABATEMENT.

By E. A. Hersam 902

The associate professor of metallurgy in the University of California advises caution.

ARTICLES

TECHNICAL REMINISCENCES—III.

By Albert R. Ledoux 903

What happened to a dredging company at Pachuca, James J. Hill's intimate knowledge of his railroad system, how Roosevelt shot a bear, serving as an involuntary guard, and how he established a reputation for insight are entertainingly related by Dr. Ledoux.

CHINA'S MINERAL EXHIBIT 906

A creditable exhibit has been made, in spite of transportation difficulties and the few companies that are in a position to participate.

GOLDFIELD REVISITED—III.

By T. A. Rickard 907

Latite, dacite, and alaskite are characteristic rocks of the district. Three main lode-channels have been found, the ore occurs in largest masses where the lode traverses dacite. The deepest shaft is down to 1772 ft. The lode finally strikes the underlying shale and conforms to it. How far it will persist in this formation can only be proved by deep exploration.

THE MOTOR-TRUCK AT TONOPAH 909

Trucks convey 5 tons per trip a half mile at a cost of 12½c. per ton. The cost of tires is 6c. per mile.

ADVANCEMENT OF MINING IN COLORADO.

By George J. Bancroft 910

Numerous discoveries in depth have recently been made. The possibility of legal conflict has been avoided by a disposition to 'get together' which argues well for the future.

HOME-MADE APPARATUS FOR CYANIDE-TESTS.

By Horace F. Lunt 911

By the exercise of ingenuity useful pieces of apparatus for laboratory tests can easily be improvised from materials everywhere available.

CORNISH MINING.

By W. J. Loring 912

Illustrations of old methods practised in Cornwall that have now been superseded. By spending 4s. more per ton of ore the total cost was decreased 11s. per ton.

THE SHUI-KOU-SHAN MINE IN HUNAN, CHINA.

By H. Y. Liang 914

The most important lead mine in China is described by its general manager. It produces almost 3000 tons of zinc ore per month, and 500 tons of galena, carrying 30 oz. silver per ton. It is entirely under Chinese direction and is worked by a combination of ancient and modern methods.

DETERMINATION OF GOLD IN BLISTER COPPER.

By Rowland King 917

Most of the copper is slagged with litharge, the rest is removed by a double scorification before cupelling. Results for silver are low, but accurate for gold.

NOVEL METHOD OF HAULING ORE CARS 917

Ingenious adaptation of a Ford motor to haul mine-cars from the mine to the mill.

EMPIRE

Let Us Give You the Benefit of Our Specialized Experience

Today we are the only concern in America giving our attention **exclusively** to the production of placer mining machinery and equipment. We have personal experience and contact with placer mining and gold dredging operations the world over. We are not manufacturers merely—we are engineers and designers, with a personal aquaintance with every phase of placer mining. We are thus able to offer to engineers and capitalists **service** unique in the mining world—a service which gives added assurance of success to your enterprise. Why not avail yourself of it.

Write for our two books on successful placer mining — the Catalogs on "**Empire**" Drills and Dredges.

"Empire" Placer Mining Equipment

includes Dredges, Drills, Hydraulic or Bucket Gravel Elevators, High-Carbon Steel Sluices and Riffles, Hydraulic Pipe Lines, Giants, etc. We design and build your equipment to suit your conditions.

NEW YORK ENGINEERING COMPANY

2 Rector Street, New York

EDITORIAL

T. A. RICKARD - - - - Editor THOMAS T. READ - Associate Editor

JOPLIN celebrated the rise in zinc to "$100 jack" by engaging a band to parade the streets. By the time the band had ceased playing, the price had risen to $106.

OUR correspondent at Houghton makes pleasant mention of the presentation to Mr. James MacNaughton from the employees of the Calumet & Hecla and its subsidiary companies. Time has justified Mr. MacNaughton's stand in 1913. He has won not only the regard of his associates in the management of these mines but the cordial respect of all the workers.

PIG-IRON output is increasing. In May the average daily production was 72,599 tons, as against 48,236 tons in December and 67,646 tons in May last. Ore shipments during May were 5,012,359 tons, as against 3,852,063 in the corresponding month of last year. There is no better barometer of industry than the iron trade, although Disraeli used to insist that the production of sulphuric acid was the best index.

AT the recent meeting of the Plymouth Consolidated Company, in London, the chairman was able to make a cheerful report concerning finances at the office and developments at the mine. Ore averaging $4.50 per ton is being worked at a cost of $3.25. The mill has proved most efficient. Local information is corroborative. We congratulate Mr. W. J. Loring, of Bewick, Moreing & Co., on the confirmation of his estimates.

ON whichever side the sympathy of Americans may be ranged in the great European struggle, they will unite in supporting the President in his effort to guide the destinies of the nation. Not without strong prejudices ourselves, we appreciate the sincerity of the President's effort to steer a true course amid the complexities of the time. The position of an idealist and a pacifist in this warring world is comparable to that of a philosopher pitchforked into a street-fight. The language he talks falls upon uncomprehending ears, and his attempts to abate the quarrel may seem to the eager onlooker so ineffective as to verge on the ridiculous. While fighting is in progress, the pacificist seems less of a man than the willing warrior, but his own people, and eventually the world at large, will recognize that there is a moral courage even higher than physical bravery. A generation hence the people of the United States, and those of Europe also, will be grateful to Mr. Woodrow Wilson for keeping his head at a time when the provocation to instant belligerent action was so obvious.

PSYCHOLOGY is a factor in mining also, says Mr. George Bancroft, who writes in this issue concerning Colorado. Thus he is in agreement with the President, who introduced the idea into a discussion of the state of general business. However that may be, we are glad to welcome Mr. Bancroft to the hospitality of our pages. No one is better informed concerning mining in Colorado, where distinct improvement has been noticeable of late.

AS USUAL we note several interesting items in the précis of technology appearing in *The Mining Magazine*. No portion of our contemporary at any time has exhibited more sincerity of purpose. Not to abstract, but to summarize intelligently, to peptonize indigestible facts with understanding comment, is a feat of journalism second to none. We tender our hearty compliments to Mr. Edward Walker, who, we happen to know, is the editor of this department of the *Magazine*.

CLASSIFICATION of the literature of applied science is to be attempted by an organization that has been formed by representatives of 20 of the leading technical societies, who met in New York recently. Mr. W. P. Cutter, librarian of the United Engineering Societies library and secretary of the new organization, known as the Joint Committee on Classification of Technical Literature, has outlined a plan for collating all the existing classifications and compiling a general system. It is expected that this will serve as a basis for the filing of clippings, for cards in a card-index, and for printed indexes; and that the publishers of technical periodicals might be induced to print against each im-

portant article the symbol of the appropriate class in this system, so that by clipping these articles, a file might be easily made which would combine in one system these clippings, together with trade catalogues, maps, drawings, blue-prints, photographs, pamphlets, and letters classified by the same system.

GOLD has been found in Northern Nigeria, heretofore associated with tin mining. But the effort to explore and develop the gold-bearing gravel, as well as the possible veins in the bedrock, of the Barco river have been hindered by departmental red tape of a most irritating kind. We sympathize with the operators in Nigeria, for the British government has not abandoned the parochial notion that mining is a disreputable adventure to which official support must not be given too hastily. As if the British empire, like the American republic, had not followed in the footsteps of the voyageur, the explorer, and the prospector. The historic fact is so plain that it needs no argument.

ZINC and its alloys are to the fore just now; so are the ores from which it is derived. It is opportune to explain why the carbonate of zinc is called 'calamine' in England and 'smithsonite' in America, these names being interchanged in labelling the silicate. At one time the oxidized ores of zinc were known as 'calamine,' which, like the *galmei* of the Germans, is a corruption from *cadmia*, itself derived from Cadmus, in recognition of its reed-like stalactitic forms. The first investigator to separate the silicate from the carbonate, and to establish the identity of the two minerals, was James Smithson, as is recorded in his paper on 'The Chemical Analyses of Some Calamines,' read on November 18, 1802, and appearing in the Philosophical Transactions of the Royal Society, London, in 1803. After this publication by Smithson, the name smithsonite was given to the silicate and that of calamine to the carbonate. Unfortunately in America the naming was reversed. It is about time for the authorities on mineralogy to come to an agreement on the matter, for the present confusion is alike absurd and unnecessary.

RUPTURE of diplomatic relations between America and Germany would have one regrettable consequence, among many: it would render impracticable a continuance of relief in Belgium, and other regions now the beneficiaries of American philanthropy. In the Belgian Relief Commission we take a special interest, for it was started and organized by a mining engineer, Mr. Herbert C. Hoover, assisted cordially by a number of other members of the profession, notably Millard K. Shaler and Edgar Rickard. Never were the initiative and intelligence developed by a successful engineering career put to more immediate public usefulness. Among many wise steps taken by Mr. Hoover, we may mention the arrangement made at the start for a monthly audit of the accounts of the Commission. This is done regularly by the leading firm of accountants in London. If other charities were conducted in a similar businesslike way they would command greater confidence. Mr. Hoover has received, and is receiving, great praise for his work in behalf of the distressed people of Belgium; we can only add our own knowledge of his untiring devotion to a noble purpose.

TWO readers of our paper have cancelled their subscriptions on account of pro-German sympathy. For personal prejudices at this time no apology is necessary. "'Tis a mad world, my masters." We are trying to conduct the MINING AND SCIENTIFIC PRESS as an American paper, which it has been for 55 years. To those who forego its use on account of political feelings, we tender our sympathy, but we suggest that it is unwise, in a moment of irritation, to cut off your nose to spite your face. One of our editors is a pro-German, as he is entitled to be from the fact that his father was a German. That fact does not cause us to depreciate his useful assistance.

ONE of our subscribers writes to inquire whether the declaring of war by Italy will have any effect on the cyanide supply, being evidently of the belief that cyanide has been forwarded to this country from Germany through Italy. It is difficult to obtain exact information in regard to cyanide, but, as nearly as we can learn, none has been forwarded to this country from Germany for some time. The plant at Perth Amboy has been enlarged and is probably able to supply the needs of consumers in the United States. The plants in England have increased their output and are supplying the South African companies and British mining companies elsewhere, but only small amounts are available for American consumers. So far as this country is concerned, therefore, that source of supply is practically negligible. The trade apparently has been readjusted along national lines, for the sellers in this country are refusing foreign orders, in order that their regular customers here may be protected. Buyers of small lots that have been in the habit of purchasing from the firm that would quote them the lowest figure will not improbably have to pay the higher prices justified by the present situation, but there seems no reason to suppose that contract customers need anticipate any difficulty.

WHILE the recent financial conference between the Secretary of the Treasury and the delegates of the Central and South American republics did not result in any definite scheme of co-operation, it was rendered memorable by a proposal made informally on the part of Mr. Bryan to several representatives of the Pan-American Union. He suggested an interchange of credit to be accomplished by the United States taking from a South American government its obligations at 4% and giving in exchange a like amount of 3% United States bonds, the difference of 1% to be devoted to the amortization of the South American securities. This has been pronounced, by good authority, both a daring and a brilliant conception. Undoubtedly if the United States

is to develop trade with her neighbors to the south she must be prepared to finance them. Trade follows credit.

ELSEWHERE in this issue we print an interesting account of the largest lead-zinc mine in China. This supplements the statement made in last week's issue by Mr. H. Y. Liang as to the opportunities for development of mining enterprises in that country. So far foreign participation in mining in China has proceeded along what appears to us the wrong lines. Efforts have been made to obtain concessions covering all the mineral rights in large areas, but such concessions have invariably proved a source of diplomatic difficulties that usually have been settled to the complete satisfaction of neither side. The normal and practicable method is the examination and exploitation of individual properties of promise, of which there are many in southwestern China. The laws of China heretofore have been unfavorable to foreign participation in mining enterprise, but a new spirit now pervades that ancient country and as a mining region of the future it is well worth attention.

DECISION by the United States District Court for New Jersey refusing the petition of the Federal Government to dissolve the United States Steel Corporation as a combination in restraint of trade has been hailed with a sense of relief by business men all over the country. Probably the ruling will not be appealed to the Supreme Court, as President Wilson is reported opposed to injecting further uncertainty into the domestic business situation by continuing the suit. At the time the hearings in this trial were being held we reported the substance of them in our correspondence columns and it is only necessary to recall how it was demonstrated that even at its inception the Steel Corporation had not a monopoly of the iron and steel business and today does a smaller proportion of the total business than it did then. As to controlling the iron ore reserves of this country, that has long since been shown to be a baseless allegation. The only point in which the Court found any ground for the complaint were the meetings of all the producers held a decade ago, but these have long since ceased. The suit against the Steel Corporation was filed in 1911, largely to meet the political exigencies of the national campaign of the following year, and it has long outlived any usefulness it may have had in that respect. In a recent issue Mr. A. F. Willoughby described the important and valuable work done by the Steel Corporation in increasing the efficiency and welfare of its employees, in which respect it has set a standard that is being followed as rapidly as practicable by other mining corporations. As we pointed out at that time, it is the large size of the Corporation that has made this development possible, while the immense benefit to the community that has accrued from it is only just beginning to be realized. It will not be surprising if the final judgment of history is that in bringing about this great advance the Steel Corporation has made a contribution to the progress of civilization far outweighing all its other activities.

A Rise

A few months ago the former editor of this paper adopted the word 'rise' as the correct spelling of the technical term 'raise,' meaning an interior opening or shaft made by mining upward. The form adopted had been used previously, notably in the McNeill code book, a volume lacking, it may be, the authority of a dictionary but representing usage among many men of business all over the world. As to the correctness of 'rise,' there is no doubt. If your salary is raised—a pleasant idea at a time like this—the result is a rise in your salary. For raising the question, we do not apologize; it resulted in a rise, from many directions. The transitive and intransitive became reversed, and the objective became overwhelmed in the subjective. However, we are not professors but professionals, using the language that is our common heritage but not posing as the final arbiters. We shall concede the point to our many friends insistent that the change is unnecessary and undesirable. In this warring world, it is not worth while to fight for a grammatical detail. Bigger issues make better game.

Processes and Publicity

In giving notoriety to new processes the utmost caution is required. An example of this is seen in the statements recently made in the press concerning the Heslewood process. For some years Messrs. James and William Heslewood, of Oakland, have been engaged in the experimental development of a process to collect the fume of smelters. The fact that the general principles involved in the process have been known for generations but have so far proved impracticable of commercial application does not necessarily condemn it, for industrial progress consists in learning how to do what no one has been able to do before. There is merely less probability that it will be possible to do something that has been tried without success, than to do something that has never been tried. The process as first devised by Messrs. Heslewood consisted essentially in enclosing the top of the furnace and furnishing the blast necessary for smelting by exhausting at the top instead of blowing in air at the bottom. Two things were to be accomplished by this: The sulphur that ordinarily burns at the top of the charge was prevented from coming into contact with the air and was thus drawn off as elemental sulphur. The gases were also drawn off under sufficient pressure so that they could be exhausted through a tank full of water, which, it was hoped, would catch and retain all the sulphur and other solids. Obvious disadvantages are involved in this procedure. To pump the gases through water requires expenditure of energy, which is the equivalent of money, and after having caught the fume in water the next question is what to do with the sludge thus produced. It cannot be discharged into the running stream, for the smelter would then escape from the farmers only to fall into the hands of the Fish Commission. The net result is the common experience of the

inventor that he solves one difficulty only to create another. In addition, the charging of a furnace with a sealed top would evidently present difficulties. Nevertheless the process presents possibilities and is worthy of experimental research.

Recently the Heslewood patents were acquired by a corporation, and one of the students in the University of California was persuaded to conduct a series of tests in the metallurgical laboratory of that institution. We have seen the report of these, indicating that the process has been modified by the use of oil and steam to reduce all the sulphur to the elemental form, but the tests throw no new light on the essential problem, namely, can the process be made to work on an operative, as contrasted to a laboratory, scale, and at a cost that is not prohibitive. Nevertheless the local press has been furnished, through the usual methods, with highly-colored accounts of the demonstration, at the University of California, of a process that is to revolutionize the smelting industry. We are glad to be able to absolve the Messrs. Heslewood, and the experimenter, from any responsibility for these statements, but it is proper to suggest that it is most undesirable that the prestige of the University should be used by a private organization for commercial purposes. Further, the exploitation of technical processes through the columns of the *Morning Howl* or the *Evening Scream* is no less out of place, and largely serves to defeat its own ends. The tired business man, who derives at least a part of his weariness from the perusal of their columns, has no interest in technical details and naturally assumes that the matter is presented to him as a piece of half-baked fiction. Whether technical processes will work or not is determined by actual experiment, opinions on the question being of interest only to those engaged in the industry and familiar with its conditions. The most brilliant investigator cannot prophesy whether a process will work on an operating scale until it has been tried on that scale. Premature and exaggerated publicity only increases the embarrassment if the experiment prove unsuccessful.

Hope in Mexico

The President has announced that

"The government of the United States must presently do what it has not hitherto done or felt at liberty to do: lend its active moral support to some man or group of men, if such may be found, who can rally the suffering people of Mexico to their support in an effort to ignore, if they cannot unite, the warring factions of the country, return to the constitution of the republic, so long in abeyance, and set up a government at Mexico City which the Great Powers of the world can recognize and deal with, a government with whom the program of the revolution will be a business and not merely a platform."

This splendid statement marks the end of the policy of "watchful waiting." It forms part of a call to the leaders of faction and misrule in Mexico "to act promptly for the relief and the redemption of their prostrate country."

Some of our readers, weary of the ineffective diplomatic correspondence and the equally futile expedition to Vera Cruz, will say that these are brave words indeed, but they have only an academic value. We believe otherwise. Before making this latest move the President was well advised concerning the condition of affairs in Mexico, more particularly the relative strength of the rival leaders, and their ability or inability to govern. His latest emissary to Mexico, Mr. Duval West, of San Antonio, unlike his predecessors in the representation of the President, speaks the language of the country to which he went to make an investigation. He was able to get first-hand information, instead of sitting in the *patio* of a hotel while an interpreter told him what his informants wished to say. In short, we believe that Mr. Wilson has finally been placed in possession of the facts. Hence his latest *pronunciamento*.

The resignation of Mr. Bryan as Secretary of State may affect the position in Mexico, by promoting a more resolute policy at Washington. On his resignation becoming known across the border, the opinion was expressed that it forecasted a firmer attitude toward Mexican affairs. That also is our opinion.

Not 1% of the population is taking part in the desultory fighting. The battles are suitable for newspaper consumption, not much more. Reports concerning the issue of these guerrilla fights are contradictory, of course, because the results are inconclusive. The latest story is that Obregon has defeated Villa and Angeles near Leon. All that can be inferred from recent information is that the Carranza or Constitutionalist group has been getting a little the best of it, and that the Villa or Convention group of *revoltosos* has lost ground. It is more nearly certain that no party shows any signs of becoming ascendant and that meanwhile the country is being beggared to the point of famine. The Chamber of Deputies in session at the capital, under the Acting President, General Garcia, has been invaded not by Zapatistas or Carranzistas but by hordes of hungry men, women, and children shouting, "We want corn." That cry, more than the grandiose announcements of 'battles' lost or won, is the keynote to the Mexican position at this time. Garcia is reported to have told the convention delegates and the mob that the treasury was empty, that the fields had been laid waste by the contending revolutionaries, and that the only hope for the people was to lay down their arms and begin the tilling of the soil.

Thus the signs multiply that the inconclusive factional warfare is about played out. If at this juncture the President can inspire some of the native leaders, such as the "neutral party" of which we hear at La Paz, to make a sincere effort to unite all of the constructive men in the distracted country, something may be done to restore tranquility, and after that political stability. The wish may be father to our thought, but we confess to more hope for Mexico than at any time during the past two years.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment

Professors of Mining

The Editor:

Sir—In the last issue of the PRESS, in discussing the proper qualifications for a professorship of mining, you express a preference for the "trained teacher of the sciences applied to mining," and indicate that the selection of practical men for the purpose has not, on the whole, proved successful. In the absence of statistical information, I assume the latter part of your statement to be well founded—in fact, it appears quite plausible. A good practical man will always serve as a good example; but take him away from his practical work, and in the absence of special qualification, he is likely to prove a poor teacher.

Still the 'trained teacher,' without practical experience is far from being an ideal professor of any branch of industrial engineering. He lacks familiarity with the conditions which dictate the character of the work to be done, and for that reason has, as a rule, poor judgment in distinguishing between essentials and non-essentials; he is likely to be wanting in a due sense of proportion. The student's time is limited, and we cannot afford to have him waste much of it.

A chair of 'Mining,' from an ideal standpoint, is difficult to fill properly. As you say, "the scope of knowledge required is staggering." In a school of mines, if we should provide two chairs, the one of 'mining engineering,' the other of 'metallurgy,' the engineering chair would doubtless be the hardest to fill satisfactorily, for the scope is the more difficult to represent in the laboratory, and the character of instruction which it is feasible to give is less easily defined. One difficulty in teaching mining is due to the student's lack of familiarity with the conditions, and this cannot well be supplied in the class-room. At Freiberg we were required to spend six months in and around the mines before entering upon the academic work. We were shifted from job to job until we acquired some practical idea of the situation. Our American schools of mines are not as a rule so situated as to make this practicable, and our mines are not under the same governmental control. At Freiberg we were further expected at intervals during the periods of instruction to do special practical work at the mines and metallurgical establishments. After leaving the Academy, I was able to undertake either surveying or assaying, but in other respects I found myself ignorant of all useful work around the mines. Thus the Freiberg course was rather ideal in some respects, but far from perfect in others. As I now look back, the course in mining proper seems to have been very poor. In fact, while there are excellent courses in chemistry, mineralogy, geology, metallurgy, civil and mechanical engineering, I do not know of any college course in mining proper that amounts to much. There may be such, but I am not familiar with it.

The student should graduate with a good foundation in chemistry, mineralogy, geology, metallurgy (in a general way), and in the elements of civil and mechanical engineering, and for practical purpose he should have a fair facility in surveying and assaying. Without detriment to his work in these subjects, the professor of mining, no matter how well qualified, can do little more than give an outline of the main branches of engineering involved in mining, such as excavating, hoisting, pumping, timbering, etc.; for there is not time enough in the ordinary undergraduate course, and the student's mental digestion is already overtaxed. Lectures by experts may be well enough as matters of diversion, or as incentives to the more ambitious, but the average student will not be qualified to profit by them.

So far as my experience has taught me, I should rather see the graduate well founded in the fundamental engineering and chemical branches without much knowledge of practical mining, than to see the greater stress laid on the latter subject. The present undergraduate course in our university does not permit of much more than this in any event. Very few of our successful mining engineers knew much of actual mining before entering the field. The best service the professor in charge can render is to insist upon the fundamental work being thoroughly done. If post-graduate work were feasible on any considerable scale, which is doubted at the present time, a different view of such work might be taken.

As the matter now stands, it seems to me the professor of mining should be qualified by education and experience, not so much to give special instruction in mining proper, as to see that the students under his charge may get suitable instruction in the fundamental subjects; that their work may be so planned as to be specially thorough in the directions in which it is most likely to be useful in the future. This requires knowledge both practical and theoretical. The professor of an engineering college should be mature enough to have a practical grasp of his subject, and young enough to possess an enthusiastic desire to make his course a success. He should be, say, preferably between the ages of 35 and 45 years when selected. In a general way, it will be conceded that the personality of the teacher is always of special importance. He should

have the faculty of inciting both interest and effort.

The question arises, where are such men to be had? There are doubtless many such, the trouble is that they are likely to be ambitious in a practical way, and will not be attracted by the salary of a professor. The work will probably appeal more to those among the qualified who already have adequate means of living.

In conclusion, I must say I thoroughly agree with you in laying special stress upon the importance of the "sciences applied to mining," but I should not be satisfied with a trained teacher without practical experience.

Ross E. Browne.

Berkeley, June 1.

Speculation in Mines

The Editor:

Sir—In this letter I confine myself to precious-metal mines whose shares are listed on some stock exchange. My advice to people who have never speculated is identical with *Punch's* advice to those contemplating matrimony: Don't. And this same advice is given by most mining engineers of my acquaintance, including some who have made large fortunes by legitimate—and illegitimate—deals. The reason they thus advise is that not one man, or woman, in a hundred who speculates in mining shares ever makes a permanent profit; the shares are invariably quoted at least two or three times their intrinsic value, and hence, taking the whole list, there must be a loss to the speculators of fully 50% of all the money they put in.

The question naturally arises: if there is such a certainty of loss in the aggregate, why do people buy the shares? I answer this question by asking another: Why do people buy lottery tickets although the sale of them is illegal and there is an absolute certainty of loss for the whole group of buyers? Infants in arms know that the answer is that each individual buyer of a lottery ticket thinks he may win the big prize and every buyer of a mining share hopes for a Mohawk—where a 20c. share went to $20 within a year.

In addition to the over-valuation of shares, the buyer is confronted with market manipulation. Take the case cited by Dr. Ledoux, in your issue of May 15, where Rothschild paid his fee by purchasing Rio Tinto shares and selling them at a profit: Rothschild certainly had inside information and probably bought the shares for less than they were worth and sold them for more; that is, he acted on information not available to the ordinary shareholder. Sometimes this manipulation is carried much further; for example, a mine is paying a fair monthly profit, if the outlook for the future is good the dishonest management will probably work the lower-grade ore, do much dead work, lay in large stocks of supplies, and give unfavorable tips to the brokers, meanwhile selling blocks of shares. As a result of all this, down go the shares and the insiders load up. When the proper time comes the joyful news goes forth that the shares are marked for a rise, rich ore is worked, as few supplies as possible are bought, dead work is stopped, great profits are made, and the shares are valued on the basis of long-continued profits at the abnormally stimulated rate, and after a few months down go the shares again, *et cetera*.

Perhaps it is as well to state clearly that such manipulation of shares is not universal, nor does it follow that marked variation in the price of shares is evidence of manipulation. Often the public makes the price; I happen to know of a mine which was without any ore of consequence but had prospective value because it adjoined a mine that was in bonanza. The management of the bonanza mine withheld all information as to the position of the orebodies and after much blind prospecting the less fortunate owners decided to shut-down and wait developments. The surveyor of this mine, knowing that it was about to close, sold his shares at 40c. The next day the shares were 80c. and remained there for a long time. Some wise brokers decided that rich ore had been discovered and that the mine was shut-down so that the owners could buy the outstanding stock at a lower figure.

What is needed to stimulate interest in mining speculation is the discovery of another Cripple Creek, Goldfield, or Tonopah. In default of such discovery an annual official report by the Bureau of Mines on all mines that are listed in stock exchanges, with a valuation of the shares and discussion of future prospects, might lead to a healthy speculation and to investment of funds by those who now feel that while there are plenty of honestly managed mines there are also others whose dark ways are full of vain tricks.

W. H. Shockley.

Palo Alto, May 22.

Rise or Raise?

The Editor:

Sir—I would suggest that the question lately raised or risen in your discussion department with respect to the use of the word 'rise' is one of fact, and therefore capable of exact determination.

The problem may be stated thus:

Is the type of mine working under discussion ordinarily called a 'rise' by "authoritative writers" or is it not?

To determine the answer to this problem and to justify its position beyond possibility of further question, the editorial staff of your paper has simply to prepare a list, as complete as convenient, of examples of usage from technical literature, somewhat as follows:

Johnson, 'Theory and Practice of Surveying,' p. 399, uses upraise.

'Handbook of Mining Details,' p. 106, uses raise.

Storms, 'Methods of Mine-Timbering,' p. 40, uses raise.

International Text-Book Co.'s books use raise.

'Coal and Metal Miners Pocket Book,' p. 619, uses upraise—defines "rise workings" as generally descriptive of all workings "to the rise of" (that is, higher in the bed than) the shaft-station in coal mines, p. 606. A few

scattering papers in Trans A I M E use raise No complete search.

Technical periodical literature, including some articles in the *Mining and Scientific Press*, uses raise

The Encyclopedia Britannica, 11th Ed., Vol. XVII, p. 531, Fig 6, illustrates and describes such a working as a 'raise.'

The "vulgarisms of the careless educated or reckless illiterate" cited above are the result of a hasty survey of a meagre library, and given only as a suggestion as to method of attack. It was my intention to furnish a parallel column showing examples of the use of 'rise,' but as the resources at command unfortunately fail to show any such, I leave the task to abler hands.

Whatever the decision as to the name, I must confess to certain doubts of the propriety of describing the driving of a 'rise' as 'rising.' The verb 'to rise' connotes a certain spontaneity on the part of the thing rising, whereas painful memories of former experiences suggest that a 'rise' or 'raise' has to be raised.

H. N. Herrick.

Berkeley, Cal., May 12.

[Publications giving reliable information are not necessarily authorities on the use of words; the decision in such matters can be claimed only on behalf of those who show a special interest in the matter. We shall not discuss the question further, having decided to yield to the wishes, not the arguments, of our friends, as is explained in the editorial columns.—Editor.]

Dredging Costs

The Editor:

Sir—In the issue of your paper of February 13, 1915, an incomplete table of costs of dredging by the Oroville Dredging, Ltd., was published; in attempting to compare these costs with those of our company, I was unable to check the figures and finally had recourse to the annual statement of the Oroville company. As others may be in the same condition that I was, I beg leave to give the needed data, to complete the calculations.

Three boats were in operation during that year, but of these, one, the Exploration No. 2, was laid up and dismantled during the year, only working 5.66 months, thus we had a total of 29.66 months working-time on which to figure the yardage; namely 97,693 yd. per month.

The dredges Boston No. 4 and Exploration No. 4 are 7.5-cu. ft. boats, the Exploration No. 2 was a 5-cu. ft. boat. They are digging on the north side of the river, in stiff ground, and the record is no doubt a good one. The "costs" as given in the table are of course not the cost of the operation to the stockholders, but the cost of the work at Oroville, or strictly 'operating cost.' To them should be added the overhead charges, office salaries, etc., etc., to get the actual cost. These are given in the report, and bring the total up to 4.64c. per yard. This is after leaving out items amounting to $8645.45 for machine-shop losses and administration expenses, which, if added, bring the actual cost *to the stockholder* up to 4.94c. per yard.

An accurate comparison of these figures with those of our dredge is not possible owing to the different method of charging the materials. The Oroville statement calls for "labor and material"; we separate them into 'labor' and 'repairs and supplies,' charging into this latter account all materials whatever, labor covering the pay-rolls only, salaries being charged to 'general expenses.'

General expenses with us also covers all items such as bullion expenses, taxes, legal, automobile, and so forth.

Our dredge is a 3.75-cu. ft. boat, digging in 15-ft. ground, clean river wash; the record given is for the last two years of the life of this boat, being the end of a campaign of six years.

Oroville

Time covered by record	29.66 months
Total yards dug	2,897,557
Yards per month	97,693 per boat
Average depth	30.5 ft.
Average running time	20.38 hr. per day
Average running time	84.9%
Costs, material and labor	1.25c.
Electric power	0.75
Water	0.08
Repairs	1.06
Smelting and express	0.03
Taxes and insurance	0.21
General expense	0.66
	4.04c.
Add other costs as above	0.90
Total cost	4.94c.

Yosemite

Time covered by record	24 months
Total yards dug	2,079,717
Yards per month	86,655 per boat
Average depth	15.0 ft.
Average running time	20.90 hr. per day
Average running time	87.1%
Labor	1.256c.
Electric power	0.843
Clearing land and water	0.100
Repairs and supplies	1.02
General expense	1.12
Total cost	4.339c.

These costs are now comparable, being the actual cost to stockholders.

Conditions on the boats are in many respects similar, as in each case they are approaching the time when they would be dismantled; therefore the purchases for repairs and renewals would be kept down to a minimum; that this is the case is shown in the Oroville report, where the up-keep on Exploration No. 2 is much less than on the other boats; on our dredge the repairs were maintained on such material as we would move to a new hull, on others just enough was done to maintain efficiency, and that this efficiency *was* maintained the record of 86,665 yards per month for a 3.75-bucket boat speaks clearly. Of course, this condition only obtains during the last few months of the campaign!

The Oroville report gives some figures of general interest to the dredge-man, in the stated life of the wooden hulls on these boats, to wit, Exploration No. 2, nine years,

worn out and dismantled; Boston No. 4, built in May 1906, therefore now nine years old and digging; Exploration No. 3, built in October 1906, now eight years and seven months, and still digging. It would be interesting to have the data as to what, if any, preservatives were used on the timbers, and what, if any, methods of ventilating the compartments of these hulls were provided in their construction.

JAMES WILSON NEILL.

Snelling, California, May 19.

Experiments in Smelter-Fume Abatement

The Editor:

Sir—A recent outburst of newspaper appreciation has brought again the smelter-fume problem to the popular attention. For those who may forget that serious discovery seldom takes this form of first presentation it is not amiss to say that science has no startling discovery in the field of sulphur-fume abatement to lay before the public at the present time. For many years thoughtful and costly experiments have been conducted in different states and different countries to throw light on this general subject, and the work is still going on. The search for underlying principles, and the investigations to test the applicability of these, to efficient practice, are the successive steps by which progress is made. We must hail every earnest contribution and recognize its merit. Not less important is it to clear the field of the unproved notions that make advancement so devious.

At the University of California we are receiving inquiries as to the results of the operation of a certain experimental smelting-furnace in the laboratories of the Hearst Mining Building. The newspaper references to sundry simple facts may create an impression that the experiments, conducted there, will hardly justify. So many of the so-thought impossibilities of the past have been made the achievements of the present, there is little wonder that people have to be reminded, from time to time, of the sharp distinction there really is between hoped-for discovery and proved fact.

In the smelting industry there are no wants felt more keenly than those of a way to further employ oil-fuel, of a way to reclaim sulphur from sulphide ores, and of a way to obviate the production of sulphur fumes. The accomplishment of all these desired ends by one decisive invention is more than we would ask, and, I believe, is more than anybody will claim. We must look skeptically upon all innovations that run counter to accepted principles, and must question all claims as to new processes, on this order, that are unaccompanied with most convincing proof.

Every metallurgist knows that smelting under a reduced pressure in the blast-furnace, with suction rather than with a blast, will be always subject to a handicap. It is not an effort to be thought of, unless compensating gain is to be derived from some unexpected quarter. Every metallurgist knows that the use of oil or of gas, as fuel for smelting ore, in any sort of a shaft-furnace, will be attended with most serious mechanical difficulties. No possibility in metallurgy has been, perhaps, more fully investigated.

Nothing would be more pleasing, in our domestic industry, than to turn our offensive sulphur gases into a useful sulphur by-product. We know that this may be done someday, just as we knew that someday men could fly, like birds; but we need more knowledge of temperatures, of reactions, and of principles. And after further knowledge of these essentials is had, there will still be much to be done in adapting theoretical principles to profitable practice. We are not justified in applying our conclusions, obtained from small furnaces, to large-scale operation, except by careful degrees and by knowledge in great detail.

At the University of California, one of the students, A. B. Marquand, has recently studied some of the conditions in smelting sulphide ore, with a view to collecting the escaping sulphur, and on a scale somewhat larger than is commonly possible in research laboratories. In his work, Mr. Marquand has been aided by James Heslewood, and his son William, without whose assistance the work could not have been performed on the scale he desired.

The work led to a study of the action of steam and of oil in the roasting and smelting of sulphide ores. The recovery of a large part of the expelled sulphur, in the form of a sulphur product of a purity sufficient to justify its refining and utilization was a notable step in the direction of present-day needs. We shall look, in due time, for a publication by Mr. Marquand of some of his results. We desire, however, much more than has yet been accomplished, or than Mr. Marquand would thus far be able to publish.

Before we can accept the work, for adoption into large-scale practice, we shall ask for proof that he can utilize his fuel efficiently, that he can adapt his furnace to a scale that will admit of a practical output, that he can recover his sulphur with sufficient economy. It is something to have demonstrated what his furnace has actually shown. The difficulty will come in securing economy of operation.

E. A. HERSAM.

Berkeley, June 1.

LATERITE is essentially a mixture of ferric hydroxide, aluminum hydroxide, and free silica in varying proportions. Laterites differ from true clays in the absence of the aluminum silicate, kaolin, and the presence in its place of some aluminum hydrate. Laterites develop only in tropical and semi-tropical regions of heavy rainfall and only from basic rocks. The wide extent and great depth of lateritic deposits make their consideration of prime importance in the study of iron-rich residual deposits. Moreover, laterites represent a more complete decay of rocks and a greater removal of silica, than do ordinary clays. Therefore they must show a proportionate increase in the remaining constituents, and consequently, other factors remaining constant, a residual deposit richer in iron.

Technical Reminiscences—III

By ALBERT R. LEDOUX

One of the first and most important investigations which I was called upon to make was in 1883 in Mexico. An American company had acquired from the city of Pachuca the right to dredge the river running through the town; in fact it had obligated itself to dredge it to bedrock and keep it at a certain level, the only remuneration being that it should have the benefit of any valuable metal recovered in the operation. An English engineer by the name of Brown had brought alleged samples of the river-bed, which showed considerable value in silver and mercury. As is well known, the great *haciendas*, or reduction works, of the district are situated above the town on this stream. The tailing from their *patios* was washed into the stream until it had gradually filled, according to the engineer's report. Retaining-walls or levees had been built higher and higher on each side to prevent the water from overflowing the town. Without any further investigation, the Americans accepted Mr. Brown's report, entered into a contract and erected a plant to treat this tailing and save the amalgam and other metals. They proposed to dredge or pump the tailing from the stream, sluice it into their plant on the river-bank, and recover the metals by concentration. Someone had made tests and had recommended certain machines, and the experiments made on some tons of the material indicated a profit.

I was sent down to be present when the works were started and to report on the process, and incidentally because there seemed to be some friction between the heads of the local management. I was given a power of attorney with full authority over everybody. Upon my arrival, I quickly discovered that the friction arose because there were three heads to the enterprise: a Cornishman, an American, and an Irishman. One had entire charge of the expenditure of the funds; another had charge of the mill; while a third had control of the operations on the river. They were not on speaking terms, and the first thing I did was to call them into a room and say that I proposed to make one of them supreme; that I had made up my mind who it should be, but I wanted them all to agree in advance that they would accept orders from and work loyally under the man that I should select as head. Two of them agreed to this, while the third refused and handed in his resignation.

I might say here that I had planned to leave Pachuca on a certain day for El Chico to look at a mine there—a few hours over the range on horseback—but received a request to call on the *jefe politico*. This official asked me if I intended to go to El Chico. Upon being informed that such was the case, he advised me not to go, saying that some peons who were spending money freely in a saloon had told in the hearing of an agent of the police that they had been paid partly in advance to assassinate an American on a lonely trail to El Chico on a certain day. The *jefe politico* said he supposed I knew who had hired these peons, "a man I had put out of his job," and offered to give me a written permit to shoot him at sight! I found that my desire to visit El Chico had grown considerably less; nor did I wish to shoot the man indicated. I followed the custom of that day in carrying a 'gun,' which was a long Colt suspended from the hip on a belt-swivel. At the noon-hour next day, I showed some of the men working on the plant that I could make a fairly good shot from the hip, and asked them all to let me know where I could find the gentleman, as I understood he had hired men to assassinate me, and that I had authority to kill him on sight. A day or two afterward, the chief of police informed me that my friend had suddenly left town, going across the range to Tuxpan, whence he expected to sail. This man had the nerve to call at my office some six months afterward on the excuse that he wished to have an assay of a sample of ore. I told him that I still had a permit to shoot him at sight, and, although it might not be valid in New York, I was inclined to see, and made a reach for a drawer in which at that time I kept a pistol. He did not stand upon the order of his departure, and I have not heard of him since.

My visit to Pachuca was just before the rainy season began. The river-bed was dry except for a little trickling stream, and was lined with men and women making good wages by washing the sand for amalgam and concentrate. I had some misgivings as to the depth of the deposit, or as to whether the yield below would be found equal to the surface indications, so ordered a shaft to be sunk to bedrock. I found that the tailing which was the source of the revenue of the peons was only a foot or two deep. Below there was practically nothing but boulders, with occasional pockets of valuable sand, and I quickly saw that the company could not by any possibility make money under its contract to dredge the river to bedrock. I had noticed that while the peons were washing the gravel and some were working in the shaft, one of their number sat on the wall facing up stream. Suddenly about noon, he gave a peculiar cry. The men came scrambling up the ladder and joined him on the wall; the women fled from their diggings. In a minute, there came roaring down the cañon a flood of water several feet high, carrying boulders of considerable size, which made a horrible grinding sound as they passed. There had been a cloud-burst in the mountains, and after it passed, the sand and tailing had been absolutely washed away, leaving nothing but the formerly or recently deposited boulders to be seen. The peons, who had all fled to a place of safety, mourned that their occupation was gone until the end of the rainy season, when there would gradually be formed a new layer of tailing which it would pay to wash.

One of my most interesting mining trips was made at the request of Mr. James J. Hill, of the Great Northern Railroad, at the time when the line of the extension from Havre, then known as Fort Assiniboine, to the Pacific Coast was being located by his engineers. It was my duty to report upon the indications of mineral as a possible source of revenue from points relatively accessible to the road. Part of the time I was the guest of Mr. Hill in his car, and we drove into the Sweet Grass Hills region from Fort Assiniboine, some 80 miles, sleeping at an isolated ranch-house or improvised shelter. Somebody had been prospecting near the summit of one of the three peaks of the Sweet Grass Hills, and had found iron ore that yielded copper to assay at a depth of about 100 feet. Several had located on the outcrop, which seemed to be a vein rather than a bed, but they had been puzzled by the fact that the vein continually crossed their side-lines on the strike. I found it to be what might be called a picture formation, differing from anything I had seen before, or have seen since. The igneous rock, which I probably called 'porphyry' in those days, formed the body of the mountain. Near the top it had shoved its way through some old limestone bed, tilting the latter until it stood at a sharp angle, and changing it into as beautiful, white, finely crystallized marble as I have ever seen. This marble appeared to the eye quite like that of Carrara. It formed a ring or collar almost all the way around the top of the peak, and the copper formation had been deposited at the contact between the porphyry and the marble. There was considerable iron —enough to justify exploration some day—and some pockets of rich sulphides, although the average of copper at the bottom of the workings then exposed was very low.

I have only seen one other deposit at all similar: a bowl of marble lying on top of granite on the Mississippi river of Canada. Between the marble and the underlying granite was a limited deposit of chalcopyrite, neither extending into the granite nor into the marble.

Returning to the railroad near the vicinity of Fort Assiniboine at 2 a.m., down the grade from the direction of Benton came a freight-train, with two hot boxes blazing. The train stopped and the crew got busy with water-buckets, when Mr. Hill drove out of the darkness and called out: "What is the number of this train?" Someone answered (let us say) "No. 24." Mr. Hill, who in those days knew almost every man in his employ, called out: "I believe (let us say) Morris is the conductor of 24: Is he there?" A gruff voice answered, "Yes, I am here; who are you and what do you want?" Mr. Hill said, "I am curious to know whether there are any rules as to the speed of freight-trains on this line." The man replied, "I don't know what business it is of yours, but we are supposed to run 20 miles an hour if we have live-stock, and 12 otherwise." Mr. Hill said, "24 does not carry live-stock, does it?" The man replied, "No." Mr. Hill said, "One more question: How fast were you coming down that grade?" The man replied, "It is none of your damn business; who are you, anyway? But I do not mind saying that we were running 25 miles an hour." Mr. Hill said, "Morris, you were running 35 miles down that grade, which accounts for your hot boxes. You have shown that you know the rules of the road; take this train into Chinook and turn it over to so and so, and consider yourself discharged. I am Mr. Hill, the president of the road." Morris came forward with his mouth open and thrust a lantern into the buggy, with the exclamation, "My God, it's the old man!"

I could go on but for my limit, telling similar experiences, showing Mr. Hill's wonderful knowledge of all detail in connection with the railroad of which he was then president. One day we were side-tracked at a water-tank. The engine of a freight stopped near our car. Mr. Hill said: "Hello, that engine is No. 44. Let me see—I believe Jim Smith is the engineer." We got out of the car and Mr. Hill walked over to the engineer, who was oiling up, and said, "Hello, Jim. How is 44 working now? You had her in the shops week before last; I think it was to have a cylinder bored out, wasn't it? Is she all right now?" The man was perfectly astonished and evidently delighted, and afterward said to me: "What do you think of that? I was for ten years on the Blank railroad before I came to the Great Northern. Most of the time I did not know who was president, and I am sure that the president did not know of my existence; but here on the Great Northern, the old man not only knows my name, but has kept watch of old 44, and appreciates it if I treat her well. That's the kind of a man to work for!"

After leaving the railroad on that trip, I was sent into Kootenay Lake district to report on the resources of that region, including the old Blue Bell mine, which had been worked since the early days of the Hudson's Bay Company, and as to the prospects of the then recently discovered camps of Warm Springs, Sandon, and Kaslo. I had an adventure at Warm Springs, now known as Ainsworth, which was as exciting as any that I have experienced.

I had crossed the lake from the Blue Bell with the late Andrew B. Hendryx. A gale had sprung up making it impossible to return by row-boat, and we were obliged to spend the night in the camp. There was no such thing as a hotel, the town consisting of a few houses, several saloons, and a general store. The proprietor of the store offered us blankets and said that we could sleep on the floor. The clerk closed-up after we had lain down, carefully bolted the door, and retired to a little room that opened into the main store. Hendryx and I lay side by side. I had taken my pistol from my hip pocket and put it near my head—not because I expected to need it, but because it was uncomfortable to lie upon. I was awakened after midnight by a light shining in my eyes, and without raising my head, I saw a trap-door at our feet slowly rising, a hand holding a lantern, and a pair of shifty eyes staring at us. I made up my mind that someone intended to rob the store, but thought that he would desist upon seeing that it was occupied. Not so; the man turned the trap-door back carefully, motioned to another, and both came up. Be-

tween them they had a bag. Hiding the lantern beneath their coats, they tiptoed from shelf to shelf, selecting articles which they put into the bag, occasionally glancing in our direction. I had the uncomfortable feeling that it was my duty as a guest of the proprietor to prevent this robbery, but determined to wait until the men had started down the trap-door, when I could cover them easily and hold them while I called the clerk; and then occurred the most unexpected thing that could possibly be imagined. After they had filled their bag, instead of seeking exit the way they entered, or even going out the front door they went to the door of the room where the clerk was sleeping and kicked violently upon it. Hendryx sat bolt upright, as did I. I grasped my gun and awaited developments. The clerk came out and talked to the men and then let them out of the front door and locked it. In my agitation I said, "Do you know that these men have been robbing your store?" "Oh, no," he said, "they are a couple of boys from the Sky Line mine; they are all right. The boss sent them down with some money after a bill of goods. They gambled the money away tonight at a saloon, knew that my boss would not give them credit; that they must be back to work early in the morning; remembered that the trap-door was not usually locked, and so came in and helped themselves to the stock and have given me a memorandum of it. They are all right and will pay me on the first of the month."

I yield to the temptation to tell an interesting story which was told to me on that trip by a trapper, to whom I had given shelter at my camp-fire on Kootenay lake. He said that he had just been up in the Selkirks guiding a man named Roosevelt, who wanted to get a cinnamon or silver-tip grizzly—I had forgotten which—that they had gotten one and that he had just said goodbye to his employer, then Police Commissioner in New York, and was on his way back, but was storm-bound on the lake. He said: "That man Roosevelt is the bravest man I ever saw. He is very near-sighted and has a pocketful of different kinds of glasses. We were going up a narrow trail in the grizzly country, when I saw around the turn not very far ahead, a big bear shambling down. I dropped back and motioned to Roosevelt to look around the corner. He stepped slightly forward and saw the bear not over a couple of hundred feet away. The trail was narrow, on one side a cliff, on the other a ravine. Instead of putting up his gun immediately and shooting, Roosevelt groped around in his pocket until he found the pair of glasses that he wanted, unhurriedly removed the pair he wore, rubbed, put on and adjusted the others, and when the bear got within 50 feet of him, took deliberate aim and killed him." In picturesque language, the old guide said that any son of a gun who would take the time to change his glasses when a grizzly was loping down the trail within a few yards of him, was the bravest man he had ever seen.

I came out to the railroad from Kootenay in a light twin-screw steamboat, which tied up for the night at the Canadian custom-house north of Bonner's Ferry. The house was attractive, surrounded by a flower-garden. The Canadian customs official met the boat, accompanied by a pair of greyhounds and a charming wife. I suppose I should have mentioned the lady first. I had expected to occupy a corner of the cabin with my sleeping bag, but Mr. Dash most cordially invited me to be his guest for the night. They gave me a charming supper, and the lady, about ten o'clock, said that if I wished to retire, she would show me to their guest-room. I caught a queer expression on the face of my host; his wife, however, did not seem to notice it. I said that I was quite ready to retire, but that if it were in any way inconvenient, I could spend the night quite comfortably on the boat. When she protested that they had a spare room entirely at my disposal, I saw my host reach under the table with his foot, endeavoring to attract his wife's attention. He said, "I have made arrangements for Mr Ledoux to sleep in the office. There is a comfortable bed there, and he perhaps will feel more free to get up when he chooses—especially if the boat leaves early." I saw a puzzled expression on his wife's face but I chimed in with my host's idea and was escorted to the office. It contained a safe, a desk, and a sofa with blankets. When my host bade me good-night, he called my attention to a Winchester, leaning against the wall at the head of the sofa. I was soon asleep, but was awakened by a noise. It was a moonlight night and I distinctly saw the shadows of two men working at a window. I could hear them whispering, and then they tried the door. I called out to know who was there and heard retreating footsteps. The next morning, my host asked me if I had slept well. I told him 'Yes' but for this interruption. He then said I had done him a good turn by sleeping in his office; that they had been repeatedly robbed of money accumulated from customs receipts; that their opportunities for sending cash out of the country were infrequent; that he had $2000 in the safe that night and thought possibly some of the rough characters who had come up on the boat might try to break in, and that if they found the office occupied, they would go away, as indeed they did.

And now I must tell how I established my reputation in Colorado. I was under contract to examine a property in the San Juan, and received instructions when I arrived at Denver. The vendor's statement of earnings, and conditions at the mine and mill, made it seem to me that the price asked was extraordinarily low. The time under the option was drawing to a close, and my instructions were to examine the mine and telegraph my Eastern clients whether they should buy it or not. I sought to ascertain the reasons for selling, and was given the usual story of a quarrel between partners, or of the death of a partner—I have forgotten which. Proceeding to the mine, I found it had one of the typical fissure-veins of the region, strong, well-defined, and persistent. The mill-returns showed an excellent profit and the conditions of mining were satisfactory. Work was going on at several levels, but there was an adit at the bottom of the mountain that should have cut the vein a few hundred feet below the lowest working. The people interested tried to keep me out of the 'tunnel', on the ground

that it was caved and dangerous. However, I persisted and soon found what I took to be the reason for the willingness of the owners to sell. They had not caught the vein in this adit; nor had several cross-cuts encountered it. From the angles that I had taken above, I knew the vein should have crossed that adit, unless there was a change in the dip, of which there was no suggestion above; there was no indication of a fault observable. As I came out of this adit in the afternoon, I had a sort of 'hunch' that the dip might have become more flat, and if so, the vein would not be very far from the adit, but on the other side from the cross-cuts. I said to the shift-boss who was guiding me, if that were my mine, I should look "somewhere over there for that vein"—making a sweep with my hand in a general direction.

I determined to wait until morning before telegraphing my people to turn down the option, in view of the showing, and to go through once more. This time, even more strenuous objections were made to my entering the abandoned 'tunnel.' They said that I had seen it already and that there was nothing there. However, I again persisted, and shortly came upon indications of freshly broken rock, which had been piled up in the aperture that had been made. The foreman tried to make me believe that it was in that condition when I visited the mine the day before, but I knew better, and ordered some miners to be brought to tear down the wall. Much to my surprise, when the opening was made, I found that the vein had been encountered and cut through for some three or four feet within a yard or two of the adit. The ore looked as good as anywhere in the mine. I advised my clients to take up the option and found that I had made a great local reputation which, indeed, preceded me to Denver. I do not know how many people told me that the foreman had said that he would give anything to have the knowledge of that tenderfoot from New York, vowing that when I was in the adit the first time, I had pointed to a particular piece of rock that stuck out of the wall, and had said to him that "the vein is in *there*, Jim, not more than a yard;" that he had put a shift at work as soon as I had gone out, and they had found the vein. They had filled up the working in the hopes that I would not see it, for now nobody wanted to sell at the price of the option. It took several visits to Colorado before I could live down the reputation I had gained of being able to see through the country-rock. I actually had to refuse a half interest in one prospect, tendered in the confident belief that I was a clairvoyant.

A SERIES of laterites from India run 13.75, 23.41, 26.61, 34.37, 37.88, 47.27, 51.25, and 56.01% Fe_2O_3. The parent rock is not given. Two laterites from Surinam contain 55.94 and 62.08% ferric oxide. Merrill cites an Indian laterite with 55.5% Fe_2O_3. The parent rock is not given. Culver cites certain unpublished data furnished by W. J. Mead, of the University of Wisconsin, on the lateritic iron ores of Cuba. The original is a serpentine rock, the freshest of which contains 9.8% Fe_2O_3. Their formation from basic rocks is one reason for their high iron content.

China's Mineral Exhibit

The exhibit of China's mineral resources at the Panama-Pacific Exposition is very creditable, when it is remembered that the mining industry is as yet in the first stages of development. Most of the exhibits have been sent by the four or five companies that are exploiting mines on a large scale. The central feature is a large relief model, about 20 ft. square, of the surface plant of the Shui-kou-shan lead mine in Hunan. This is supplemented by topographic and geologic maps, sections of the underground workings and specimens serving to convey a clear idea of the most important metal mine in China, which, though only worked by modern methods for a few years, is producing 3000 tons of lead and zinc ore per month.

Next is the exhibit of the Han-Yeh-Ping Coal & Iron Co., showing sections of rails, I-beams and angles, track-bolts, and other railroad accessories, samples of the various grades of coal mined, and the excellent coke made from it, and also blocks of the iron ore. Numerous photographs show the equipment and methods of working of this interesting property, which was described in some detail in the MINING AND SCIENTIFIC PRESS of October 29, 1910. On the opposite side is the exhibit of the Kailan Mining Administration, into which the Chinese Engineering & Mining Corporation has now been merged. Photographs, samples of coal and coke, and of the various fireclay products made by this large and prosperous company are supplemented by a well-printed booklet distributed by the company. Near-by is the exhibit of the Chee Hsin Cement Co., a formerly affiliated and adjacent enterprise; as cement does not lend itself to display, the company has wisely featured the great variety of tiles for flooring that it produces. In a central glass case are two unusually fine nuggets of gold from northern Manchuria; leaning against the wall beyond are slabs of polished marble that are not likely long to hold the visitor's eye, but which nevertheless indicate the beginnings of profitable industry, for China is a densely populated country, and the materials of construction are likely to be a source of much profit if wisely exploited. The Kwang Tung Cement Works of Canton, started in 1906, exhibits several ornamental casks of cement, of which it produces 200,000 barrels per year. One of the most interesting features, and one likely to be overlooked, is a collection of 15 framed photographs of the property and equipment of the Pai-shui-ho Copper Mining Co. at Feng-hsien in Ssu-chuan. Small blast and reverberatory furnaces are shown, the making of copper from matte by the Japanese *mabuki* method, and the generating of power for the enterprise by large water-wheels, made of bamboo, and much resembling the tailing-wheel at the Calumet & Hecla mill. In various cases there are numerous specimens of the 300 useful minerals that are found in China. Single specimens are not usually of much interest, but in this case they serve to verify the truism that China is a country of great mineral resources.

Goldfield Re-visited—III

By T. A. RICKARD

Geological Notes—Postscript on Milling

In 1908 it was recognized that the big orebodies were in veins traversing dacite, or quartz andesite, which owes its porphyritic habit to phenocrysts of feldspar. The feldspar is labradorite, characterized in this district by alteration to alunite, forming a white clay, which is a factor both in the mining and the milling of the ore. Fortunately (thanks to the vacuum-filter) it has not hindered the milling as much as was at one time anticipated. The thickness of the dacite had not been determined in 1908. Beyond the central area it was known to be covered by andesite and on the bottom (380-ft.) level of the Combination mine, an appearance of andesite dipping 34° northeast had suggested an important change of rock in depth. At that time it was recognized that the lode-channel follows lines of silicification and alunitization. It seemed to me then that any confident expectation of continued persistence of rich ore in depth was not justified by the geologic structure of the district. The "andesite" uncovered under the dacite in the Combination workings is the rock now called 'latite.' This term was originated by F. L. Ransome; the word is derived from Latium, an Italian province; it is applied to effusive rocks intermediate between trachyte and andesite. As employed at Goldfield it represents the "earlier andesite" of the first report published by the Geological Survey. Dacite stands for the quartz-andesite group. It is named after the Roman gold-mining province of Dacia, now Transylvania. It is difficult to distinguish latite from dacite, especially where the rock is altered near lines of mineralization. Latite can be distinguished best by the streakiness of its groundmass, a distinction not available to the miner underground. The dacite is supposed to be intrusive into the latite, the upper portion of which has been eroded. In depth, the workings of the central area, largely identified with the Goldfield Consolidated property, follow the lode first through the dacite, then through the latite, and finally into alaskite and shale. Alaskite is another recent petrographic term. It was proposed by J. E. Spurr in 1900 to cover rocks consisting essentially of quartz and alkali feldspar, without regard to texture. Formerly the term 'aplite' would include such a rock. When I asked a superintendent what 'alaskite' was, he was at a loss to give a definition, so that when I suggested "a sort of bastard granite," he assented hastily. According to Spurr, it represents the last phase of magmatic differentiation. In the Jumbo Extension, at the 1017-ft. station, I saw a vein of alaskite zig-zagging through the shale. It is clearly intrusive into this underlying sedimentary formation, which ranges from a black shale to a 'short' limestone. Previously it was known from exposures on Columbia mountain, where it outcrops in a black band visible from the passing train. In 1908 I wrote of "a core of hard calcareous shale (of Cambrian age) flanked by alaskite and rhyolite." That 'rhyolite' was the 'latite' of a later nomenclature. The sequence thus observed on Columbia mountain is confirmed by the evidence obtained in the deeper mines.

At the Goldfield Consolidated office I was shown the model of the mine. This is most instructive. It indicates that of the many outcrops of quartz, only a few have proved to be the caps of orebodies. The best was the silicious comb on the Combination claim; two-thirds of its length was ore, say, 600 to 700 ft. The model shows clearly that three main lode-channels have been uncovered, namely, the Jumbo, Combination, and Mohawk. The Jumbo was ore-bearing down to 250 ft. only; it was

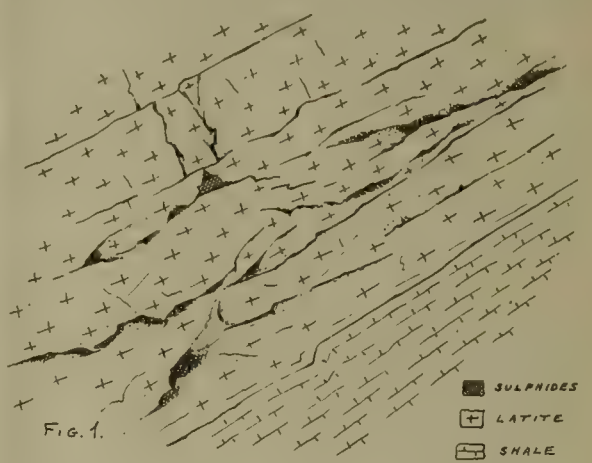

FIG. 1.

all in dacite, and did not reach the latite. The Combination ore reached down to 480 ft., that is, as far as the contact between the dacite and the latite. It was a nearly vertical vein; approaching the contact it flattened and then faded away. The Mohawk and Red Top orebodies are in a vein that dips at 40°, which is steeper than the contact between the two eruptives, but it follows their contact for 100 ft. on the dip and then penetrates the latite until the shale is reached, where the vein follows this lower contact also. The dacite is supposed to be intrusive into the latite, the upper portion of which has been eroded. The varying dips suggest a domical structure. The lower contact is the less regular, for the latite follows the irregularities of the eroded shale surface, the best ore being found where the vein is traversing the depressions in this old surface.

The deepest of the Consolidated company's shafts is the Grizzly Bear, which is down to 1400 ft. Water is being pumped out of the mine, through the Merger shaft, on adjoining property, at the rate of 220,000 gal. per dry.

Reviewing the story of the mine, it appears that ore is found in largest masses in the bends of the lode-channel where it traverses dacite. The distribution of ore is as irregular as the strike of the lode, which is no single vein, but a complex vein-system. The original boundaries of the fissuring are largely obliterated by silicification, so that 'walls' are rare, and delusive. Post-mineral faults are uncommon; only one extensive fault of this character, having a throw of 60 to 100 ft., is to be noted. The dip ranges from 30 to 45°, becoming almost horizontal in the Jumbo Extension workings where the vein reaches the shale.

The orebodies of the Combination were the most satisfactory, and they made the best showing at surface. They can be identified with the junction of the Reilly and Combination fissures, the ore extending from vein to vein. One of the rich Mohawk stopes struck 'wash' or drift 125 ft. from the surface, so that ore to that depth had probably been removed by erosion—a fortune thrown away, by Nature.

Going underground, I asked how ore was distinguished from rock. It is done by making numerous assays. The staff takes 1200 samples for assay daily. It is practically impossible to distinguish between rich ore and barren rock except in this way. Occasionally indications are noted, but they are unsafe guides. Dark streaks across the texture of the dacite and abundant alunite are mentioned as signs of richness, but the best is a line of brecciation, from one or two inches to a foot wide.

Just above the 600-ft. level of the Mohawk, I saw where the lode strikes the latite and flattens at the contact. Here a bulge of dacite into the latite terminates the orebody. Deeper the vein cuts through the latite; in this rock the orebodies, such as have been found, are rich but not so wide, although quite as long. The latite breaks cleanly but less readily, for it is finer textured than the porphyritic dacite.

On the 1000-ft. level, at a point 400 ft. west of the Grizzly Bear shaft, the visitor will see abundant green stains, indicating the presence of copper. However, much of the green discoloration seen in the mine is iron sulphate. Whether iron or copper, this sulphate is an important matter from the metallurgical standpoint. Not until the workings reached 930 ft. did the copper appear in quantity sufficient to interfere with cyanidation. The base ore is shipped to the smelters; it contains 2 oz. gold, 20 oz. silver, and 7% copper, as chalcocite and chalcopyrite. From 400 to 500 tons of such ore is being shipped from an orebody 150 ft. long and 15 ft. wide. This copper ore is characterized by the presence of famatinite, a sulph-antimonate of copper, allied to enargite, and named after an unhappy mine in the Argentine.

The lode finally strikes the shale and conforms to it, following the contact with the latite, although in places the fissuring extends into the shale itself. The rich ore is marked by needles of bismuthinite. However, plenty of bismuthinite has been found, for example, in the upper workings of the Jumbo Extension, without the accompaniment of rich ore. I saw the stoping of one of the rich veins; from 1 to 8 inches wide, averaging about 4 in., but requiring a stope 3 ft. wide, from the breaking of which the coarse waste is picked out, leaving ore assaying 2 oz. gold, 10 oz. silver, and 3% copper. A chalcocite impregnation as seen in the southeast end of the 1300-ft. level of the Grizzly Bear is shown in the accompanying sketch. Near the 1000-ft. station of the Claremont shaft, a piece of shale 10 ft. long and 3 or 4 ft. wide is seen enclosed by the latite.

These deeper workings yield patches of rich ore, but the showing is quite different from the bonanza zone nearer the surface. In the heart of the mine the orebodies were big and rich. For instance, a mass of quartz 2000 ft. long and 150 ft. wide was traversed by many veins, so that it was necessary to test it with numerous cross-cuts. One orebody yielding 60,000 tons was extracted from this mass of quartz, which reminds one of the silicious outcrops so prominent in the early days of the district before the surface had been either mined or covered with buildings.

The workings are hot, particularly the upper and older stopes, where the oxidation of the sulphides and the kaolinization of the feldspar is most pronounced. A temperature of 95 to 100°F. is reached, until free ventilation is established.

The structural geology of the shale is seen best in the Jumbo Extension, the mine that has been the subject of so much gossip, speculation, and litigation. It lies north, or on the dip, of the Goldfield Consolidated. The first ore of any consequence to the Jumbo Ex. (as it is usually known) was struck by lessees on the 790-ft. level, but it was patchy. They cut it again at 860 ft., but it was small, so they sunk the shaft to 1017 ft. and drove a level eastward, but not nearly far enough, so they failed to intersect it on the dip. Before stopping their search for the orebody, they drove a cross-cut southward to the Claremont line, thinking to cut some ore supposed to be coming down in that direction. They failed to find anything and 'quit.' The lessees having ceased to work, E. S. Van Dyke took charge for the company and extended the east drift on the 1017-ft. level, but he was unable to finish the exploration owing to a change of control, which passed to Charles S. Sprague. Under his general management, J. K. Turner, as engineer, and L. L. Dillinger, as foreman, ran the east drift 150 ft. beyond the point where the lessees had stopped it and started a raise (called Raise A) that penetrated good ore at 80 ft. above the level and 460 ft. east of the shaft. They then made other raises and subsequently extended the level itself to the present face, 950 ft. east of the shaft.

This, of course, was intelligent mining. It was based on a proper observation of the dip of the ore, which here lies at a flat angle. On the other hand, the work done by the lessees illustrates how some miners will ignore the aid of the surveyor and grope underground hopelessly, disdaining the aid of technical science.

The 1017-ft. level is in shale, for the most part, but

for some length it is underlain by a silicious rock that may be either alaskite or quartzite, probably the former. The drift had not yet reached the ore on its dip, although the face seemed to be on the edge of the latite-shale contact at the time of my visit. In this mine the lode can be seen in the latite, on the contact, and within the shale. The last phase is shown where the old shale surface rises, as a hump, into the overlying latite. Along a given cross-section the lode becomes duplicated, the lower part following the contact while the upper, 16 to 20 ft. away, penetrates the latite. Ore has been found in shale 75 ft.

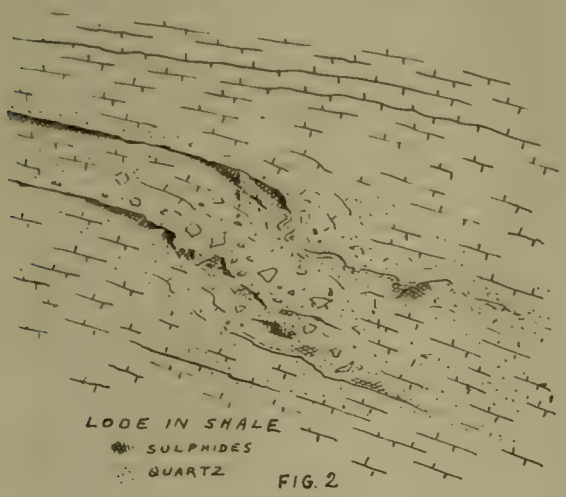

FIG. 2

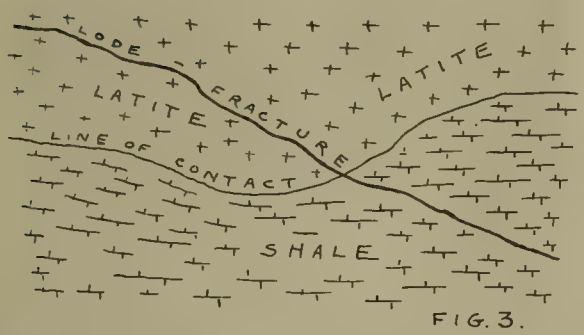

FIG. 3.

below the contact. How far it will extend into the basal formation can only be determined by further mining.

These deeper developments are exceedingly interesting. What they presage, I do not know. The evidence does not suffice to indicate the prospects of deeper mining. In most cases, in other districts, the passage of a vein-fissure from an eruptive to a sedimentary rock is not favorable. On the other hand, the lime-shale is a relatively soluble rock and as such affords a matrix suggesting the possibility of finding large replacement deposits of ore. Such orebodies as have been found are rich, although small when compared with those stoped in the dacite. When the existing complex of cross-purpose and litigation has been disentangled, we may expect to see a vigorous campaign of deepening exploration in several mines, notably the Jumbo Extension, Merger Mines, and Atlanta. The evidence to date indicates that such exploratory work is likely to be fairly productive.

Postscript. In regard to my notes on the milling methods, given in the second article of this series, I would like to add that Mr. Bosqui, in his original scheme of treatment, did not contemplate the local reduction of the concentrate. This was evolved by Mr. Hutchinson after Mr. Bosqui's retirement and departure to South Africa. The supplementary cost therefore was not included in the estimate of $2.50 per ton. However, since 1912 the tailing-loss from the treatment of concentrate has been included in the mill-tailing. The total cost of milling, including the treatment of concentrate, was $1.88 during the year 1914. Excluding the cost of treating concentrate, the milling was done for $1.606 per ton. For the first five months of the current year, the combined cost has been $1.70, and the milling alone (excluding treatment of concentrate) $1.40 only per ton.

My reference to the prospective exhaustion of the ore reserves in the Goldfield Consolidated mines has, it appears, been taken too literally. The latest official report gives the reserve at 142,000 tons, and I have no reason to doubt the correctness of this estimate, made by such an engineer as Albert Burch, general manager up to the end of 1914. Moreover, the accumulation of tailing, now available for re-treatment, amounts to 2,000,000 tons, as stated in my second article.

As regards the tangle of conflicting interests and apex litigation, it is pleasant to record that during the past month much of the confusion has been cleared by a reasonable give-and-take on both sides of the chief controversy. This has been chronicled in our editorial columns. As far as can be learned at the time of writing, a further pacification is on foot, involving the purchase of Claude Smith's interest in the Merger Mines by Messrs. Wingfield and Erickson, who appear to have buried the hatchet.

The Motor-Truck at Tonopah

The ore from the West End mine, at Tonopah, is hauled to the old Midway mill, recently remodeled, in Pierce-Arrow motor-trucks. This method has been found economical. It is a suggestion of the 'jitney' in mining, and is of practical interest. By courtesy of the manager, John W. Chandler, we are enabled to give the details:

The distance is half a mile, or one mile for the round trip, loaded with 5 tons of ore per car going and empty returning. The truck itself, when empty, weighs 8750 lb. The road is of ordinary macadam, having an average grade of 5% and a maximum of 8½%. The truck makes 28 trips per day, requiring 15 minutes for each trip. Only 1 minute is consumed in loading. The consumption of distillate is ⅓ gal. per mile; and the consumption of oil, 1 pint per day. The driver is paid $5 and the helper $4 per shift of 8 hours. The cost of repairs is $75 per month, and the cost of hauling $450 to $500. Thus the cost of hauling is 55 cents per trip and 12½ cents per ton. Distillate costs 15 cents and oil 65 cents per gallon. The expense for tires is 6 cents per mile. Hard rubber tires are used.

Advancement of Mining in Colorado

By GEORGE J. BANCROFT

When the question is asked what advancement has been made in mining in Colorado within the month, the minds of both questioner and questionee turn unconsciously to discoveries of profitable ore. This mental attitude is no doubt due to the fact that the daily press seldom speaks of any other feature of the mining industry. It is like painting one spoke of a wheel a brilliant red and leaving all the others a sombre black. The eye unconsciously follows the red spoke, in spite of the fact that every spoke in the wheel is of equal importance.

In my opinion the most important advance in mining now being effected in Colorado is of a psychological nature. It is an intangible 'something' that has possessed the minds of our mining men. It might be called the 'Get together spirit.' Never before in the history of the state have conditions been more ripe for serious litigation than they are today, but instead of litigation we are having consolidations and compromises.

During the past few months many important discoveries have been made at extreme depth. These discoveries are the logical result of the deep shafts and long tunnels, which during recent years have gradually been forced into the depths of the earth. For a time the results of these many great endeavors seemed relatively negative. Of late, however, the insiduous prying of the prospector's pick has revealed many important orebodies.

As discovery after discovery was announced, the knowing ones began to look up the question of apices. With mining claims 50 to 300 ft. wide and discoveries being made in virgin ground 1500 to 2000 ft. from the surface, one can see at a glance the possibilities for serious apex quarrels. Celebrated mining attorneys and expert witnesses began to wear the expectant look that a horse assumes when the lock to the oats-bin is rattled. I want to say, in passing, however, that these same celebrated attorneys and experts have caught the psychological infection and have worked hard to bring about compromises and consolidations, the consummations of which eliminated the possibility of drawing down big fees for litigation.

This new-born disposition to get together and avoid fights, seems to me one of the most important steps that we, in Colorado, have taken in recent years. It is not, exclusively, a feature of the past month, or the past few months, but of late we have seen several pronounced manifestations of this spirit, as, for instance, in the consolidation of the Vindicator and Golden Cycle, the consolidation of the Portland and Stratton's Independence, and the Carbonate Queen consolidation. Many other deals have been made in a quiet way and many more important ones are nearing consummation. The fact that there have been so few important mining lawsuits in the last year is the best proof of this mental change.

Opportunities were never more prolific for the locking of legal horns. Consider, for instance, the recent discoveries in the long adits in Clear Creek county. Many of these discoveries are from 1500 to 2000 ft. from the outcrops as measured on the dip of the veins. The older claims in that county are only 50 ft. wide. Most of the rest are 150 ft. wide. The vein systems are complex. A better condition for serious litigation could not be imagined, but, thus far, a spirit of fair-minded friendliness has so pervaded the atmosphere that many of the biggest wrinkles have already been ironed out and others are gradually yielding to the same process of smoothing.

The same atmosphere pervades Cripple Creek. It is reported that E. E. Chase has recently effected the settlement of a ticklish situation between the Stratton Estate and one of its neighbors. A. E. Carlton used to

MAP OF COLORADO, SHOWING PRINCIPAL MINING AREAS.

be noted for his activity and success in mining litigation, nowadays he is bending his powerful energies to eliminate such fights. He was the moving spirit in the Vindicator-Golden Cycle consolidation, and he is said to have made material progress on a consolidation that will settle for all time a dozen impending conflicts.

In Leadville the same spirit prevails, as evidenced by the owners of the Down Town mines getting together on a pumping project. In the San Juan the stronger companies have been buying up neighboring ground, particularly where apex questions were threatened.

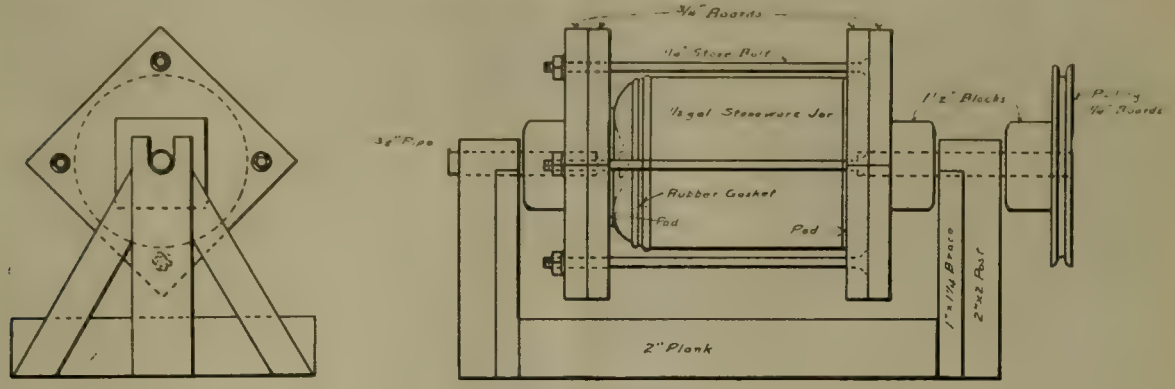
The discovery of a new ore-shoot, which may or may not produce a few tens of thousands of dollars, is heralded abroad through the land. The discovery that we can get along with a very small fraction of the litigation that formerly burdened the industry is worth many hundreds of thousands of dollars annually and is in my opinion one of the most important discoveries made in Colorado in recent times.

[Mr. Bancroft will henceforth contribute a monthly review of mining affairs in Colorado.—EDITOR.]

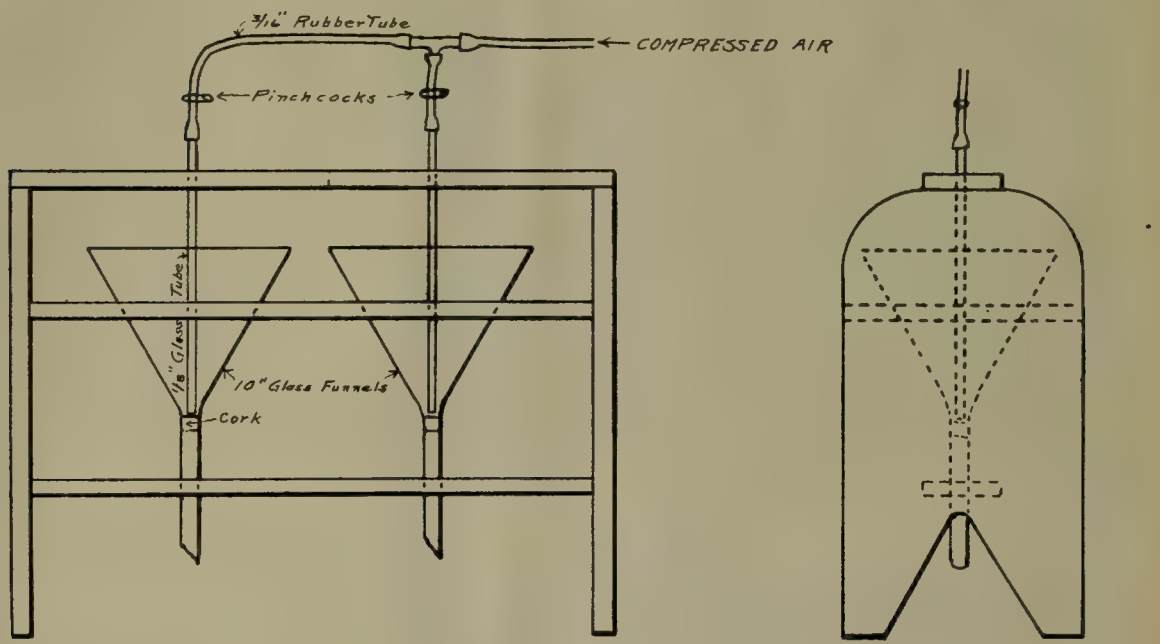
Home-Made Apparatus for Cyanide-Tests

By HORACE F. LUNT

The necessity for making cyanide tests often arises in places where there is no regular apparatus available for the purpose and where the amount of testing to be done does not warrant the expenditure necessary to purchase it. The apparatus described below was made and successfully used in such a case in making tests on 10 assay-ton lots of ore.



LABORATORY TUBE-MILL.

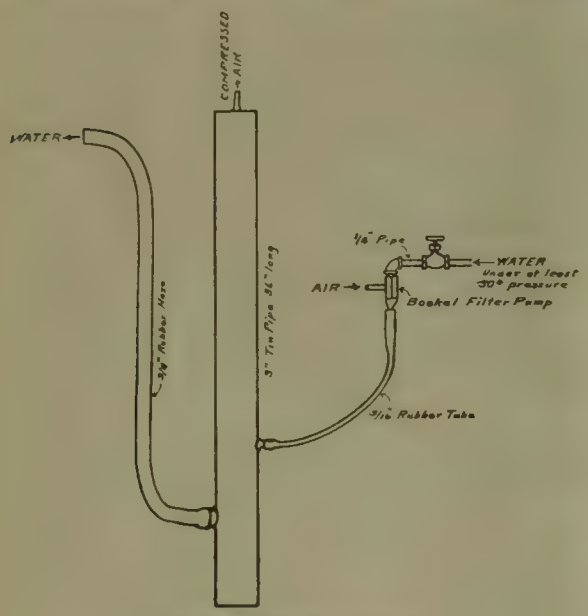


LABORATORY AGITATION-VATS.

The tube-mill is a half-gallon stoneware jar, commonly known as a 'butter-crock,' fitted into a revolving frame. The ends of the frame are made of two ¾-inch boards, nailed together, with the grain of one running at right angles to that of the other, to give stiffness and prevent warping. Quarter-inch stove-bolts clamp the jar into the frame and hold the cover on the jar. Rubber or cloth pads between the jar and the frame prevent unequal strains that might crack the jar. Blocks about 1½ in. thick nailed to the outside of the ends help to hold firmly the trunnions which are made of ⅜ in. pipe. The driving-pulley illustrated was made for round belting. It consists of three pieces of ¼-in. board nailed together and to a block. It is mounted on the end of one trunnion and serves as a base for the frame when taking it apart to remove the jar. The pulley should be fastened to the trunnion by a wooden screw passing through the block and into a hole in the pipe. The support is made of wood as shown. It should be fastened together with screws, as nails are apt to work loose. It is not heavy enough to hold itself in place when the mill is in operation, but must be nailed or screwed down.

The mill should be about half-full of pebbles 1½ to 2-in. diam. and should run at 50 to 55 r.p.m.

The construction of the air-compressor is clearly shown in the illustration. The vacuum-pump draws in air, which, with the water, enters the barrel of the compressor, where the air separates out from the water and is drawn off under pressure. The water-outlet should be lower than the top of the barrel and of ample size, so that there will be no danger of forcing water through the compressed-air outlet. Such a compressor of the



LABORATORY AIR-COMPRESSOR.

size shown will furnish sufficient air for two agitation-vats, as described below.

The agitation-vats are 10-in. glass funnels, corked at the upper end of the stems. Compressed air is introduced just above the corks by small glass tubes, as shown. The tubes can be moved in the board that supports them and the board itself can be removed when it is desired to take the funnels from the frame. The shape of the funnel, and the fact that it is transparent, makes it an ideal vessel for agitation tests.

A vacuum-filter can be made by tying a piece of filter-cloth over the top of a glass funnel, making it air-tight with paraffin, and attaching a rubber tube from the vacuum-pump to the stem.

OPERATIONS at the San Francisco Mint in May were as follows: gold received, 363,778 oz. fine, and silver 73,171 oz. The metals were worth $7,556,546. Coinage executed was valued at $175,950, including $4000 gold dollars and $6000 silver half dollars at the Exposition plant. Coin, bullion, etc., on hand at the end of the month was worth $285,149,236.61. The Mint at the Exposition contains a melting-furnace, rolls, annealing-furnace, minting-machine, scales, samples of gold and silver bars, and currency.

Cornish Mining

By W. J. LORING

The photographs shown herewith were taken some time ago by me, while on a visit to the county of Cornwall. No. 1 and 3 show in considerable detail a 16-stamp mill, operating on a very low-grade tin deposit.

No. 2 shows the old Cornish method of saving slimed tin at the East Pool Agar, which is situated between Redruth and Camborne, or more properly speaking, at the town of Carn Brea. This method has since been replaced by more modern concentrating plant, with a material improvement in extraction as well as in cost of operation.

No. 1 and 3 illustrate the 16-head mill with its old Cornish square wooden stamp, shod with cast-iron wearing members. These mills are fast being replaced by more modern methods for crushing.

No. 3 shows the method of operation, which consists of a 20-ft. overshot water-wheel, mounted on the cam-shaft. The cam-shaft is made of hollow sections of cast-iron, bolted together by means of flanges, and is about 20 inches in diameter. There are bearings at each end of this shaft, but in some mills bearings are more frequent. In this case it will be noted that 16 stamps are working between bearings.

The cams are forged iron let into holes cast in the cam-shaft. Each stamp has from four to six cams or lifters, which are set opposite the stamp to be lifted. The tappets are forged iron with a square hole that fits the stem one way while it is slightly larger the other way, it is fastened to the stem by means of a wedge, or key-driven between the stem and tappet opposite the cam-shaft.

The mortar-boxes are without bottoms, but are provided with means for changing screens in rather a modern fashion. The bottomless mortars are bedded in earth or gravel while the ore to be crushed forms the bottom. Therefore the only wearing members are the cast-iron heads or shoes, which are about 7 by 10 to 12 in. fastened to the wooden stem. When a wearing-block is worn out it is replaced, but it can never be worn out in the same sense as is the modern stamp-shoe, as will be readily understood, hence the great waste of scrap-iron as compared with the modern stamp.

The mill under consideration was running at about 23 drops per minute and crushing about ¾ of a ton per 24 hours at the time of my visit.

It may be understood that for a concentrating ore carrying tin, which is very heavy as well as very soft, much more so in fact than the gangue, this method would create a considerable amount of slimed tin.

The ore being treated at the time of my visit was said to return 3 lb. black tin per ton. Tin concentrate in Cornwall may be estimated at about 68% metallic tin.

Tin at £160, or $800, per long ton would be worth 19 pence, or 38 cents, per pound of tin. The recovery in this case was therefore 2.04 lb. tin per ton, say, 21 lb. at 38c. = 76c. per ton.

I was informed that a good living was earned by the

owners, who were all working miners, as a result of these operations.

The above is certainly a record, all things considered, for the equipment is of the crudest possible sort.

No. 2 shows the method of recovering slimed tin. This has been replaced, as I have said, by a more up-to-date method. The method shown here consists of tables of dressed wood, with the grain across the table. The tables are in series, each about 7 by 8 ft., set at a grade of $\frac{1}{2}$ to $\frac{3}{4}$ in. per foot. They are operated in the same way as the Gates and other canvas slime-strakes in California. Girls are usually employed at this work, one being shown in the picture.

Many improvements have been made at this mine since Bewick, Moreing & Co. reconstructed the company three years ago, with the result that the extraction has been increased 11%, while the total cost of operation has been reduced from 24s. to 17s. per ton. A vigorous development policy has been established, while salaries have been increased. Additions to staff, such as assayers and samplers have been made, accounting for 4s. per ton; still the total cost is only 17s. per ton.

By using the old method the cost would be at the rate of 13s. per ton, but this would be impracticable. By adding 4s. per ton by means of added staff, and more up-to-date methods, an actual saving of 7s. per ton has been made. This is a fair argument in favor of, not only up-to-date methods, but fair pay for fair services rendered, and proves the theory that low wages are not always the most economical at the end of the month.

SUPERSTITIONS and deep-rooted ideas are alike tenacious and require both time and effort for their effacement. The calling of the coal miner has long been regarded as being inherently dangerous and requiring a certain amount of recklessness and bravado. The man who would not, on occasion at least, take a chance was not a good miner. And this idea has prevailed since mining began. The movement for greater security to life and limb, therefore, is one which has to combat, not only existing physical conditions, but all the precedent, precept, and prejudice of the past. It is no wonder, then, that progress is slow, and that it often appears, even to the most sanguine, that a point has or soon will be reached beyond which material headway cannot reasonably be made. This is, however, only a feeling common to all movements toward betterment. An 80-ton locomotive was once considered as being about the largest that would ever be commercially successful. Just as the difficulties in the way of heavier rolling stock on the railroads lay not so much in the materials employed as in the preconceived ideas of the builders, so the barriers to greater safety in mining lie in the mental attitude of those concerned rather than in existing conditions.—*Frank H. Knowland.*

PICTURES OF CORNISH MINING.

The Shui-Kou-Shan Mine in Hunan, China

By H. Y. LIANG

INTRODUCTORY. The Shui-kou-shan mining district is in the Changlin prefecture of the province of Hunan, about 46 miles south from Hung-chou-fu, on the south or left bank of the Hsiang river, at an altitude of 1600 ft. above sea-level. The Hsiang river is navigable throughout the year, either by steamers of shallow draft, or by native junks, to lake Tung-ting, which has an outlet to the Yangtse river. There is a narrow-gauge railroad connecting the mine with the river-bank. When the Canton-Hankow railway is completed this mine will have direct railway connection with both those cities.

The Shui-kou-shan mine has been worked continuously for the past 200 years by the primitive methods practised by the natives of the district. On account of the crude methods and equipment employed, the mines were never worked to any great depth, and until recently there has been no extensive development.

In 1896 the governor of the province, Cheng Pao-chung, heard of the richness of this deposit and appointed Mr. Liau as the first director of the mine. At the same time Government funds were set aside for developing the mine. Mr. Liau being only a scholar, was not able to make a success at mining because of his lack of mining knowledge and experience. It was found necessary to employ local miners who had some practical experience. They sank another shaft at a place called Hsi-chiu-chang, and fortunately succeeded in striking the orebody at a depth of about 300 ft. As the shaft increased in depth, considerable difficulty was found in hoisting ore to the surface. In 1905 T. P. Sha was appointed mining engineer, and sank an inclined shaft on the south side of Hsi-chiu-chang. He also built a hoisting-plant and a pumping-station. The maximum capacity of this hoisting-plant is 200 tons per day. A sorting-house, an ore-dressing plant, and a narrow-gauge railway were soon built. At present a second vertical shaft and a new ore-dressing plant are under construction. The new plant will be completed within two years, and the total output of the mine will then be doubled.

The mine is at 26°40′ north latitude and 112°40′ east longitude. The climate is mild, the maximum temperature in summer being 104°F. and the minimum during winter 40°F. Under these conditions work can be carried on almost throughout the year.

GEOLOGY. The rocks of the Shui-kou-shan district are granite and limestone, the ore occurring near the contact. The granite is much altered by weathering. The rocks have been so metamorphosed by the mineralizing agencies which produced the ore deposits that but few of their original characteristics are distinguishable.

The granite is traversed by joints and shear-planes, which are easily seen in fresh exposures, and which form characteristic fissure-systems. The orebody is deposited as a linked vein parallel with the joints. The ore has been extracted for a length of about 1000 ft. along the strike from the southeast to northwest dipping to the northeast 80°. The characteristic fossils found are trilobites, corals, starfish, graptolites, etc. The geological horizons are Silurian and Devonian.

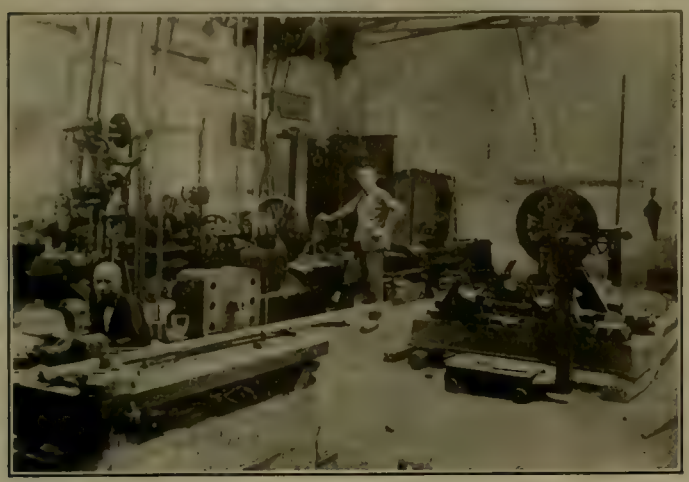
The ore is a mixture of galena, zinc-blende, and pyrite, and the gangue minerals are calcite, granite, with some dolomite. As it comes from the shaft the ore has the following average analysis:

Shaft.	Lead, %	Zinc, %	Silver, oz.
No. 1	33.90	29.40	21.2
No. 2	19.10	29.40	18.0
No. 3	23.40	23.70	18.0

PART OF HUNAN PROVINCE.

DEVELOPMENT. There are now two shafts in operation: one, called Hsi-chiu-chang, is only worked by native methods and is about 600 ft. deep: the other is an inclined shaft with a slope-length of about 800 ft., at an angle of 51°. It just reaches the third level. The size of this shaft inside the framing is 9 by 10½ ft., and the head-frame is built of 10-in. pine timber. A 50-hp. hoisting-engine has been erected at the mouth of the shaft and there is a vertical winze from the third to the fourth level with a 15-hp. hoisting-engine installed underground. The depth of the winze is about 150 ft. The length of the

drifts in the present workings varies from 600 to 900 ft. and the ore developed amounts to about 200,000 tons. The width of the orebody is 45 to 60 ft. Another vertical shaft has been started to the west, and has reached a depth of 100 ft. This will be continued until the orebody is reached at a depth of 600 ft. The size of this shaft is 9 by 15 ft. and it is divided into three compartments. The head-frame is made of 10 by 12-in. Oregon pine.



THE MACHINE SHOP.

In developing the mine practically no timbering was required in the drifts and crosscuts. In the orebodies, after putting in stulls over the drifts and placing chutes at proper intervals, stoping was continued without timbering, only enough ore being drawn to allow room for stoping operations. Therefore in the most productive part of the mine there is at all times a large tonnage of broken ore in the stopes. Square sets are used only where it is necessary, the excavations being filled with waste as the stoping progresses. The stoping method used is practically a combination of under-hand stoping and filling. As the depth of the mine increases, a large amount of water has to be handled. There are three pumping-stations underground and ten pumps have so far been installed. Power is furnished by six boilers having a capacity of 600 hp., which furnish steam for hoisting-plant, compressed-air plant, pumps, and electric-lighting equipment. Rock-drills as well as hand-drills are used. Oil lamps are used instead of electric lights in some parts of the workings. Ventilation underground is entirely by natural draught.

MILLING. The ore from the mine is separated by two methods: by hand, and in the ore-dressing plant. The hand-method is the native way of working, it is as follows: First the lumps of galena and zinc-blende are separated by workmen and broken by hammers. Then the smaller particles of galena, zinc-blende, and pyrite are separated by panning. This is done in round wooden barrels with bamboo sieves. The barrel is filled with water and the sieve, placed therein, is filled with ore, which is worked by two hands with a circular motion. The particles of galena and zinc-blende are thus separated quite thoroughly and the result attained by this process is nearly the same as with the ore-dressing plant. However, the hand-process is very slow, so an ore-dressing plant had to be built in order to take care of the increasing output of the mine. The treatment is as follows. The ore from the mine is screened in a trommel with 2½-in. holes, the over-size is crushed and the combined under-size and crushed over-size then passes over a picking belt, on which coarse clean ore and waste are picked out. The ore then passes to trommels which grade it into sizes that go to their corresponding jigs. The jig tailing goes to waste, but the middling is re-crushed by rolls, screened, and sent to the fine jigs. The tailing of these goes to waste, the middling is sent over Wilfley tables, which make concentrate and a tailing which goes to waste. No attempt has yet been made to recover lead and zinc lost in the coarse tailing.

As has been stated already, the final products obtained by hand-concentration and the ore-dressing plant are much alike. Their average analysis is shown in the table below.

JIGS IN CONCENTRATOR.

	Lead, %	Zinc, %	Silver, oz.
Coarse lead ore: (1)	73.3	4.7	29.8
(2)	58.3	11.4	22.5
Coarse zinc ore	2.3	53.4	3.8
Fine lead ore	74.8	6.6	24.4
Fine zinc ore	4.7	36.2	3.8

These five products are made by the native method.

	Lead, %	Zinc, %	Silver, oz.
Fine lead ore	73.3	7.7	29.5
Fine zinc ore	10.4	30.5	5.1

ORGANIZATION. The officers of the mine are organized

into two distinct departments and each department has its own building. One department goes by the name of the Head Office and the other is called the General Mining Office. The Head Office is divided into three departments: transportation, supplies, and miscellaneous. The General Mining Office is divided into five departments, including prospecting, mining, ore-dressing, assaying, surveying, and machinery. Each department has its own staff of officials with its own head in charge.

PRODUCTION. It is not worth while to attempt to estimate the output in the early days of the mine, but since 1905, when the hoisting-engine was erected, records have been kept and the output is given in the table below. As the rock-drills are just now coming into use a great increase in the output may be expected in the next few years.

	Galena. Tons.	Zinc-blende. Tons.	Sulphur. Tons.
1896	503	678	105
1897	807	1,832	155
1898	1,882	1,888	200
1899	3,036	4,571	104
1900	2,791	5,822	205
1901	2,260	4,806	216
1902	3,627	5,721	252
1903	3,690	5,307	85
1904	2,342	5,558	58
1905	2,079	5,187	59
1906	1,792	6,662	47
1907	1,973	10,011	34
1908	2,910	8,134	39
1909	3,088	8,483	83
1910	2,553	7,787	44
1911	4,035	9,798	97
1912	2,987	9,444	339
1913	3,164	10,319	182
1914	7,625	22,875	None
Total	53,164	134,875	2,304

LABOR. The total number of workmen is about 5000, most of whom are from the surrounding district. The scale of pay varies greatly, the highest being for underground work. The following table gives the rates of pay:

	Rate per day.		Rate per day.
Drillers	₱0.24	Bricklayers, No. 3 grade	₱0.16
Pump attendants	0.14	Painters	0.16
Common laborers	0.14	Machinists, No. 1 grade	1.50
Carpenters, No. 1 grade	0.24	" No. 2 "	1.20
" No. 2 "	0.20	" No. 3 "	0.90
" No. 3 "	0.16	" No. 4 "	0.60
Bamboo workers	0.16	" No. 5 "	0.30
Laborers	0.12	Ore-dressers, No. 1 grade	0.18
Bricklayers, No. 1 grade	0.20	" " No. 2 "	0.16
" No. 2 "	0.18	" " No. 3 "	0.14

The underground laborers work 8 hours per day, surface laborers work 10 hours per day.

TRANSPORTATION. From the mine the ore was transported formerly to Sung-pe (the bank of the Hsiang river) a distance of about 4⅔ miles by coolies at a cost of ₱1 per ton. In 1912 a single-track narrow-gauge railway was built, reducing the distance to 10 li or 3⅓ miles. The train makes 10 trips per day and has entirely displaced the coolies with all the attendant trouble. The distance by water from Sung-pe to Changsha is about 200 miles, and the ore is transported in native junks carrying cargoes of 20 to 120 tons each at a cost of about ₱1 per ton. In the spring and summer, when the river is high, transportation is very easy, the time being about four days; but in the autumn and winter, when the water is low there is great difficulty on account of the shallowness of the river. When the new developments are completed and the output increased, the mining company intends to build a number of shallow draught launches and transport as much ore as possible in the spring and summer.

GENERAL DATA. There formerly was in operation at Changsha a modern lead-smelting works, but for some reason or other it has ceased to work and the lead and zinc ore is at present sold abroad.

The police force was organized in 1912 and 70 policemen are now employed; formerly the protection of the mine was in the hands of soldiers. The police have also to undertake the work of sanitary inspection in order to safeguard the health of the people. The force is divided into groups of seven men each, under a petty officer, and the whole force is under the control of the Chief Officer of Police. They are drilled every other day for two hours and have one day in the lecture room under a trainer.

As machinists are the most important workmen, a mechanical training school was opened in 1912. There are 40 students, who are trained under a practical mechanical engineer. A series of lectures in English, Mathematics, Mechanical Drawing, and Chinese Literature is given, the course lasting three years.

Close to the Shui-kou-shan mine, at about a distance of one mile, is the Tsia Gung Chung coal mine, which was opened in 1913. The seam of bituminous coal is about one foot thick, the output per day varies between 20 and 40 tons. The coal seam is bedded in red sandstone. Prospecting work is being done through an inclined shaft at an angle of 35°, sunk at right angles to the seam in order to intersect other seams. If this coal mine is developed it will be able to cover the demand of the Shui-kou-shan mine and will decrease the present expense for fuel.

THE Eastern Pioneer Company, Ltd., which obtained extensive mining rights in Ssu-chuan through the Pritchard Morgan concession, has made arrangements with a strong financial group, consisting of S. Pearson & Son, Ltd., the Central Mining, and the British and Chinese Corporations, Ltd., to take over the control and operation of the companies' rights and interests. Fuller details will be given later.

OUTPUT of the power-plants at Panama in February amounted to 2,873,136 kw.-hours, of which the Gatun hydro-electric plant produced 2,785,830 kw.-hours. The Balboa air-compressor plant produced 129,438,628 cu. ft. of free air, compressed to 105 pounds.

DREDGING done in the Canal Zone in February totaled 1,142,448 cu. yd. This included earth, rock, gravel, and sand.

Determination of Gold in Blister Copper

By ROWLAND KING

In this method most of the copper is slagged with an excess of litharge; a large part of the remaining copper is removed by a double scorification, and the final traces eliminated by cupellation. The sample of copper borings should be thoroughly mixed on a rubber cloth and finally spread out to form a thin layer; by means of a small steel spatula a ½ A.T. (assay-ton) portion is weighed out on an analytical balance. This portion is divided roughly among five 20-gram Battersea crucibles. Into each crucible is weighed 0.8 gm. of pure flowers of sulphur; the copper and sulphur are thoroughly mixed in the crucibles and covered with from 8 to 10 A.T. of the following stock flux: PbO, 88%; Na_2CO_3, 3%; K_2CO_3, 3%; and SiO_2, 6%. The whole is then given a light cover of salt.

The crucibles are charged into a muffle-furnace which is at a low temperature and the heat gradually raised until at the end of 35 minutes the fusion is complete. Some of the excess slag may be decanted before pouring into molds. After allowing the slag to cool, the lead button may be broken free. Care should be taken at this point to see that no lead adheres to the slag; if a film of lead does remain on the slag it may be scraped off and beaten into the button. It is neither necessary nor desirable that the lead be beaten into the shape of a cube. The button at this stage should weigh about 20 grams.

Into a 3-inch Bartlett-shaped scorifier, previously heated in the muffle, the five lead buttons are placed, followed by one gram of silica. The muffle-door is closed until scorification has started; it is then removed and a good scorification temperature maintained until the slag closes over the lead; raise the temperature for a few minutes, remove the scorifier, and carefully decant the slag until the lead again shows; return the scorifier to the muffle and continue the scorification until the 'eye' of lead is about ¼-inch diameter. Raise the temperature for a few minutes and pour into a shallow mold; examine the empty scorifier for shots and particles of lead that may have stayed behind. After the pour has become quite cold the lead may be broken free. Examine the slag for adhering lead; in case there is some, it should be scraped free and added to the button, also any shots of lead that may have been found in the scorifier. After cleaning the lead of slag and beating it into the shape of a cube it should weigh about 10 gm. and be soft and quite free from copper.

The use of a good manufactured cupel is to be recommended. Bone-ash cupels, unless made with great care, are found to give slightly lower results; furthermore they are not so uniform. The Morganite patent cupel, size E, gives good satisfaction for this work. The dóre buttons, after cleaning, are parted for one hour in a water-bath in a mixture of seven parts of water to one of nitric acid; the acid is then decanted, the bead washed thoroughly with hot water, covered with concentrated nitric acid, and parted in a water-bath for half an hour. Thoroughly wash with hot water, dry, anneal, and weigh the gold. The final bead will represent ½ A.T. of the copper borings.

Silver results by this method will be found to be low, due to the excess of litharge flux used, but the results for gold will compare favorably with any method known to me. The method as given has been in use in one of the large Western smelters for a number of years. Credit is due to B. M. Snyder for the original scheme.

Novel Method of Hauling Ore Cars

An ingenious method of mine-haulage has been adopted at the Presidio mine, near Shafter, Texas. When E. M. Gleim, superintendent of the company, decided to install some kind of power method for transporting the ore from the mine to the mill, he hit upon the idea of converting a Ford automobile into a gasoline-motor, equipped with steel flange-wheels so that it could run upon the track of the tramway. He put the scheme into effect more than a year ago, and it has proved a great success, he says. The maximum grade of the railroad upon which the motor runs is about 3%. The converted car pulls three 2-ton side-dumping ore-cars, or a total load of about 16,500 lb., without difficulty. The cost of operation, including maintenance, is nominal.

HAULING MINE-CARS WITH A FORD MOTOR.

WEATHERING is more intense in tropical regions than in temperate climates, and proceeds more rapidly and to greater depths. There is also, in certain regions, a difference in the residual products.

CONCENTRATES

Readers of the MINING AND SCIENTIFIC PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

LEAD SULPHATE has now little value as a paint material, for it has been superseded by sublimed white lead.

EXPLOSIVES of high disruptive or shattering force are preferable in driving tunnels, sinking shafts, and in metal mining.

OXIDATION of ore to a vertical depth of 1550 ft. by means of meteoric waters is recorded at the Lonely Reef mine in Rhodesia.

MAGNESIUM is prepared electrolytically by passing a current through fused magnesium chloride, using some potassium chloride as flux.

PLATA is Spanish for silver; therefore silver-plate is redundant. The true meaning lingers in 'plate,' used as a synonym for silver ware.

TOOLS used in tamping gopher-holes must be made only of wood. Where boxes or receptacles are necessary, the metal used in construction must be copper.

POTASSIUM NITRATE is only found in nature to a limited extent; it is ordinarily prepared from sodium nitrate (Chile saltpetre) by a double decomposition with potassium chloride.

CALCIUM in the elemental form is made by the electrolysis of fused calcium chloride. It separates from the bath in the form of a rod, which is withdrawn as fast as it is formed.

SUITABILITY of clays for certain manufactures may be determined by submitting cones of the material to different temperatures, whereby the shrinkage, fusing point, and hardness are shown.

LOWERING OF VAPOR-PRESSURE on the dissolving of a substance in water can be conveniently measured by passing air through three saturators containing respectively water, the solution, and water. The amount of moisture in the air stream leaving each saturator is measured by absorption, and the vapor-pressure determined by computation. It is not necessary to know the volume of air used, the exact temperature, nor the exact vapor-pressure of the solvent.

MOLYBDENUM is derived almost entirely from the sulphide, molybdenite. While this mineral is widely distributed in nature, the major part of the world's production comes from Australia, notably Queensland.

POLVERDE, the name of one of the Jumbo Extension claims, at Goldfield, comes from the Spanish *palo verde*, meaning a green tree, and referring to the tree that served as a distinguishing mark near the location monument.

CARAT is a term derived from the Greek word for a hard leguminous seed. At the present time the seed of a leguminous plant, the *rati*, is used in India by native goldsmiths for weighing gold. A carat equals 200 milligrams.

ORES mined in southwestern Wisconsin are those of lead, zinc, and iron. The ores occur either in crevices, joints, and openings, or in disseminated form. The sulphide of iron and zinc-blende are usually associated, making clean separation difficult.

LOW-GRADE CYANIDE, made from cyanamid, is produced by the Cyanamid Company of America, with head offices at Knoxville, Tennessee. It is proposed to use this as a substitute for pure cyanide in gold and silver recovery, as, per pound of cyanide content, it is cheaper.

AMALGALINE is a metallic ribbon used for joining lead pipes or sheets. It is made from foil 0.05 mm. thick, composed of an alloy of tin with bismuth, antimony, and zinc. It is covered with a coating of stearine, vaseline, and methylated spirit, to prevent the formation of oxide.

LAMP-BLACK and soil when dry and finely powdered are difficult to wet. Two German investigators have shown experimentally that this is caused by the presence of a sheath of air about the particles, and not by the

presence of oily substances. In other words, it is a phenomenon of surface tension.

Potash found near Amarillo, Texas, is not a brine, but a solid. In one well, 875 to 925 ft. deep, there was 9.23% potash, expressed as percentage of the soluble portion; in another, 1700 ft., there was 10.5 per cent.

Nitroglycerin is formed from nitric acid and glycerin according to the following reaction:

$$C_3H_5(OH)_3 + 3HNO_3 = C_3H_5(NO_3)_3 + 3H_2O.$$

The term is a misnomer, as the product is a true nitrate, and not a substitution product of glycerin.

Powder-magazines should be fitted with lightning conductors. In England and Germany this is enforced by law, although no definite arrangement is prescribed. The Germans use vertical copper rods of high electric conductivity near the building. They are 36 to 80 ft. high.

Cost of bringing the Government Gold Mining Areas (Modderfontein) Consolidated Co., on the Rand, to the producing stage late in 1914 amounted to approximately $7,680,000. Ore reserves are estimated at 2,451,581 tons, averaging $5.80 per ton. The mill has a monthly capacity of 50,000 tons.

Tungsten ores often contain gold and silver, but scheelite ores especially are likely to slime badly in crushing, and the recovery of the gold and silver is attended with the loss of a large amount of the tungsten. Unless the ore contains over 3 or 4 oz. gold per ton it is not usually profitable to attempt to save it.

Where rock has been drilled for blasting, and consists of strata having variations in hardness and structure, it is advantageous to use more than one kind of powder in the same drill-hole. That part of the hole in the hardest rock is loaded with an explosive having a high rate of detonation. Less strong powder is charged into the other part of the hole.

Portland cement is all-important in concrete making. The U. S. Geological Survey states that the output in 1914 totaled 88,230,170 bbl. In 1913 it was 92,097,131 bbl. The average price of cement shipped was 92.7c. per barrel. Stocks in the country amount to 12,893,863 bbl. California and Washington made 7,092,458 bbl. Stocks in these states total 988,429 barrels.

Nickel, when present in ores, may be detected by the blow-pipe, but the method is not very satisfactory when the amount of nickel is small, as the large amount of other elements that may be present are likely to obscure the nickel reaction. The most sensitive test is that with dimethylglyoxime. If a little of this reagent is added to a solution containing nickel, then ammonia to slightly alkaline reaction, and the solution boiled a red crystalline nickel salt of dimethylglyoxime is formed. In this way 1 part of nickel in 400,000 parts of water may be detected. If much cobalt is present hydrogen peroxide must be added after the ammonia and the excess boiled out before adding the dimethylglyoxime.

Linseed oil is sometimes adulterated with mineral oils or non-drying oils, such as soya-bean oil. The presence of the former is easily detected, as they remain in the unsaponifiable residue obtained in the course of an ordinary analysis; the presence of the latter may be inferred from low specific gravity and iodine tests.

Capacity of Blake rock-crushers may be computed as approximately equal to 2 tons per 24 hr. per square inch of feed-opening, when crushing to pass a 2-in. ring, the speed of the crusher being 275 revolutions per minute. For example, an 8 by 10-in. crusher will have a capacity 8 by 10 by 2 = 160 tons per 24 hours, or approximately 7 tons per hour.

Sodium carbonate was obtained, previous to 1791, from natural deposits and the ashes of marine plants. The Leblanc process, invented in 1791, enables it to be made from common salt. The sulphate is first formed, is reduced to the sulphide, and is then converted into the carbonate by lime carbonate. This was displaced by the Solvay (ammonia-soda) process in 1863.

Carnotite from Colorado and Utah, containing from 1.5 to 33% U_3O_8 has been tested by the U. S. Bureau of Mines to determine the radium-uranium ratio. Results showed that the ratio is identical with that of pitchblende in all large quantities of well-sampled ore. This appears to be true regardless of the locality of the deposit or composition of the ore. There is no justification for regarding the radium-uranium ratio in commercial quantities of carnotite as being low or in any way abnormal. In well-sampled carnotite the uranium content of which is accurately known, the radium content is not less than in the proportion of 1 part radium to 3,000,000 parts of metallic uranium.

The pitchblende of Cornwall occurs mostly as one of the minerals of the copper deposits, though it occurs also with tin and other deposits, according to R. A. F. Penrose. With it, in addition to the copper, iron, and other commoner materials, are generally associated the rarer minerals of the region, such as native bismuth, nickel, and cobalt, sometimes lead and silver, arsenic in the form of mispickel, and fluorspar. Other uranium minerals are sometimes associated, such as autunite, torbernite, zippeite, uraconite (uranochre), and other compounds, probably the products of the alteration of pitchblende. In fact, all the ores near the surface are altered, and the pitchblende is likely to be coated with, or even entirely replaced by, alteration products; but below, the black pitchblende appears, associated with sulphides and other unaltered minerals.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LONDON

SPELTER: FUTURE IN AUSTRALIA, ENGLAND, GERMANY, AND THE UNITED STATES.—NEW SUPPLY FROM SIBERIA.—MOLYBDENUM. —TIN.

Zinc men would find much to interest them in London these days. Prices of metal are high, as will have been noted from the daily quotations, and there is a lively scramble for supplies. At the same time the major interest is in the future, the re-adjustment of smelting conditions, and trade relations that will occur during or following the War. It is hardly likely that Australian zinc ores will find their way again in large quantities to Germany. Even if the existing contracts be held unbroken, their remaining life is not long, and if the War ended tomorrow, resumption of normal trade currents would be slow. There is a strong feeling favorable to the establishment of British smelting works to treat Australian ores, but so far nothing definite or practical has resulted. The reason is that, speaking broadly, the cost of zinc smelting in Germany, Great Britain, and the United States is about the same. Also it is not a particularly profitable industry. To transfer therefore to England that part of the German spelter industry that has been founded on use of foreign ores, demands something more than mere sentiment. The Germans gave ship subsidies for a period long enough to get the business going, and German plants, as is well known, enjoy special export rates on the German railroads. It has so far proved impossible to get an English subsidy to throw the current of zinc concentrate to Great Britain, while the railway haulage is here too small a factor to matter. England affords a large permanent market for spelter, but a protective tariff, which naturally occurs to an American in this connection, is politically unthinkable for the present at least. There are two possible lines of development. The United States may, by establishing seacoast plants and smelting in bond, capture the trade. If so, American capital will need to be forthcoming to the extent of $20,000,000 to $30,000,000, serious readjustment must be made in steamer lines, a market must be found for a largely increased output of sulphuric acid, and probably a market for wool developed. Concentrate and wool form a heaven-born combination for steamers comparable to pig iron and coke. But what is to form return cargo to Australia so as to permit the low freight rates that are essential? These form interesting subjects for speculation. In the meantime trial shipments of concentrate have been made to the United States. On the terms of purchase these shipments should show a profit, since the price of spelter has gone up, and the Americans get the increase beyond £30 per ton. It is far from certain that Australians will be willing to sell heavily on the basis of the existing contracts. The second possibility is the re-establishment of the Belgian zinc-smelting industry. Before the War Belgium was producing about 220,000 tons of spelter per year, exporting most of it. Up to the present the plants at Liege and elsewhere in Belgium have been little injured. Indeed, a number have been kept in commission, though at a reduced rate of output. Since there is a large surplus of spelter within the German lines, this has been done mainly with the purpose of affording work to a part of the staff and workmen. The Germans have forbidden the export of this metal, and there is accordingly a growing stock to be reckoned with. Many of the Belgian works are controlled by German firms, but the English are counting upon succeeding to this position of dominance at the end of the War in one way or another. It is impossible to say what may happen to the existing works when the Germans leave Belgium. If they remain as they are, resumption of production will be relatively easy and prompt. If they are destroyed, it is probable that English capital will be promptly provided for their re-building, since nothing seems more certain than that commercial ties between Belgium and England will be closer hereafter.

Russia in the meantime affords an open field for the employment of British capital in zinc smelting, as in many other industries. The Irtysh Corporation, controlled by the Russo-Asiatic in which H. C. Hoover, R. Gilman Brown, D. P. Mitchell and other Americans are prominent, is now building a zinc smelter in the Altai country to treat ore from the Ridder mine. Two blocks, the first of 14, are being erected this season. The plant is thoroughly modern and includes considerable American equipment, as well as the best American practice. L. Radkin, who has gone to Ekibastus to superintend operations, was recently manager for the Sandoval Zinc Co., at Sandoval, Illinois. Since there is a Russian tariff of almost one cent per pound on spelter and a rapidly growing market, the new enterprise should be successful from the first. The initial production will be about 24 tons of spelter per day. The ore treated is a complex mixture of sulphides. The retort residue is to receive further treatment along the lines developed at Bartlesville, Oklahoma, in connection with Butte & Superior ores, described in the MINING AND SCIENTIFIC PRESS in 1914 by E. H. Leslie.

Minor metals attract considerable attention nowadays. The necessity for speed in lathe-work in connection with armament contracts, has made a large demand for tungsten steel, and prices for tungsten ores have accordingly been soaring. Molybdenum, which may be used for the same purpose, has also been

IN NIGERIA, WEST AFRICA.

in demand, but prices have recently broken badly. The explanation offered is that the principal demand has been from France, where molybdenum is used as a stabilizer in the manufacture of high explosives. At the beginning of the War there was a panic over possible shortage of supply, and prices were run up above their proper level. Now that the supply is assured they have receded. As a matter of fact it is not even certain that the material is necessary in explosive work, but everyone is too busy to study the matter now, and no one can afford to take chances.

Nigerian tin share transactions have been few. The Anglo-Continental company estimates an output of 400 tons in 1915. Drilling shows about 6014 tons. Tin ore from Nigeria arriving in England in April totaled 916 tons, equal to 641 tons metal.

All of the reports of Rand companies for 1914 have been issued. They are always of interest. In the next letter the Crown Mines will be discussed.

CRIPPLE CREEK, COLORADO

GOLD OUTPUT. — DRAINAGE ADIT. — INDEPENDENCE LEASES.— MERGER RUMORS.—LOCAL FEELING.

The following is the output of the district for May, as compiled from the reports of the mills and smelters:

Plants.	Tons.	Per ton.	Total value.
Smelters	4,750	$55.00	$261,250
Golden Cycle	30,000	23.00	690,000
Portland (valley)	12,000	19.50	234,000
Portland (district)	19,450	2.96	57,572
Stratton's Independence	8,387	2.78	23,314
Free Coinage	2,252	4.00	9,008
Dante	2,000	2.00	4,000
Wild Horse	1,000	3.50	3,500
Total	79,839	$16.06	$1,282,644

A water-course giving about 2000 gal. per minute was cut on May 29 in the breast of the Roosevelt drainage adit, a short distance west of the Elkton shaft, at a depth of about 1800 ft. The flow from the portal of the adit is now nearly 12,000 gal. per minute. Were it not that this is the wet season of the year, and considerable surface water is running, a decided lowering of the water-level in many of the mines would be apparent. Work is progressing rapidly in the face. As the formation is gradually changing from granite to breccia, fast work will be accomplished, as the ground will break more easily.

It is now fairly definitely understood that the Portland company will continue to lease the Independence after it takes it over. Many applications are already on file for blocks of ground. The system in use will be the 'split-check.' It is hoped that considerable development will be undertaken. Arrangements are being made to handle the Portland No. 1 dump at the Independence mill, where the tonnage treated each month will be greatly increased. The Portland thus once more takes its place as the big mine of the district, and good earnings and dividends are assured for several years to come.

There has been no further news concerning the proposed Vindicator-U. G. M., etc., merger this week, though the general impression is that something is on foot and that an announcement may be made any time. Since the Portland-Independence deal was so quietly put through, the public has been alert all the time, and would not be unduly startled if other mergers were sprung.

The general tone of the district is optimistic. Leasing is increasing, and the low-grade mills assure a continued era of prosperity. More men are gradually finding work both with lessees and companies. Dump-leasing is calling for a number of men during the summer season and, in general, June should be a big month.

JOPLIN, MISSOURI

ORE PRODUCTION — LOWER LEVEL MINE. — STOTTS CITY DISTRICT. — ACTIVITY AT AURORA.

Shipments of blende from over 20 districts of the region are nearly 6000 tons per week. The grade is averaging about 57% metallic zinc, and 3 or 4% iron. In some of the districts the ore is even better than 60% with no iron. Non-lead-bearing ores are in greatest demand, and command the highest price. Webb City continues to be the heaviest producer with a weekly shipment of over 1,300 tons of blende. Joplin is second, and Miami, Oklahoma, third.

At Sarcoxie, 20 miles east of Joplin, the Bearcat Mining Co. has been re-organized, and is now operating under the name of the Lower Level Mining Co. As the name implies, new work is being conducted at a greater depth than previously. The mine was not successfully operated for any great length of time by former companies, but the present owner believes it has an orebody that will prove profitable, especially at the present price of zinc ore. When the mine was operated before, zinc ore was selling for only $40. In the new company are J. W. Boyd, on whose land the mine is situated; J. J. Stephenson, of Pittsburg, Kansas; and George Spiva and Sam Tamblyn, of Joplin. Two shafts are into ore, one at the mill where work is conducted at a depth of 278 ft., and one 300 ft. southwest of the mill where operations are at 160 to 200 ft. The ore in the upper ground occurs in white flint, and in the lower ground in dark selvage. The mill is the largest in the Sarcoxie district. It has a capacity of 400 tons per shift.

Stotts City, 18 miles northeast of Joplin, is enjoying a revival of mining that already has resulted in one large new concentrating plant. The mill is being built by Grant Hart and Loren Seneker, who have 200 acres of the Hill land under lease, 1½ miles south of Stotts City. They sank a number of drill-holes which showed zinc ore from a depth of 140 to 200 ft. The formation was so nearly uniform in appearance, judged by the clippings from the various drill-holes, that a shaft was sunk and drifts have been extended into the ore. It is reported to be exceptionally good. The plant is to have a capacity of 300 tons per shift. G. F. Cole & Co. are drilling, with fair success, on the Hill land, ½ mile west of Stotts City. The members of the company are from Grand Junction, Colorado. Friedman & Co., of Springfield, Missouri, are drilling on the Elliott land, 3 miles southwest of Stotts City, and have cut fairly good 'shines,' but no ore rich enough to warrant the sinking of a shaft. Efforts are being made by W. G. Nealy, J. W. Downing, and others of Stotts City to locate the lost run of ore at the old Stotts City mines, which were such heavy producers several years ago. A fissure vein of ore which was being mined at that time suddenly came up against a blank wall of limestone. Geologists say that the discontinuance of the run was occasioned by the faulting of the ground, and that the continuance will be found on one side or the other from the former workings. Several drill-holes have been put down in both directions, but the orebody has not yet been found.

Aurora, 40 miles east of Joplin, is the scene of more activity than has been seen there since 1912. It is now producing five carloads of calamine each week. It soon will be shipping blende, as work is being resumed at several of the old deep mines where good deposits of sphalerite were found. Drill strikes of importance have been made on the W. T. Flournoy land, two miles northeast of Aurora by Mr. Flournoy, Larry Brunk, C. A. Gott, Bert Gardner, H. R. Raitinger, Al Ruppell, Otto Schmook, and John Alexander. A contract for the construction of a concentrating plant of 150-ton capacity per shift has been let. The mill will be ready by the time the new shaft, 5½ by 7½ ft. in the clear, is in ore. The drill-clippings were considered as rich as any ever found in the Aurora district. Ore in the first hole was cut at 87 ft., and continued to 152½ ft. The average blende content was between 7 and 8%.

In the second hole the ore was cut at 85 ft. and continued to 155 ft. It assayed 9%. Other holes sunk farther away failed to show the ore, but the extent of the deposit as revealed in the first two holes leads the operators to believe that they have a sufficiently large formation to warrant the construction of a mill. Three eight-hour shifts are sinking the shaft.

PLATTEVILLE, WISCONSIN

ZINC ORE CONDITIONS IN MAY.—PRODUCERS AND SMELTERS.—'SPELTER-TRUST.'—PRODUCTION.—DISTRICT OPERATIONS.

May was one of the most sensational periods ever experienced in the zinc and lead-mining industry in southwest Wisconsin. The month ended with a Federal government investigation of the spelter situation. With such high prices for spelter it might be inferred that zinc ore would keep step with the rise; but the contrary was true. Wisconsin zinc miners are to a great extent handicapped by the fact that the output of their mines varies from extremely low to high-standard commercial spelter ore. Buyers showed no inclination during the month whatsoever to submit bids on the medium and inferior grades, instructions apparently from headquarters to all seeking ore restricting buying to high-grade ore exclusively. Many of the larger operators tied up under contract arrangements were bitter and loud in their denunciation of settlements based on certain journal quotations, claiming there was one basis for the producer of zinc ore and another for the smelter, who is the only one making money out of the present situation. On the part of the zinc-ore miners there appeared no disposition to curtail production. With no demand for the lower grades, a surplus rapidly accumulated. On June 1 this was found by actual observation to exceed 8000 tons, the largest stock ever held. To add to the discomfiture of miners, their demands for better prices was met with the drastic response of 9000 tons of Australian zinc concentrate from Broken Hill. The first of this reached Kansas and Oklahoma smelters about the middle of May. These shipments, it was announced, were only the forerunners of a steady flow of Australian ore into this country. The Broken Hill districts produce annually about 500,000 tons of about 50% concentrate, which formerly went to Belgium and Germany. Mining men argue that if shipments from Australia continue in volume, they will paralyze, if not utterly destroy zinc mining in the United States. And as if this were not sufficient to harrass and discourage producers of zinc-ore, smelter-agents intimated boldly that the production in the United States was 1000 tons in excess weekly of that necessary for smelter requirements. Regardless of all unpleasant annoyances, Wisconsin for the first time in 20 years witnessed the introduction into the field of buying interests operating exclusively in the Missouri districts. Notably active were agents for the Edgar Zinc, Lanyon Zinc, and Picher Lead companies, all demanding high-grade product. Under the spur of accelerated competition, prices for zinc ore advanced, closing the month on a basis of $75 per ton, for 60% metal content. The Picher Lead Co.'s buyer yielded concessions on lead up to 2 points; iron, 3 points, and lime in quantity. Local buyers representing Illinois smelters long resident in the field were quick to meet the figures offered by the 'stranger' to the city, much to the delight of ore-producers. Their contention of a 'spelter-trust' seems to have been well carried, on these later advances still $5 to $10 per ton under current quotations obtaining in the last days of the month in the Missouri zinc region. Agents of the Department of Justice, acting under orders of Attorney-General Gregory in charge of anti-trust litigation, made diligent inquiries among iron and steel consumers and Western zinc-ore producers. Complaint was made at the Department by Missouri congressmen. Ore producers claimed that certain smelters were forcing down the price of raw product which they buy, despite the advancing price of the finished product which they sell. A request for the names of complainants was refused. The Government agents gathered evidence which tended to show clearly that the high price of spelter is artificial, and cannot be explained solely by large exports from this country. If sufficient evidence can be obtained it was said that the Department will start anti-trust proceedings. To one acquainted with the investigations formerly conducted in the zinc industry, it is needless to say that the one now being made will go the way of all the others, a premature and obscure burial.

According to the best informed mining men in the region, there is now only one satisfactory solution out of the present predicament for low-grade producers; that is the more general introduction into the field of calciners and electro-static separating-plants. Most of the zinc ore out of the field during May came from the latter. They have been working night and day. The maximum capacity represented in the field is inadequate to handle present production.

While spelter continued to hold the center of the stage, lead was not slow in claiming attention during the month, and made substantial gains after remaining all through April at $4.20 per cwt. St. Louis; this price being advanced to $4.90 May 29. Sellers then reported a large number of inquiries and demands that involved shipments as far ahead as next September. Sales and shipments were light. A fair tonnage is stored.

Pyrite was in better demand at better prices, and separating-stations unloaded a quantity of fines, while coarse ore from the breakers came in greater quantity than for some months.

Producers of carbonate of zinc ore witnessed astonishingly high quotations, 40% ore ranging from $40 to $50 per ton. No offers were made. Shipments were light. In this branch of the industry, unusual activity was shown in the northern districts of the region where several thousand tons of finished product lies in bins awaiting offerings. The advent of warm spring weather nerved miners to go ahead and clean up last winter's mine-run material.

Shipments of ore were as follows: zinc, 23,018,000; lead, 1,098,100 lb.; and pyrite, 3,145,060 pounds.

A brief survey of the more important events in the region by districts is as follows: The New Jersey Zinc Co. finished up in the Highland district, leaving five complete power and milling-plants to their fate. The lands held by the company will be cut into small tracts, and sub-let to local miners.——Contracts between operators and the New Jersey Zinc Co. which expired during the month were not renewed. Miners will turn to hand-cobbing ore in order to make high-grade ore, which alone is in demand.——At Linden many new mines are being developed.——The Mineral Point Public Service Co. increased its power capacity and began extending its transmission-lines north to the most northern areas of the region.——The Wisconsin Zinc Co. developed a new mine at Platteville, known as the East End; the Klar-Piquette Mining Co. resumed operations after two years' idleness; and the Edgar Zinc Co. entered the field by buying at this point.——The Campbell Separating plant at Cuba was started. Increased deliveries were made from here of high-grade ore exclusively.——The Benton district reported large discoveries of zinc ore at several points through mining and drilling. The Vinegar Hill Zinc Co. ushered in a new producer with new equipment. It is to be known as the Kittoe. The Hird mine was unwatered after a two years' fight to get into the ground, and the main shaft was being sunk to ore toward the end of the month. The Indian Mound Mining Co. introduced a new mine to be known hereafter as the Monroe. Longhenry Bros. financed a new property and started breaking ore. The Fields Mining & Milling Co., of Chicago, completed a new $60,000 power and concentrating equipment. They started men underground on a discovery which it is estimated will produce 1500 to 2000 tons of concentrate per month.——The Champion mine at New Diggings produced 450 tons per week. At the end of the month it had stored 2500 tons of concentrate.——The Wisconsin Zinc Co. developed a new mine on the Winskill land near Shullsburg, and completed a new 200-ton plant. It was producing 200 tons of ore per week, which was being stored in bin. The

Cleveland Mining Co. introduced a new producer with a new modern equipment, and was making 150 tons of ore per week which was being shipped to the Mineral Point Zinc Co. The Federal mine had a good deal of ore in new ground and was shipping four cars per week, besides storing some.——Richard Stovall was made field superintendent for the New Jersey Zinc Co., with headquarters at Galena, Illinois.——A score of drilling machines were active in the southern districts of the region throughout the month with fairly good results. One important development was reported by the Wisconsin Zinc Co. on the Sally Waters property at New Diggings.——Several new mines were being developed in the Galena district from which large returns are expected.

[The value of mine output of silver, copper, lead, and zinc in Wisconsin for the calendar year 1914 was $3,291,437. The corresponding value for 1913 was $3,536,528, according to the U. S. Geological Survey. Lead concentrate sold declined from 2532 tons, valued at $125,197, in 1913, to 2028 tons, valued at $85,196, in 1914. The sphalerite concentrate sold increased in quantity from 95,540 tons to 108,535 tons. The value of the sphalerite concentrate was only $1,924,126 in 1914, compared with $2,053,341 in 1913. The quantity of the zinc carbonate concentrate sold declined from 3123 tons to 2787 tons. The metal content of the galena concentrate was 372 tons less than in 1913. The recoverable zinc content of the sphalerite and zinc carbonate concentrates increased 1003 tons over that of 1913, but the value was $198,794 less. The average tenor of the sphalerite ore marketed was nearly 3% lower in 1914 than in 1913, and the average price paid for the concentrate was $3.83 per ton less. The Benton district was again the largest producer of both lead and zinc concentrates, followed by Hazel Green and Livingston. All three districts produced more ore in 1914 than in 1913. The U. S. Bureau of Mines has issued Technical Paper 95, compiled by Clarence A. Wright, describing mining and milling in Wisconsin. An abstract will appear in another issue of the PRESS.

The Wisconsin Geological and Natural History Survey at Madison has recently published Bulletin No. XLI, Economic Series No. 18. This is entitled 'A Study of Methods of Mine Valuation and Assessments,' with special reference to the zinc mines of southwest Wisconsin, by W. L. Uglow. This interesting discussion covers 73 pages. The nine chapters include the following discussions: purpose of the paper, taxation of mining property; peculiar conditions in the zinc district which have an important influence on the problem of valuation and assessment; the hypothetical zinc mine, basis of subsequent discussion; significance of the term 'full cash value' or 'rational valuation,' from the point of view of the general property system of taxation; the standard *ad valorem* method; the Finlay *ad valorem* method; the Arizona and Colorado methods; gross receipts and tonnage-tax method; Wyoming, South Carolina, Nevada, British Columbia, and Ontario systems; the equated-income method; general comparison of the salient features of the Finlay and equated-income methods; and a general conclusion. This is no place for a discussion of such an important subject, but mine operators will find it useful for taxation reference.—EDITOR.]

ROCHESTER, NEVADA

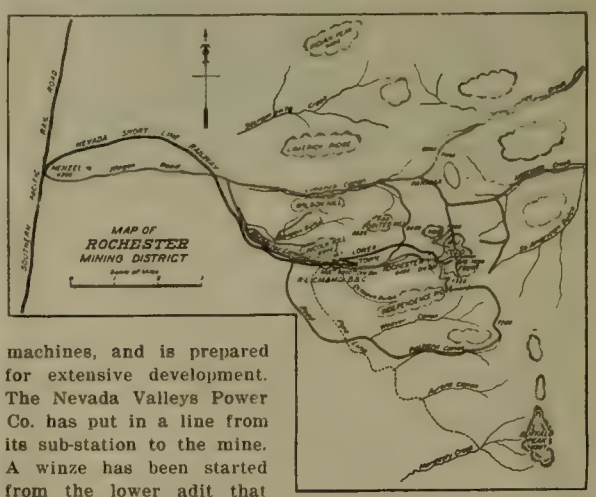
GENERAL CONDITIONS.—NEW MILL.—ROCHESTER CONSOLIDATED.—ORIGINAL ROCHESTER, LINCOLN HILL COMPANIES.—LIMERICK CAÑON AND BUENA DISTRICTS.

This district is quiet. It seems to have settled down to the stoping of ore opened in the leases, which will occupy the new mill for more than a year. There does not seem to be much new business in sight, although there are numerous promising prospects. The owners have been so loth to sell that capital seems to have become tired of coming in to look at them and try to negotiate for the properties. The lessees were so much in debt that the starting of the mill and payment for about $80,000 worth of ore has not had any visible effect on the money conditions here. Possibly somewhat later there may be more life developed.

The custom mill is treating from 110 to 120 tons per day. Two shipments of bullion have been made, the first of 59 bars, of an estimated value of $32,500, and the second of 38 bars of $26,600. Ore comes from the Codd, Big Four, and Four Jays leases on the Rochester Mines Co.'s ground on Nenzel hill, and the Cole-Huntington, Colligan, and Stoker leases on the Rochester Weaver ground. These two companies have arranged a consolidation to be known as the Rochester Consolidated Mines Co., as mentioned in the PRESS. The Weaver ground is to the south of the Rochester Mines, and on the southern slope of Nenzel hill. The ore in the Weaver contains much more gold than the leases to the north, although the Codd lease has some gold in the lower levels.

The Rochester Mines Co. has started an adit in the ground of the Original Rochester Co. by permission, to cut its vein. The adit starts from near the orebins, and 1000 ft. of driving is expected to cut ore at a depth of 1600 ft. on the dip of the vein, which dips with the hill.

The Lincoln Hill M. & M. Co. has optioned a controlling interest in its shares to New York people, who have made a first payment. The company has purchased a compressor and six



machines, and is prepared for extensive development. The Nevada Valleys Power Co. has put in a line from its sub-station to the mine. A winze has been started from the lower adit that will be sunk to a depth of 200 ft. In cutting the station for this winze a cross-vein was found containing a small streak of rich ore, and three feet of soft vein-matter which averages $18 per ton. A new wagon-road is being built from the mine to the mill. It will be much shorter than the road now in use, and will have a good average grade.

The Nonpareil mine has a shipment of high-grade ore ready to send to the Lincoln Hill mill for treatment.——The Abe Lincoln No. 2 has opened a small vein of good ore. So has the Casey Jones.——Lessees are extracting shipping ore from the claim west of the Packard.——Good ore is also being opened in claims north of the Packard.

The owners of claims in upper Limerick cañon are starting work for the season, both at the placers and veins. Just across the ridge near Indian creek, some promising gold veins are being opened. W. F. Rice, George Smith, Edward Beal, and J. M. Savage have secured locations on two veins that are showing considerable improvement with development.

In the Buena district further work is encouraging. The veins are showing persistence with depth. The large bodies of good milling ore have induced several companies to take options, with the probability that one or two mills may be installed this season.

The consolidation of the Rochester Mines and Rochester Weaver companies should result in more economical work at these properties.—Rich ore is coming from the Packard still.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Fairbanks

According to W. J. Maloney, territorial mine inspector, the outlook in the Fairbanks district for the current season is better than last year. There is more activity everywhere.—— The erection of a telephone line from Fairbanks to Tolovana is contemplated.

Juneau

A 3000-ft. adit is to be driven at the Alaska Gold Belt company's property at Sheep Creek basin. Arthur Reandeau will be in charge.——A Hardinge conical ball-mill is to be installed in the 700-Ft. mill of the Alaska United.

Ketchikan

The copper deposits of the Ketchikan district were known to the Russians before the acquisition of the Territory by the United States. There was a crude attempt to develop them as early as 1880. It was not until 1901, however, that systematic mining was begun and not until 1905 that a large annual output was made. Up to the end of 1913 the copper mines of the Ketchikan district had produced about 22,640,000 lb., valued at $3,760,000, and $500,000 worth of gold and silver. Most of the mines of the district lie at or near tidewater. There is an abundance of timber, and the relief favors the undercutting of the orebodies. While there are as yet only a few producing mines, there are many undeveloped copper prospects which give promise of containing commercial orebodies. Many of the copper deposits show an irregularity of occurrence that is unfavorable to cheap exploitation, but otherwise the conditions are favorable to low mining costs.

A report on the mineral deposits of the Ketchikan district was published by the U. S. Geological Survey in 1902, and a more complete account was issued in 1908. Meanwhile, in view of the important mining development, a more detailed study was entered upon by C. W. Wright, of the Survey. The results of this work, which covered the most productive part of the field, have just been made public by the Survey in a report by Mr. Wright entitled 'Geology and Ore Deposits of Copper Mountain and Kasaan Peninsula, Alaska' (Professional Paper 87). This report is accompanied by detailed geologic and topographic maps, and includes descriptions of the copper deposits and their geologic occurrence. It deals primarily with the copper ores, which are at present the most important mineral deposits of the two areas examined. However, there is also much iron ore which is undeveloped except incidentally to copper mining.

Seward

Construction of the railroad from Seward to Fairbanks has attracted many men to the former district. There are said to be 1500 men at Ship Creek, where the Government has established a supply-base for the line. Only about 100 are employed there. Not over 500 will be needed this year.

ARIZONA

The mineral deposits of the Santa Rita and Patagonia mountains are described by Frank C. Schrader and James M. Hill in Bulletin 582 of the U. S. Geological Survey. With maps, illustrations, and index the work covers 373 pages. The area is in the southeast part of the state, in Pima and Santa Cruz mountains. The country is desert, and is at a general elevation of 4800 ft. It is 20 miles southeast of Tucson, and 30 miles west of Bisbee. Two railroads operate partly in the district. The rainfall averages about 14 in. per year. The summer is hot, winter mild, climate healthy. Several cañons contain plenty of timber. Mining has been done there since 16th century. Since then, work has been irregular, of later years due to the metal markets. Yet a great deal of development has been accomplished. From 1903 to 1912, inclusive, 178,108 tons of ore yielded gold, silver, copper, lead, and zinc worth $1,068,582. Copper accounted for over half of this amount. Previous to 1903 the production is considered to have been large. The deposits of the area described are principally fissure veins, and replacement or contact-metamorphic deposits containing gold, silver, copper, lead, zinc, tungsten, and molybdenum. Sulphides generally begin to appear rather near the surface, but the lower limit of the oxidized zone is irregular and ranges from less than 100 to 300 ft. below the surface. Water occurs in most of the mines, and the ground water-level in general stands at depths of about 250 ft. The deposits represent at least two distinct periods of mineralization, and occur in two sharply contrasted groups that differ considerably in age. The report gives considerable detail of the principal properties and other interesting points.

Cochise County

The report of the Commonwealth Mining & Milling Co. for the eight months ended December 31, 1914, has been issued. Edgar A. Collins, general superintendent, reported as follows: estimated reserves total 96,167 tons, assaying $4.95 per ton. This is a decrease compared with the previous report. Only 10% of the development footage was in profitable material. At the same time the outlook is encouraging. Extensive prospecting is under way on No. 3, 5, 7, and 8 levels. This is important work. The mine makes 1350 gal. of water per minute. The mill treated 70,560 tons of ore averaging $5.167 per ton. Residue contained $1.028 per ton. Total revenue was $299,274. Costs totaled $3.663 and profit 57.2c. per ton, equal to $40,386. Capital expenditure and interest left a deficit of $5042. C. Phillips is mine foreman, F. A. Voorhees mill superintendent, E. Hinrichs master mechanic, and F. L. Bryant secretary-treasurer.

Gila County

(Special Correspondence.)—The Scorpion shaft of the Inspiration is producing about 1000 tons of ore per day. A steel and concrete miners' change-house is to be erected. This will be near the main west shaft. It will contain a first-aid room. The coarse-crushing plant is ready for work. It consists of four large gyratories and eight 48-in. Symons disc-crushers. Heavy pan-conveyors feed the former machines, belt-conveyors the latter. Magnets will extract pieces of steel from the ore. Two inclined 36-in. conveyors will deliver the ⅞-in. ore to the Webster Gulch storage-bins of 25,000-ton capacity.

The Iron Cap is sending four carloads of ore per week to the El Paso smelter.——The Arizona Commercial sends 175 tons daily to the Old Dominion smelter. Development at 1200 and 1300 ft. is satisfactory.——In May the Gibson mine yielded about 200 tons of ore. Lessees G. Zapp and L. Riddle extracted 40 tons of 38.18% copper ore. Other lessees are doing well. The district around the Gibson is highly promising.

Miami, May 28.

Mohave County

(Special Correspondence.)—The United Eastern mine in the Gold Roads district is a highly promising prospect. The shaft is in andesite; it cut a vein dipping about 75° north at a depth

of about 200 ft. The mineralization was not very strong at this point and the values were low. At a depth of a little over 300 ft. there was some five to seven feet of ore carrying $12 to $15 in gold, and a depth of 460 ft. there was a little in excess of 20 ft. of ore averaging slightly under $30 in gold, and at a depth of about 560 ft. there was a width of 22 ft. averaging somewhat over $30 in gold. The mineralization is much stronger on the 460-ft. level than on the 200-ft. level. The vein material is largely calcite with more or less quartz and a varying percentage of andesite from the walls. The amount of andesite is much greater at the 200-ft. level and 300-ft. level than at greater depth. Driving has been started within the last few days, on the 565-ft. level.

Kingman, June 7.

CALIFORNIA

The mines and mineral resources of Imperial and San Diego counties are discussed in a bulletin issued by the State Mining Bureau. It contains 113 pages with illustrations, and was prepared by Frederick J. H. Merrill. Imperial county has no great variety of minerals, but its deposits of crystalline limestone and clay promise a great supply of building material. Its output of metals may be important in the near future. The gold deposits are in the southeast corner. They are in the northwest extension of the gold belt of the Altar district of Sonora, Mexico. In the Cargo Muchacho range are the Golden Cross and American Girl mines. An extensive plant is on the former. The latter is treating about 75 tons per day. Placer ground occurs in the Picacho district. The principal deposit of marble occurs at Coyote mountain. The gypsum deposit covers about 800 acres in the northwest edge of the Fish Creek mountains. Other minerals of this county are discussed.—— San Diego county has an area of 4221 square miles. The physiography is diversified. Parallel ranges of granite have a southeast trend. Gold has been found in many districts of the county. The main area extends south 45 miles from the Montezuma district, east of Warner's, to the Mexican boundary. The focus of mineralization appears to have been near Julian and Banner. Districts are discussed in the following geographic order; northern border, Montezuma or Rice, Grapevine, Mesa Grande, Escondido Ballena, Julian, Granite Mountain, Oriflamme, Stonewall, Boulder Creek, Deer Park, Pine Valley, Descanso, Dulzura, and Mexican Border. The Julian area has a large past production. Considerable space is devoted to building stone, clay, gems, and the occurrence of other metals.

Calaveras County

(Special Correspondence.)—E. J. Carter, for many years with F. A. Heinze in the Coeur d'Alene, Idaho, and J. S. Rear, of British Columbia, have bonded the Columbia mine, between the Utica and Melones mines, near Angels. They are increasing the capacity of their mill, installing Chilean mill, compressor, motors, and hoist. The plant eventually is to treat 500 tons per day. A wide orebody occurs in the mine.

Angels, June 7.

Kern County

In the case of Mrs. Ella de Pauw, former wife of John Singleton, who wished W. Chapman deposed as executor of the Singleton estate, and her present husband, Cornelius de Pauw, placed in control of the Yellow Aster property, the Superior Court of Ventura county would not allow it.

Nevada County

Two teams from this county will enter the first-aid and rescue contests to be held at the Exposition in September.

San Francisco County

The U. S. Bureau of Mines calls attention of miners to the mine in the Palace of Mines and Metallurgy at the Exposition. This was described in the PRESS of May 1. It is an instructive exhibit. A mine-rescue station is in full working order. Mining men may receive first-aid instruction free from 9 to 11 a.m. Rescue classes are held in the afternoon. Six classes would cover the course of training. E. Steidle is in charge of the department.

Shasta County

Two furnaces have been blown-in at the Noble Electric Steel Co.'s plant at Heroult. Ferro-manganese will be produced. A mine near Ukiah, Mendocino county, is supplying manganese ore.—— Fire at Kennett last week burned about $35,000 worth of buildings.

Sonoma County

It is reported that the Great Eastern quicksilver mine near Guerneville is to be re-opened in charge of F. P. Thomas. It has not been worked since 1906.

Trinity County

The Carrville district is reported to be very active.——The mill at the Strode mine is working continuously.——Work is to be resumed at the Bell mine and mill.——The Trinity Development Co. is diamond-drilling placer ground along Coffee creek and the Trinity river.——The Alta Bert dredge is working on adjacent ground near Trinity Center.——Hydraulicking has been resumed at the Schlonberg claims, 20 miles from Carrville. Snow and ice interfere with regular work.——At the Lagrange mine, 10 sluice-boxes were washed away by the heavy rain. There is plenty of water for the season.

11-CU. FT. BOAT OF THE TRINITY GOLD DREDGING CO. ON TRINITY RIVER, NEAR MOUTH OF JENNINGS GULCH.

Tuolumne County

(Special Correspondence.)—The Jamestown mining district is more active than in many years past. Properties that have been dormant for years will ship ore this season. It is estimated that the production for 1915 will be a record. California as well as Eastern capital is being spent freely in this region. Reports of mining engineers are generally favorable.

Within the past few weeks there has resulted, with the reopening of the old Santa Ysabel Mining & Milling Co.'s property at Stent and Quartz, a development that is worthy of favorable comment. The claims are being operated by the Nyman Consolidated Mines Co., recently organized under the laws of California. Ore extraction has begun from the Knox and Boyle vein on the 300, 400, and 600-ft. levels. It is proposed to open two other large orebodies in the next month or so on the Miller and Holmes claim, and on the Nyman claims. The property, including more than 100 acres, is situated two miles south of Jamestown. The five claims have produced over $1,500,000. The new owners of the property have been enabled to take advantage of considerable development done in the past, and are proceeding in accordance with the recommendations furnished in a report by Chas. E. Shafer and F. G. Mudgett. Mr. Shafer was formerly manager of the Harvard mines at Jamestown, and Mr. Mudgett has been examining the mines and conditions in the Jamestown district for the past several years. Recent assays show a good average value from a large available tonnage of ore. The property is fully

equipped with modern machinery, and has a 40-stamp mill. Ten stamps are working two shifts. Control of the property is vested in a company directed by A. L. Trowbridge, C. E. Shafer, R. W. Barrett, D. H. Duncanson, and F. G. Mudgett.

Jamestown, June 2.

COLORADO

Clear Creek County

Slime concentration by flotation has been successfully tried at the Hudson at Idaho Springs. As a result a flotation plant is to be installed. S. P. Warren is in charge.

Ouray County

In April the Camp Bird mill treated 2432 tons of ore. The estimated profit was $40,320. A report for the quarter ended March 31 has been issued. Development amounted to 629 ft. There are 18,288 tons of ore broken in stopes. Work at No. 5½, 6, 7, and 8 levels disclosed nothing of importance. No. 3 shaft was sunk 102 ft. to 1006 ft. below the collar. A station was cut at No. 9 for the pumps. These will lift water 1000 ft. The maximum capacity is 700 gal. per minute. Installation was expected to be finished late in May. Cross-cutting to the vein would then be resumed. The mill treated 7963 tons. Bullion and concentrate realized $252,063. Working expenses totaled $93,046. The profit, including $72,000 from Santa Gertrudis, Mexico, was $216,000.

IDAHO

Lemhi County

The Pittsburg-Idaho company at Gilmore is to increase its shipments to 1750 tons of ore per month. Development at 400, 500, and 600 ft. has opened over 20,000 tons of high-grade ore.

Shoshone County (Coeur d'Alene)

Work was resumed at the National copper mine at Mullan on May 31. A shaft is to be sunk on the lode. Diamond-drilling cut ore 130 ft. below the main lower adit. The property has been idle since last year.——The Montana-Idaho Copper Co. has issued a report regarding the Monitor mine. Since the summer of 1910, when forest fires destroyed the surface plant, the mine has not been operated. The main shaft collapsed and filled with water. A railroad has been constructed through the district, making transport cheaper. To raise funds, this company was formed with enough capital to buy the Monitor and other properties along the course of the proposed adit, and for their development. The capital is 6000 shares at $100 each. Buildings have been erected, also a small water-power plant, compressor, and the adit was in about 300 ft. late in May. At a depth of about 1800 ft. the Monitor vein should be cut.——It is rumored that a deadlock exists between the American Smelting & Refining Co. and the Hercules company over the latter's ore contract. As a result the mine and mill have been closed.——Work has been resumed at the Amador mine. A 100-ton mill is to be built. S. L. Shonts and Oscar Nordquist, of Wallace, are in control.——There is renewed activity on Pine creek. Promising mines are the Douglas, Constitution, Carbonate, Northern Light, Highland Surprise, and the Antimony-Silver.

MICHIGAN

Houghton County (The Copper Country)

It is estimated that the May copper output of the region totaled approximately 25,000,000 lb. This does not include the White Pine yield.——The Allouez production is to be raised to 1,000,000 lb. per month.——The Franklin is increasing its extraction of ore from the Allouez lode.——More conical-mills are to be added to the Champion mill. An 800-hp. turbo-generator is also to be installed.——Work has been resumed at the Winona. The output of ore will be about 600 tons per day, stamped in its own mill.——The Tamarack, Jr., shaft-house and rock-crusher were burned on June 2, probably by an incendiary. The mine was closed 15 years ago.

MONTANA

Fergus County

A cyanide plant is to be erected at the Spotted Horse mine at Maiden in the Judith mountains. Lessees have opened a good deal of ore down to 585 ft.——A $150,000 tipple and washer is being constructed by the Cottonwood Coal Co. near Windham. The Great Northern railway purchases the output of coal. Over 190 men are employed.

Jefferson County

During April the Boston & Montana Development Co. at Elkhorn advanced its adit 4½ ft. per day. It is in 1875 ft. Small veins have been cut. The formation is getting softer and is heavily mineralized. One vein should be cut at 2000 feet.

Lewis and Clark County

Unusual activity prevails in the Marysville district near Helena, including the Scratch Gravel hills, Unionville, and Blue Cloud. Work at the Shannon, Bald Butte, Franklin, Purnell, Whitlatch Union, Morning Star, and others is encouraging. The Helena Mining Bureau continues its activities.

Silverbow County

At 2500 ft. in the Davis-Daly mine, 10 ft. of 7% copper ore has been cut. It also contains a good deal of silver. A 1300-cu. ft. capacity compressor is being installed.——At 3000 ft. in the North Butte the Edith May vein is opening well.

NEVADA

According to F. M. Manson, of the Western Ore Purchasing Co., Nevada mines and mining districts are more lively than they have been in years, and more ore is being shipped than for a long time.

Douglas County

(Special Correspondence.)—A leaching plant is being erected at the Ruby Hill Gold & Copper Co.'s mine in the Pinenut district. Well-known Nevada men are in control. M. R. McColloms is in charge.

Gardnerville, June 1.

Esmeralda County

(Special Correspondence.)—Tests are being made on an elaborate scale to devise a process to treat profitably the low-grade ore, down to $5 per ton, of the Goldfield district. These experiments are said to be encouraging. Metallurgists will arrive here shortly from the East to conduct tests on a larger scale. The discovery of such a process would be of vital importance to Goldfield, as there is available a large tonnage of gold-silver-copper ore, containing from $5 to $12 per ton, in the Mohawk, Laguna, Red Top, Clermont, and Grizzly Bear mines of the Goldfield Consolidated, as well as in the Atlanta, Jumbo Extension, and other ground. Tests with the refractory ores of the district by oil-flotation have not so far been entirely satisfactory.

Since it has been determined that the lodes of the district penetrate the shale, after extending for considerable distances along the surface of the shale, interest will naturally be directed to the conditions existing at the contact of the shale and granite and the possibility that the lodes may be found to penetrate the latter.

Development work is supplying all ore shipped by the Jumbo Extension company. Shipments to the Western Ore Purchasing Co.'s sampler are maintained at 45 tons per day, the value being $60 to $70 per ton.

Reports that an apex suit was to be brought against the Atlanta by the Florence company are denied on the highest authority. Walter E. Wiley, who lately represented the Booth company in its apex controversy with the Jumbo Extension and other companies, has been here during the past week. It is reported that he was engaged in preparing a report upon which to base a side-line agreement between the two companies.

In the Gold Mountain district, 35 miles south of Goldfield,

work will be started by the Nevada Co-operative Mines Co. on the property acquired from the Nevada Empress company.

The Pioneer Consolidated Mines Co. has resumed operations on its property in the Pioneer district, 55 miles south of Goldfield.

Goldfield, June 7.

The estimated production of the Goldfield Consolidated Mines Co. in May is as follows:

Ore mined, tons	32,277
Gross extraction	$334,000
Operating expense	174,000
Net realization	160,000

Between May 15 and June 1 the Atlanta Mines Co. shipped 550 tons of $20 to $30 ore to the Western Ore Purchasing Co. ——One car of ore per day is being shipped from the Jumbo Extension. The shoot at 880 ft. is 350 ft. long, averaging $40 per ton. The drift has been stopped in low-grade ore.——Encouraging results are being obtained at 700 and 800 ft. in the Oro.——A cross-cut from the winze below 500 ft. in the Sandstorm Kendall has cut $44 ore.

An examination of the Southwestern mine, formerly the Great Western, at Hornsilver, 28 miles from Goldfield, shows that $246,000 worth of silver-gold ore exists. Work has been done to a depth of 445 ft. A 50-ton mill is recommended.

Humboldt County

(Special Correspondence.)—Willard is having the usual ups and downs of a new gold centre. The past 30 days have seen the settling of disputes of claim-boundaries and adjusting differences of ownership.——There are about 20 sets of lessees at work; seven are shipping ore. Practically all have free gold as shown by panning. Ed. Orr got an assay of $984.50 from a quartz seam, and he also got a sample of $7 from across 13 ft. of his lode.——Jack Borland has 450 sacks of shipping ore. He has 18 in. of $120 ore that shows coarse free gold.——Lessees at the Sheepherder's Dream continue to bring in 'picture rock.' ——High-grade ore has been opened in the Venture claim, which is worked under lease and bond by Denver people. This discovery extends the area of the district east about 3000 ft. ——The Hunter-Borland adit is in 60 ft. in shipping ore. Their bin is completed, as well as the wagon-road up the gulch.—— The Oddie lease is sinking the shaft with two shifts. It will cut the vein on its dip.——The nearness of the railroad makes it possible to ship ore as low as $15 per ton at a profit. The telephone-line is now working. The Nevada Valleys Power Co. has surveyed a line to here, and promises to install a transformer in the near future.

Lovelock, June 7.

(Special Correspondence.)—There is not much to write about in the new Willard district. There are a number of good surface indications. They seem to be little gash-veins, rich near the top, but with little promise for depth. Other observers seem to see much more. For a while lessees will probably make some money.

Willard, May 29.

Last week block No. 2 of the Honey Bee was acquired by E. Malley, ex-Governor Oddie, G. Cole, and Jim Butler. The shaft is being sunk and should cut the vein at 100 ft.——The Honey Bee company is driving a cross-cut adit to prospect the ground. ——The Sargent lease is down 35 ft.——Good headway is being made in the Finland claims.——The town is quiet. Business people are optimistic.

The above correspondence and news gives three views on the Willard district. So far the deposits seem to be small.

A clean-up from a six days' run at the Seven Troughs Coalition mill yielded $5300. A dividend of 2½c. per share, equal to $37,500, was paid last week.

Lyon County

The Mason Valley company's smelter at Thompson may be blown-in on June 15.——The Nevada-Douglas, Bluestone, and Western Nevada mines are working full time. On May 29, 1913, F. May was injured at the Nevada-Douglas. He is now suing the company for $40,000.

Nye County

Mines at Tonopah last week produced 10,645 tons of ore valued at $217,570.——At 1350 ft. in the Extension the Murray vein was cut last week.——The Jim Butler company has purchased the Ophir King claim east and south of its property. ——Two sets of lessees are working in an old part of the Montana.

White Pine County

(Special Correspondence.)—The Nevada Consolidated is working at full capacity. Power shortage prevents a larger output. The flotation-agitators require a large amount of

EASTERN NEVADA AND WESTERN UTAH.

electric power. This limits the capacity of the concentrator, which is driven by motors. The new engines will remedy this. It will be two months before underground mining at the Ruth mine can be commenced. A small force is preparing to mine by the system used at the Ray mine, Arizona. There are a number of lessees working in the district, and at other places in the county. There is more mining activity than for several years.

From reliable information it appears that the new district of Volcano, 15 miles northeast of Tonopah, will make good. At two points, two miles apart, lessees are sacking ore of a minimum grade of $240 per ton, mostly gold. It is thought that with depth silver will predominate.

Ely, May 28.

UTAH

The increased price of lead means over $200,000 per month additional earnings to Utah lead-silver producers. These mines yield about 7500 tons of metal per month. The important districts are Bingham, Park City, Tintic, and Beaver.

Coal production of this state in 1914 totaled 3,103,036 short tons worth $4,935,454, according to the U. S. Geological Survey. This was a decrease of 141,792 tons, due to less business on the railroads and at smelters. There were 4112 men employed in coal mines. They averaged 3.6 tons each per working day.

Beaver County

The report of the Cedar Talisman Consolidated Mines Co. for the year ended March 31, 1915, shows that the revenue totaled $14,964. Expenses were $10,720. Development has opened a large tonnage of lead and zinc ores. Four cars of the latter netted $4000.

Piute County

As soon as the Mineral Products Co. can obtain right-of-way

for the tramway from Marysvale to the alunite deposit at Edna crater, the mineral will be developed. Over $100,000 has been spent by the company. The alunite contains up to 13% potash. Bauxite also occurs there. H. H. MacDowell is vice-president.

SALT LAKE COUNTY

Ore is now being hauled from the Alta Con. mine to Wasatch.——Eight feet per day is being driven in the cross-cut of the Emma copper mine. Small veins have been cut, and a good development is expected at any time.——The Albion company has started cross-cutting for the Greeley fissure at the quartzite-limestone contact. Part of the Quincy adit is being re-timbered.——The South Hecla has commenced shipping 15% lead ore.

SUMMIT COUNTY

In Bulletin 581-E of the U. S. Geological Survey, Carroll H. Wegemann describes the Coalville coalfield. This district is 30 miles northeast of Salt Lake City, near Coalville. High-grade bituminous coal has been mined for over 50 years. Three beds are worked at present. They are involved in extensive rock folding, and are broken by faults of considerable magnitude. The operating mines are large and well equipped.

A Callow flotation plant is to be installed in the Silver King Coalition mill at Park City. The present concentrating plant is treating 250 tons per day. This will be increased to 600 tons with the new equipment.

WASHINGTON COUNTY

About 85 men are now employed in the Goldstrike district. The new road from Modena, on the Salt Lake Route, is complete. Rich ore has been cut in the Sentor claims of the Goldstrike Con. company.

CANADA

BRITISH COLUMBIA

During the week ended May 29 the Trail smelter received 6941 tons of ore, including some from Washington mines. For the year the total is 177,035 tons.——A lease has been taken on the Blue Bird at Rossland by E. L. Tate, of Spokane. The mine promises to develop well.——The Tonopah Belmont company, of Nevada, has arranged for an extension of its option on the gold mine at Surf inlet. A lower adit has not yet cut the shoot opened above.——The Quatsino Copper Co. has been formed with a capital of 1,000,000 $5 shares. It will develop a property an Vancouver island.

ONTARIO

The report of the International Nickel Co. for the year ended March 31, 1915, contains the following: the net income was $7,230,760, against $6,566,786 in 1913. Out of the balance of $5,598,071, dividends amounting to $5,288,694 were paid. The year commenced with a surplus of $5,006,247, and ended with $5,315,624. When the War started the company's business was considerably affected, but since the end of 1914 there has been an increasing demand for the product.

MEXICO

HIDALGO

In April the Santa Gertrudis mill treated 13,228 tons, yielding a profit of $27,360.

PERU

(Special Correspondence.)—La Cotabambas Auraria is the largest gold producer in Peru. It yields about $25,000 per month. This is recovered from amalgamation plates of a 10-stamp mill. A small cyanide leaching plant consists of 8 tanks, 12 ft. diameter by 4 ft. high. It treats about 12 tons per day. The company has ordered a Dorr classifier, 2 Huntington mills for regrinding, 2 Dorr thickeners, 2 Parral tanks, rotary-blower, stock-tanks, pumps, etc., necessary to treat 20 tons per day, by agitation. In case the extraction obtained by the new installation is equal to that obtained in preliminary tests, the company will immediately order additional machinery requisite to treat 100 tons per day.

Cuzco, May 1.

PERSONAL

W. MOTHERWELL is here from Miami.

O. B. PERRY is at the St. Francis hotel.

H. W. HARDINGE was at Juneau recently.

JOHN B. FARISH is due at Denver from New York.

BEN. S. REVETT has returned hither from Colorado.

A. C. LAWSON has gone to Alaska and will return in July.

JOHN T. REID will return from New York to Nevada about June 15.

F. SATCHELL CLARKE, of Vancouver, B. C., was here during the week.

C. M. HERON is examining placer ground along the Sacramento river.

WILLIAM MACKENZIE has returned to Santa Paula, California, from Nevada.

T. B. CROWE, S. J. CONNOLLY, and J. M. TAYLOR, of Cripple Creek, are at the Plaza hotel.

H. FOSTER BAIN has been elected a member of the Institution of Mining and Metallurgy, London.

W. A. ESTABROOK will be retained as superintendent of concentrator at the Washoe plant, Montana.

JOHN D. RYAN has been elected president of the Anaconda Copper Co., B. B. THAYER becoming first vice-president.

I. NAGAZUMI, of the mining department of the Imperial University at Kyushu, Japan, is in Montana. He has also been in Utah.

MAX ROESLER is the first recipient of the Emmons Memorial Fellowship. Since February he has been instructor in geology at Yale.

M. E. PURCELL, superintendent of the Consolidated Mining & Smelting Co.'s Centre Star-War Eagle group of mines at Rossland, B. C., is expected in San Francisco.

E. S. BARDWELL, who has been in charge of the Anaconda company's exhibit at the Exposition, has returned to the Boston & Montana reduction works at Great Falls.

RALPH HAYDEN, formerly superintendent of slime plants, has been appointed superintendent of the re-grinding and flotation plants at the Washoe Reduction Works, Anaconda.

FERDINAND MCCANN has been examining the mill at La Cotabambas Auraria property, Peru. He is in charge of erection of new plant, and will be there till about the end of this year.

A. E. WIGGIN, formerly concentration engineer, has been appointed superintendent of concentration and will have charge of all concentrating operations of the Anaconda company in Montana.

C. R. WRAITH, who was formerly employed as a chemist in the laboratory at the Washoe Reduction Works, has been placed in charge of the Anaconda company's exhibit at the Exposition.

C. E. WEED has been appointed underground mining superintendent at the Lake mine. Mr. Weed is a graduate of the Michigan College of Mines and for several years has been mining superintendent at the Victoria mine.

Obituary

PATRICK CLARK, well known in the Coeur d'Alene, Idaho, died of heart-failure at Spokane on June 7.

JOSEPH WEISSBEIN was burned to death in a house at the Pittsburg mine, Nevada City, on June 5. Foul play is suspected.

W. M. JOHNSTON died in Chicago on May 13, aged 69. He was president of the mining machinery firm of W. M. Johnston & Co., who have been in business in Chicago for the past quarter of a century. As a mining man he was well known throughout the western states, Alaska, and Mexico.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets

Metal Prices

San Francisco, June 10.

Antimony	35 —35¾
Electrolytic copper	19¼—19½
Pig lead	6.25— 7.20
Quicksilver (flask)	$90.00
Spelter	25 —25¼
Tin	39½—41
Zinc-dust, 100-kg. zinc-lined cases	27½

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, June 10.—Domestic buying of copper is active; lead is strong with recent advances; excitement in spelter is diminishing, but the market is strong.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending

After showing signs of weakness, silver is slowly increasing in price. On June 5 about 430,000 oz. left San Francisco for China. Writing May 20, Samuel Montagu & Co. states that a burst of activity from the Indian Bazaars coming on a somewhat depleted market, caused an upward movement. For a long time they had not been keen on silver speculation. The governing idea seems to be that a substantial advance in price is likely to accompany the cessation of war.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

May	13.97	18.71	Nov.	11.75	....
June	13 60	....	Dec.	12.75	....

Exports during the week ended May 22 totaled 15,183,075 lb., valued at $2,614,010. France took 6,394,056 lb., England, 3,989,690 lb.; Italy, 2,804,214 lb.; Denmark, 985,620 lb.; and Russia, 448,489 pounds.

The Amalgamated Copper Co. was dissolved on June 9. It reports as follows for the 16 months ended April 30, 1915: Income and dividends, $8,647,012; interest, $1,034,404; taxes, $80,387; office, $184,932; net income, $7,347,288; and dividends paid (five), $6,924,955. The year 1914 started with a balance of $23,639,139. The period ended with $21,753,153. Total assets are $177,577,835. Profits to date total $113,032,300. Of this, $91,279,147 was paid in dividends.

Production of the Lake Superior mines in May was about 25,500,000 lb., worth $5,100,000.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
May 13	75.00	May 27	75.00
" 20	75.00	June 2	80.00
		" 9	90.00

Monthly averages.

	1914.	1915.		1914.	1915.
Jan.	39.25	51.90	July	37.50	....
Feb.	39.00	60.00	Aug.	80.00	....
Mch.	39 00	78.00	Sept.	76.25	....
Apr.	38.90	77.50	Oct.	53.00	....
May	39 00	75.00	Nov.	55.00	....
June	38.60	....	Dec.	53.10	....

Stocks of quicksilver are reported to be very low. The entrance of Italy into the War may affect the market. That country produces about 29,000 flasks per year, and it is certain that exports cannot be made from there. The Nevada Cinnabar Co., Ione, on May 29 shipped 310 flasks East. The condensers are to be cleaned out, and from 600 to 1000 flasks is expected.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

Date.		Average week ending

Letters from our correspondents in Missouri and Wisconsin appear in this issue, and reflect the local situation of the zinc industry. The Missouri-Kansas-Oklahoma region is excited. Concentrate, 60% metal, rose to $112 per ton. The output of blende, calamine, and lead for the week ended June 6 was valued at $762,320, a record. For the year it totals $9,032,798. Smelting companies at Bartlesville raised wages 15% on June 4. Some miners at Joplin struck on June 6, demanding higher wages. Machine-men received an increase from $3.75 to $4.25 per shift. Many companies advanced wages voluntarily.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1914.	1915.		1914.	1915

On June 9 tin was 40c. per pound.

Eastern Metal Market

New York, June 4.

All of the metals are strong and show a tendency to advance. Since May 25 a series of advances in lead totaled $20 per ton and brought the price per pound to 5.20c. A depletion of stocks due to the War demand is the best explanation obtainable. Spelter is higher than ever and its price, as one consumer has expressed it, seems to be whatever the holder wants to ask. Copper is firmer, and more activity has prevailed. Spot tin is plentiful. The May deliveries were next to the record as regards quantity.

Makers of brass valves, fittings, and supplies, who are large consumers of the metals, seen at the convention of the American Supply and Machinery Manufacturers' Association at Philadelphia this week, expressed the opinion that the prices of spelter and antimony have passed the bounds of reason. Some of them have been hard hit, while others, for instance a maker of brass valves, have not been seriously affected, inasmuch as they had ample stocks. A maker of anti-friction metal, of which spelter is the base, said he was not only asking for extension of time in which to make deliveries to automobile manufacturers, but said the size of the deliveries were far under normal. This man looks for 25c. copper. With regard to spelter, one consumer, who gives its price range June 3 as 24.20 to 25.20c., says he understands that the United States government has obtained options on a good part of the production. There had been rumors that the Government was negotiating with one or two large producers.

COPPER

The market has continued quiet, although a little increased interest on the part of domestic consumers has been shown in the last two days, and prices have stiffened. From 18.50c. cash, New York, quotations for electrolytic have advanced to 18.87½ to 19c. cash, on prompt shipments, these being the quotations June 4. A few sales at the higher price are reported. There is less re-sale metal offered. A feeling on the part of some consumers is that prices are destined to go higher, and those who have not covered their requirements are making inquiry. The exports in May totaled 28,884 tons, against 32,077 tons in the same month last year, a fairly good showing, considering all conditions. Of the May exports, 13,416 tons went to France, 8643 tons to the United Kingdom, 4261 tons to Italy, 1449 tons to Sweden, and smaller shipments to other countries. The exports since January 1, exclusive of those at Southern and Pacific ports for May, amounted to 119,546 tons, against 184,312 tons in the same period of 1914, a decrease of about 65,000 tons. Lake prices range from 19 to 23c., with the higher grades nominal, inasmuch as they cannot be obtained for early delivery.

LEAD

The daily advances announced by the American Smelting & Refining Co. in the past few days have caused a swerving of interest in the lead market. The company's quotation is for 50-ton lots. The quotation was advanced on May 27 from 4.30c., New York, to 4.40c. Then followed these changes: 28th to 4.50c., 29th to 4.75c., June 1 to 4.90c. And June 3 the predicted rise to 5c. was announced. On June 4 the largest made its price 5.20c. per pound. The early advances served to arouse interest, and buyers followed the market to 4.90c. and beyond. In the week, more business was done than at any time in two months. An authority in the trade is of the opinion that the War demand has finally depleted the reserve-stocks of the metal. The independent producers, in particular, are believed to be well sold-up ahead. Meanwhile there have been some large inquiries on which the independent producers apparently could not quote.

SPELTER

The market has continued to advance in leaps and bounds, and, so far as prices go, has reached a most uncertain stage. Quotations for prompt shipments range all the way from 26.50 to 27.50c. This week some re-sale metal has appeared, and it is said that some of the offerings are made by consumers who have found substitutes, and are seeking to turn their spelter stocks into cash. Offerings are said to have been made also by some of the smaller manufacturers of galvanized sheets who have withdrawn their ordinary product from the market. There has followed, in consequence, an increased production of black sheets and the prices of these are weaker. The base price of sheet-zinc was advanced June 1 to 26c. f.o.b. mill. Makers of galvanized pipe this week advanced their prices $10 per ton. With the scarcity of spelter and the high prices the volume of business, of course, had gradually been growing less, but the scarcity is the chief restriction to activity at this time. As matters now stand, consumers are in reality bidding the market up on themselves. Sales into next year have been made at 17c. The makers of sheet-brass continue to decline to accept business, and the withdrawal of base prices by the American Brass Co. is still effective. Outside of the War demand there is but little doing in the way of new business with the brass mills.

TIN

Contrary to the trend of other metals, tin has pursued a course of weakness, although greater strength developed today and the quotation (June 4) is 38.12½c. A peculiar feature of the market is that futures have been higher, relatively than nearby deliveries, which may be accounted for by the element of uncertainty for the future which is now felt in all the markets. Some good business has been done in the past few days, both spot and future deliveries being taken, while June and July shipment from the East were in favor. A point in the situation which consumers do not like is that future deliveries are not guaranteed. August delivery has sold at 37c. The statistics for May are interesting, inasmuch as the deliveries into consumption amounted to 5600 tons, the second largest month on record. In the month there was a decrease of 1139 tons in the total visible supply. The total visible on June 1 amounted to 14,646 tons, more than half of which is en route to, or in stock in, this country. There is now afloat 5640 tons. In the first five months of this year deliveries into domestic consumption totaled 17,675 tons, a decrease of 1775 tons compared with the same period last year. On June 3 the steamer *Westward Ho* arrived at New York with 475 tons from Penang, 50 tons from Singapore, and 220 tons from Batavia, thereby adding another large arrival to an already notable list.

ANTIMONY

There is no feature to report, except that the market remains firm, with offerings few. Chinese and Japanese are quoted at 35 to 38 cents.

ALUMINUM

There is a good demand, with quotations at 27 to 28c. There is a good deal of looking around for sheets, which are nominal at 32 to 34 cents.

Exports of metals, June 1 to 5, were as follows: copper, 3725; lead, 1638; and spelter, 135 tons.

Control of the spelter market was discussed by Paul A. Ewert, of Joplin, Missouri, before zinc-ore producers at Webb City recently. There are approximately 120,000 retorts in the United States. Of these, 87,000 are owned or controlled by what is known as the 'Big Five' group of smelting companies. Therefore he said they determine the price of the metal produced.

COMPANY REPORTS

RIO TINTO COPPER COMPANY, LTD.

During 1914 this English company operating in Spain only sold 48,193,600 lb. of copper, against 81,356,800 lb. in 1913. After paying all expenses and adding £185,872 from the previous year, there were £923,251 available, compared with £1,913,769. From a net balance of £899,399, two preference dividends absorbed £81,250. A distribution of 35 shillings ($8.40) per share on the ordinary shares amounted to £656,250. The surplus carried forward was £162,439. Operations are now at the rate of four days per week.

ISLE ROYALE COPPER COMPANY

This Michigan company was unfortunate in 1914, in that it suffered from the effects of the miners' strike in 1913, the copper market, and the loss of its mill by fire at the end of 1914. The plant is now being rebuilt. Results were as follows:

	1914.	1913.	1912.
'Rock' stamped, tons	474,349	314,679	531,105
Copper sold, pounds	6,601,235	3,870,974	7,782,078
Price received, cents per lb..	13.16	15.29	16.66
Cost, cents per lb.....	13.05	18.81	11.89
Total income .....$	885,888	$ 649,946	$1,395,636
Operating profit	38,442	128,313	430,045
Dividend	.....	150,000	.....
Surplus at end of year	199,815	175,441	557,743

COPPER RANGE CONSOLIDATED COMPANY

This Michigan company controls the Baltic, Champion, and Trimountain mines and works. Owing to the copper market, the properties were operated at 50% capacity from early in August 1914 to January 4, 1915. They are now at full production. The past three years compare as follows:

	1914.	1913.	1912.
Ore crushed, tons.....	1,216,538	984,287	1,784,402
Copper produced, pounds..	27,857,457	24,852,026	37,584,647
Revenue .....$	3,726,389	$3,707,091	$6,084,202
Operating profit	871,049	1,054,511	2,422,364
Deductions	412,395	345,698	709,802
Net income	494,600	490,533	1,692,566

Only half of the Champion copper output is included in the profit. The actual production on which the Copper Range company derived profit was 19,953,854 lb. Assets exceed liabilities by $1,105,226.

BROKEN HILL SOUTH SILVER MINING COMPANY

The report of this company for the second half of 1914 affords interesting reading, on account of the effect of the War on this lead-silver-zinc district of Australia. The manager, W. E. Wainwright, reported as follows:

The stoppage amounted to 56 days. Development was considerably curtailed, and totaled 3549 ft., including 698 ft. of diamond-drilling. Ore raised amounted to 111,891 tons, compared with 172,421 tons, averaging 15.3% lead, 7.1 oz. silver, and 14.2% zinc. Filling dumped underground totaled 25,698 tons. The 825, 970, 1070, and 1170-ft. levels produced 10.8, 21.8, 37.3, and 19.4% of the ore mined. The 1270-ft. level yielded 252 tons, and a wide body of ore has been cut at this depth. At 1470 ft. a pump cistern is being excavated near No. 1 shaft. Ore reserves remain at about 3,350,000 tons.

The mill treated 112,750 tons of ore, yielding 20,375 tons of concentrate, assaying 64.9% lead, 21.6 oz. silver, and 8.3% zinc, and 69,943 tons of zinc tailing averaging 3.1% lead, 3.3 oz. silver, and 16.9% zinc. Metal content of the lead concentrate was 13,229 tons lead, 440,817 oz. silver, and 1696 tons zinc, against 19,679, 632,010, and 2034 respectively in the previous half year.

Costs were as follows: mining, $3.11; filling stopes, 20c., development, 59c.; and treatment, $1, a total of $4.90 per ton, a reduction of 22 cents. The revenue from mill products was £185,468, of which £69,252 was profit, against £349,095 and £163,480 respectively in the former period. The balance at June 30 was £143,682, and at December 31, £232,648.

The rainfall was 5.28 in., and water consumed amounted to 26,675,000 gallons.

UNITED STATES SMELTING, REFINING & MINING COMPANY

According to the president of this company, W. G. Sharp, the year 1914 was one of difficulty in many respects. The European war created a business disturbance which affected materially all departments of the company's activities. These included the Mammoth Copper mine in California, the Utah company, producing coal, and the silver properties at Pachuca, Mexico. The staff left the Real del Monte mine and mill in April and returned in September. It has been difficult to get supplies, and the tonnage treated in December was 570 tons per day. At present it is 1400, against a capacity of 2000 tons. It is impossible to forecast future Mexican conditions, but if operations can continue to be conducted on the present scale, the Pachuca properties can be depended on for a substantial contribution to the net earnings during the current year even if silver remains at its present low level of 48c. per ounce. It is a pleasure to note that during all the unsettled conditions in Mexico the properties and employees have always been respected, so that there has never been and property damage or interference with the employees.

Metal output during the past three years was as follows:

	1914.	1913.	1912.
Copper, pounds 17,946,659		20,239,973	21,152,620
Lead, pounds 64,443,260		58,116,504	56,385,769
Silver, ounces	9,936,237	13,089,708	12,059,829
Gold ounces	124,719	148,372	140,183

The average price received for the different metals during the year compared with prices of previous years:

	1914.	1913.	1912.
Copper, cents per pound.....13.404		15.433	16.237
Lead, cents per pound.....	3.827	4.396	4.529
Silver, cents per ounce.....55.564		60.503	61.291

The net profit for the year amounted to $2,265,641, compared with $3,585,586 in 1913. Adding the previous balance of $4,478,842, made $6,744,484 available. Out of this, $1,702,221 was paid in dividends to the preferred shareholders, and $526,671 on common stock, leaving a balance of $4,515,591. Assets include ore and matte, $1,252,012; supplies, $1,461,779; and metal in ore and on hand, $4,472,246, all increases on the previous year.

TAMARACK MINING COMPANY

During five months of 1914 this Michigan company's property was shut down. It is now producing again. The past three years' work is summarized in the following table:

	1914.	1913.	1912.
'Rock' stamped, tons	57,410	227,563	421,385
Refined copper yield, pounds.	1,074,808	4,168,743	7,908,745
Metal sold, pounds	1,074,808	3,852,040	7,298,205
Average price, cents per lb..	12.80	15.45	16.56
Revenue from copper .....$	137,600	$ 642,713	$1,300,238
Cost, cents per pound.....	29.08	16.60	13.15
Loss on operations, including all charges	174,944	48,373	*260,044
Balance of assets	895,993	1,070,938	1,120,861

*Profit.

Work on the re-crushing plant, to treat old tailing in the lake, is well ahead. It is 99 by 240 ft., and will contain 32 Hardinge conical pebble-mills, and 92 Wilfley tables.

BOOK REVIEWS

DIRECT-ACTING STEAM PUMPS. By Frank F. Nickel. McGraw-Hill Book Co., Inc., New York. P. 254. Index. Illustrated. For sale by *Mining and Scientific Press*, San Francisco. Price, $3.

While the development of the centrifugal pump and its generally greater fuel economy has resulted in the displacement of the direct-acting pump in some cases, there remains, nevertheless, a large field of usefulness for the latter type of pump. The present volume, after tracing the historical development of the direct-acting pump, devotes a chapter to the consideration of the factors affecting performance and efficiency. The various types of pumps are then discussed. Pump-end details and steam-end details each have a chapter devoted to them. The selection of a particular type of pump to suit given service conditions is then discussed. Short chapters are devoted to the duty and to the operation and adjustment of direct-acting pumps. The appendix contains data on the friction head when pumping certain kinds of petroleum.

PRACTICAL OIL GEOLOGY. By Dorsey Hager. P. 141. Ill., index. McGraw-Hill Book Co., Inc., New York. For sale by *Mining and Scientific Press*, San Francisco. Price, $2.

For many years the relations between the geologist and the 'practical' oil-man have resembled either armed neutrality or actual warfare. Like most other warfare, this has been caused by misunderstandings on both sides, while the extravagant claims of the extremists in both camps have tended to widen the breach. The present volume partakes more or less of the nature of an attempt by a geologist to extend the olive-branch to those on the opposing side. After discussing the theories of the origin of petroleum, its physical and chemical properties are briefly considered. The elementary facts of structurel geology and stratigraphy are considered and the value to the oil-man of a knowledge of these facts is clearly shown, both as regards the initiation of operations in 'wild-cat' territory and the placing of wells in both 'wild-cat' and proved fields. The book also treats briefly of some of the commoner problems in well-drilling and in maintaining production, and particularly the problem of combatting water. While there are occasional sweeping statements to be found in the book, which might mislead the novice, in general it will be found of value to those interested in the oil industry.

TUNNELING. By Eugene Lauchli. P. 230. Ill., index. McGraw-Hill Book Co., Inc., New York. For sale by *Mining and Scientific Press*, San Francisco. Price, $3.

In few branches of engineering has there been as much progress in the past few years as in tunneling. Improved kinds of machinery for drilling and for the removal of excavated materials have followed rapidly upon each other until records for speed in tunneling are broken almost as often as records for speed of automobiles. With improved machinery has also come more careful study of geological conditions with a view to predicting the formation, pressure, and temperature in long mountain tunnels, making possible the successful completion of tunnel projects that would have been doubtful at least a few years ago. The methods of driving tunnels of small cross-section and also of driving railroad tunnels of moderate length are discussed, but the driving of long tunnels is given the fullest treatment. The methods of removing excavated materials, and of ventilation in long tunnels are carefully considered. So also is the question of rock-pressure as affecting the lining of deeply-overlaid tunnels. Driving tunnels through soft materials by compressed air and by other methods is also considered.

THE EFFECT OF BORON UPON THE MAGNETIC AND OTHER PROPERTIES OF ELECTROLYTIC IRON MELTED IN VACUO. By Trygve D. Yensen. Bulletin 77. P. 19. Illustrated. This bulletin is the second of a series dealing with the magnetic, electrical, mechanical, chemical, and metallurgical properties of iron melted in a vacuum furnace. It was shown in Bulletin 72 that iron of an exceptionally good magnetic quality could be produced in such a furnace. No. 77 gives the results obtained by adding boron to pure iron. Small percentages of boron added are shown to improve the iron slightly, while boron added in sufficient amount to leave a measurable quantity combined with the iron has a decidedly detrimental effect upon the magnetic properties. The crystalline structure of the alloys is shown by means of numerous photographs.

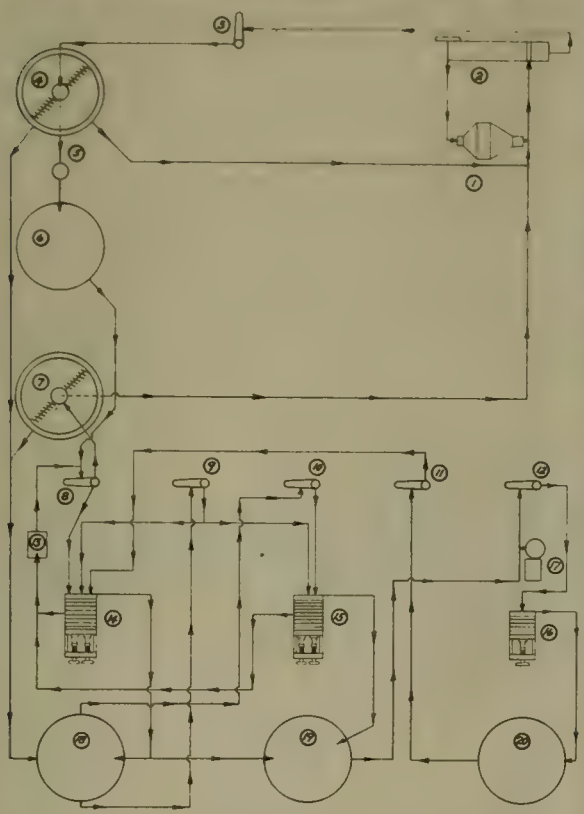
New Machines and Devices

Information based on letters and catalogues from manufacturers

Cyanidation at the Exposition

Excepting a crusher, a complete cyanide plant is at work in the Palace of Mines and Metallurgy at the Exposition. It consists of the following:

The Hardinge Conical Mill Co. operates an 18-in. by 4 ft. 6-in. conical pebble-mill. A Westinghouse 25-hp. motor drives it at 30 r.p.m. by means of flexible coupling and herringbone gear. The usual scoop-feed is attached. In closed-circuit with the



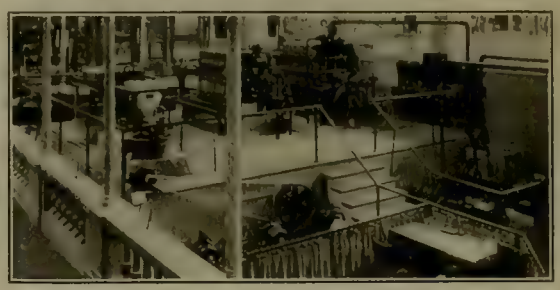
LEGEND

(1) 4½ ft. by 18-in. Hardinge mill. (2) Quarter-size simplex Dorr classifier. (3) 1½-in. single-stage centrifugal pump. (4) 8 by 6-ft. Dorr thickener. (5) No. 2 diaphragm pump. (6) 8 by 6-ft. Dorr agitator. (7) 8 by 6-ft. Dorr thickener. (8) 3-in. single-stage centrifugal slime pump. (9) 2-in. 4-stage centrifugal pump. (10) 2-in. single-stage centrifugal pump. (11) 1-in. 3-stage centrifugal pump. (12) 1-in. 3-stage centrifugal pump. (13) 24 by 30 by 30-in. sump. (14) 10-frame Merrill 3 by 4-ft. sluicing-slime filter-press. (15) 20-frame Merrill 3½ by 3½-ft. sluicing-clarifying filter-press. (16) 10-frame Merrill 36-in. triangular-agitating precipitation-press. (17) Merrill precipitant feeder and grinder. (18) 8 by 4½-ft. unclarified solution tank. (19) 8 by 4½-ft. clarified solution tank. (20) 8 by 4½-ft. barren solution tank.

mill is a ¼-size simplex Dorr classifier. A Byron Jackson 2-in. centrifugal pump lifts pulp to a thickener.

In the Dorr Cyanide Machinery Co.'s part of the installation, Homestake slime is used. There is a 6-ft. deep by 8-ft. diameter ordinary thickener, with diaphragm pump discharge. The thickener has an overload alarm and lifting device. The tank works at one revolution in four minutes. From the thickener the slime goes to a 6 by 8-ft. agitator. This works at 3 r.p.m. Agitator slime is pumped to a Merrill press for filtration. Tailing from the latter is pumped to another thickener for water recovery.

The Merrill Metallurgical Co. has installed an extensive plant. Slime from the agitator mentioned is pumped to a 10-frame, 2½-in. cake (36 by 48-in.) automatically-sluiced slime-press. It has a capacity of 30 tons per day with average pulp. Time occupied in filling is 5 to 7 minutes; washing, 10 to 15 minutes; and discharging, 10 minutes. Reciprocating gear moves the sluicing-pipe for discharging through a maximum of 220°. A clarifying-press takes the thickener (mentioned) overflow. This is a 20-frame, 1-in. cake, 42 by 42-in. automatically-sluiced press. It is a new type of clarifier, and is of 600-ton capacity. The new features are thinner frames, and central motor-driven sluicing-pipe. Clarified solution is next



FILTER-PRESS PLANT.

brought into contact with zinc-dust from a precipitant-feeder and thence to an agitator, pumped through a precipitation-press. The speed of the feeder is regulated by cone pulleys. The precipitant and gold solution meet in the suction pipe between the pump and solution tank. The press has 10 frames, 2 in. wide, and is known as a triangular agitation precipitation filter-press. It has a capacity of 125 tons of solution per day. Five Byron Jackson one to four-stage pumps, direct connected to Westinghouse motors, producing up to 100-lb. pressure for sluicing, are used in the Merrill plant.

Pumps, Crushers, and Steel at the Exposition

In the Palace of Machinery at the Exposition, Harron, Rickard & McCone, of San Francisco, have the largest individual space. Some of the exhibits are as follows:

Two Aldrich mine pumps. Both are similar in design, triplex, valves being very accessible, glands easily packed, adjustable guides, bearings adjustable, cast-steel herringbone gear, occupy little space, and are motor driven, using a flexible coupling. One pump has plungers 7½ by 10 in., 7-in. suction and 8-in. discharge. It is driven by a 75-hp. Westinghouse motor. With a 500-ft. lift it pumps 300 gal. per minute, showing 84% efficiency. The other machine has 2½ by 7-in. plungers. Driven by a 20-hp. General Electric motor it can lift 35 gal. per minute from a depth of 1500 feet.

Sturtevant duplex ring-roll mills are exhibited. The rollers work in a grooved ring. A pressure of 20,000 to 60,000 lb. is attained. The No. 2 duplex weighs 25 tons. Rolls are 10 by 18 in. The ring speed is 64 r.p.m. Seventy to 90 hp. is required. Reducing to 20 mesh the capacity is 15 to 20 tons per hour dry crushing. The Sturtevant 'Newaygo' screen has large ca-

pacity. It will handle 1¼ to 180-mesh product. It will pass 11 tons per hour through 20, and ¾ ton through 100 mesh.

Laboratory and sample crushers are shown. They are easily accessible for cleaning.

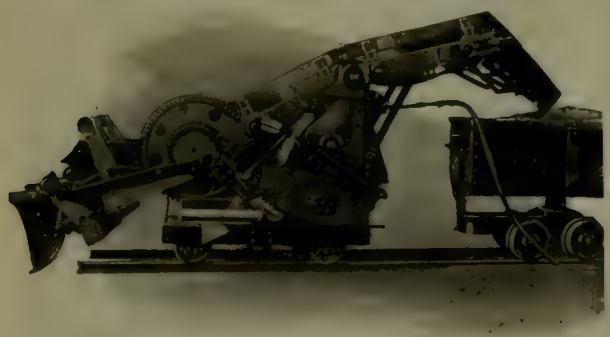
Mining shovels and barrows of best make are on view. A complete 3½-in. Keystone drill is ready for boring to 400 ft. in rock, and 600 ft. in softer ground.

A 300-hp. Cochrane water-feed heater, with a meter guaranteed to 1½%, is of interest to steam users.

The well known Toledo mining steel is displayed, including a beautifully finished collection of hammers, chisels, sections of drill steel, etc., in a case. An interesting exhibit is made by the Carborundum Co. of Niagara Falls. The variety of purposes to which this artificial abrasive is put is surprising.

Underground Shoveling-Machine

The Halby shoveling-machine, manufactured by the Lake Shore Engine Works, Marquette, Michigan, is of a new design. It has been operated successfully for six months in one of the iron mines of northern Michigan. It costs $6.37 to work the



HALBY SHOVELING-MACHINE.

machine an 8-hr. shift. If 200 tons of ore were loaded per shift, the cost is 3.18c. per ton. Hand labor would cost about 10.2c. per ton. In the Judson mine at Alpha the machine works in an 8 by 8-ft. drift. Under normal conditions it fills a two-ton car in 1½ minutes. About 200 cu. ft. of air per minute is required when loading. Gasoline or electricity can also be used. The machine is 15 ft. long (can be shortened to 10 ft.), 5 ft. 4 in. high, and 4 ft. wide, and weighs 7500 lb. It can load 40 tons of heavy ore per hour if necessary.

Commercial Paragraphs

Beaudry motor-driven hammers are described in a 7-page booklet issued by BEAUDRY & CO., INC., Boston.

The SULLIVAN MACHINERY CO. announces that its Juneau, Alaska, office is now in the Forrest building. Burt B. Brewster is in charge.

A new laboratory and office building is being erected by the TROPENAS CONVERTER CO., New York, at Brooklyn. An experimental plant is contemplated.

A 5 by 7-ft. adjustable quick-discharge tube-mill and Wood's type wet-screen of CHALMERS & WILLIAMS make are being installed by the Washita Lead & Zinc Co., Davis, Oklahoma.

Bulletin 221 of the LINK-BELT CO., Chicago, describes the patented circular storage-system for coal, gravel, rock, etc. The system is especially economical for storing over 5000 tons of material.

A new mine telephone has recently been devised and is being placed on the market by L. T. WEISS, of New York. It has been tested in several mines for over a year, one being the property of the International Nickel Co., Ontario.

The TERRY STEAM TURBINE CO., Hartford, Connecticut, an-

office is at St. Paul. The Hawkins-Hamilton Co., Lynchburg, for the territory in Minnesota, North and South Dakota. His office is at St. Paul. Hhe Hawkins-Hamilton Co., Lynchburg, Virginia, represent the firm in this state.

Sprays for cooling condensing water, and washing and cooling air for turbo-generators, are discussed in Bulletins 101 and 151 of the SPRAY ENGINEERING CO., Boston. Sprays and ponds are shown in operation. This is an important subject for steam users.

Arthur Putnam Scott has recently been appointed head of the metallurgical department of the SNYDER ELECTRIC FURNACE CO., of Chicago. He graduated at McGill University, Canada, and has held positions with that institution, the Dominion Iron & Steel Co., and General Electric Company.

The NORDBERG MANUFACTURING CO., Milwaukee, Wisconsin, announces that E. W. Swartwout, formerly of the Chicago office, will be associated after June 1 with Mr. MacLaren in the New York office of the company. Enlarged offices have recently been taken in the new Equitable building, 120 Broadway, New York. The Chicago office will be in charge of John E. Lord.

Lucius F. Hallett, of Denver, owner of the Humboldt mine near Ward, Boulder county, Colorado, is replacing the stamps in the mill with new equipment ordered from the DENVER QUARTZ MILL & CRUSHER CO. This consists of one 8 by 12-in. Denver steel crusher, a No. 1 Denver ore-feeder, and a No. 1 Denver quartz-mill. The Humboldt ore contains iron pyrite and will be treated by amalgamation and concentration.

The steel plant of the INTERNATIONAL HIGH SPEED STEEL CO. at Rockaway, New Jersey, is now rapidly nearing completion. It is expected that it will be in full operation by the latter part of June. The product will be confined to the highest qualities of tool-steels, alloy-steels, high-speed steels of all shapes and sizes, solid octagon and cruciform, and hollow hexagon and round rock-drill steels, for which the company claims it has already achieved an enviable reputation in its famous 'Bulldog' brand.

Concentration of molybdenum ore is difficult. The molybdenite is soft and flaky, and in crushing the ore a great deal is reduced to a fine mesh, and is generally lost. The Ore Concentration Co., of London, states that this difficulty has been overcome in many instances by using the ELMORE process. This consists of a vacuum pan in which pulp, oil, and acid (if necessary) are mixed. The valuable minerals are floated off. Two plants in Norway are giving good results. Ore crushed to 30-mesh gave an average recovery of 91.7 per cent.

In *Catalogue* 8 of the AUTOMATIC STEAM TRAP & SPECIALTY CO., of Detroit, Michigan, the use of the Barton expansion automatic steam-trap is described. The makers claim the following: insures a steady, even distribution of heat; air-hammering is done away with; less fuel and more heat; will increase capacity of any heating plant while decreasing running expense; will overcome the lowering of temperature which naturally ensues as distance from heart of heating plant increases; will expel all water continually condensing in pipes; and is automatic in action, saving an engine and a safeguard against negligence.

The GENERAL ELECTRIC CO. has recently issued illustrated Bulletin No. 41,013, giving a detailed description of that company's direct-current commutating-pole motors, known as type RC. These motors are built with a frame of cast steel of medium weight with symmetrical section. They can be used with sliding-base that maintains a correct driving-alignment, which, with the adjustable shields, permit the installation of the motor on either the floor, wall, or ceiling. These motors may be equipped with covers, rendering them what is known as semi-inclosed, totally inclosed, or self-ventilated. They are wound for 115, 230, and 550 volts direct-current circuits, with permissible voltage range of from 110 to 125, 220, 250, and 500 to 600 volts.

EFFICIENCY OF TAMPING.
By H. C. Cutler 942
Criticism of an earlier article on this topic.

THE SEARCH FOR PLATINUM.
By Howard D. Gray 942
Considerable bodies of low-grade ore have been found at the Rambler mine, Wyoming.

ARTICLES

GRASS VALLEY RE-VISITED—I.
By T. A. Rickard 943
The two principal mines are characterized by continuity of operation and ownership, several smaller properties are doing well. Cast-iron and steel frames have been used in two of the mills, a new type of cam has given better results. Tailing at the Empire mill is passed through a terra-cotta pipe.

OIL EXHIBITS AT THE EXPOSITION 946
An excellent demonstration of the petroleum industry.

KAOLIN. Page.
By Wilson W. Hughes 947
That used in Europe was first brought from the United States, now we import nearly a million dollars worth annually. Kaolin is a hydrous silicate of aluminum, it must be free from impurities for most uses. It is purified by washing, this is combined with mining operations, the washed product is then dried in rather crude apparatus.

ZINC SMELTERS IN UNITED STATES 950
Five companies own 95,000 out of a total of 120,000 retorts in the United States. The ore-producers think this indicates that there is a 'Trust.'

THE TRANSVAAL AT THE EXPOSITION 951
The importance of the Rand as a gold mining district is well brought out by its exhibit.

CYANIDE PLANT AT KUSHIKINO, JAPAN 952
A miniature copy of the Goldfield Consolidated plant has been built at this mine, near Kagoshima, in Kyushu. The ore contains $5.50 gold per ton, and 1,000,000 tons are in reserve.

BEAVER LAKE DISTRICT, SASKATCHEWAN.
By Charles A. Banks 954
The region near Beaver Lake can be reached by railway. The first claims were staked in 1913. The deepest shaft has reached 70 ft., exposing 4 to 5 ft. of ore said to average $16 per ton in gold.

ERUPTIONS OF MT. LASSEN AND TERTIARY ERUPTIONS OF THE SIERRA NEVADA. *By H. W. Turner* 955
The recent eruptions have been of the nature of steam explosions. The hot fragments thrown out have melted the snow and given rise to mud-flows that have extended some distance from the crater.

SMELTING AT GREENWOOD, BRITISH COLUMBIA 956
Per furnace-day 674 tons of charge was smelted, using 13.52% of coke and yielding a 39.7% copper matte. Of the copper present in the ore 77.27% was recovered.

Direct Production of Electrolytic Copper Using G-E Apparatus

The Butte-Duluth Mining Co. is crushing, leaching, filtering and depositing copper electrolytically by a new process.

Ore heretofore considered worthless is used, and 91% of the copper in solution is recovered in 20-minute cycles. The cost of electric power is published at 36 cents per ton.

Electric apparatus furnished by the General Electric Company is used throughout the property and has proved up in every way.

Our engineers will be glad to study your power problems and recommend suitable equipment without implied obligation on your part. Send today for our new bulletins showing the application of electric power to mine problems. State whether interested in hoisting, pumping or locomotives.

EDITORIAL

T. A. RICKARD - - - - Editor THOMAS T. READ - Associate Editor

"AND where do I come in?" says the silver miner. "Why don't they use silver bullets or silver-plate their shrapnel?" We sympathize. Silver is almost the only metal that has not risen, for gold in matters of this sort is *hors concours*.

OVERTURES looking to a settlement of an apex conflict over new discoveries of ore having failed between the Empire and North Star mining companies at Grass Valley, we regret to announce the probability of immediate litigation.

AUSTRALIA has placed an embargo on the export of zinc-dust. This went into effect on June 15. Some of it was coming here and some of it was going to South Africa. The embargo will affect the price here by decreasing competition for domestic product.

QUICKSILVER likewise has taken another jump, to over $90 per flask of 75 pounds. The Japanese are drawing on California, so also South Africa. Mining for quicksilver in California, Nevada, and Texas should profit thereby.

INDUSTRIAL corporations manufacturing munitions are making enormous profits and consuming great quantities of the base metals. It is estimated that these "converted arsenals" have obtained contracts already to supply $500,000,000 worth of material, of which as yet only $30,000,000 worth has been shipped.

IMMIGRATION to the United States during the first eight months of the present fiscal year made a net addition to the population of only 14,269, as against 601,000 in the corresponding period of the previous year. That is one of the important consequences of the War. Unemployment is diminishing; a scarcity of skilled labor is anticipated.

ALREADY the rise in metals has had a favorable effect on the shares of the big metal-producing enterprises such as the American Smelting & Refining, the Guggenheim Exploration, Federal Lead & Mining, United States Smelting, Refining & Mining, United States Reduction, New Jersey Zinc, and kindred companies. As yet it has not caused the starting of new undertakings in proportion to the improved outlook, but many of them are being incubated and will be in evidence shortly.

FLOTATION processes are gradually finding a place in treatment plants throughout the world. The annual report of the Seoul Mining Company, Korea, states that during 1914 a flotation plant was started in the Suan mill. Gold extraction was increased from 82 to 88%, and copper from 20 to 75%. The ore contains these metals and bismuth. There are many other mines in the world that have gold ore containing minerals interfering with cyanidation but removable by flotation.

LEAD was dull for three or four months previous to the last week in May. Thereupon the price increased by $50 per ton within three weeks. This was due to the disposal of an accumulation of the metal and the sudden demand in the manufacture of terne-plates or roofing-tin. The American Smelting & Refining Company has the whip-hand, for the independent smelters appear to have no lead to sell for delivery in the next two or three months. The St. Louis price has exceeded that quoted at New York, while under normal conditions the reverse obtains. This market, like that for the other base metals, is in an excited state and surprises may be expected.

GOVERNOR Hiram W. Johnson has signed the Maddux bill, intended to provide measures for protecting the oilfields against underground water. The new law places the matter under the jurisdiction of the State Mining Bureau, and compels the oil-operators to file all necessary data with the Bureau. Engineers are to be stationed in various localities, in order that proper facility be given for the operation of the law. Legislation upon the matter of water infiltration in the oil-sands of California has been agitated for a number of years, for the untold damage arising from this cause has long been recognized; but until this recent session of the legislature it seemed impossible to get the various op-

erators to agree upon the best means of regulation. The State Mining Bureau was requested to assist the oil industry, and its efforts have finally met with the hearty co-operation of all oil-operators, resulting in a means of regulation to which there has been no opposition, and through which great benefits to the industry should ensue.

GOLD production generally has not suffered from the War because so little of it is derived from Europe. Even the big mines of the Transvaal, owned by English, German, and French shareholders continue to produce their quota of the most necessary metal, despite the national conflict that compels the dividends of some of the shareholders to be set aside until peace is restored. In Rhodesia, West Africa, India, and Australia the output of gold is well maintained, thanks in part to the arrangements made by the British government for advancing 97% of the value of the gold upon its delivery at the local banks, and also the facilitating of cyanide shipments to the mines. On this continent gold production proceeds as usual and in Asiatic Russia the operations in the Lena and other gold-producing districts have been hindered only by an occasional shortage of labor due to mobilization. On the whole, the main sources of supply are not affected by the War, but new ventures are without the capital to make them active, and will continue to feel the lack of it, as regards London, for the British Treasury has placed an embargo on new issues. Therefore the total output of gold in the world will suffer decrease now and a more marked diminution later, for the reason stated and also because fresh enterprise will be diverted to the exploitation of the base metals, the price of which, relatively has been rapidly enhanced.

The Base Metals

The sensational rise of copper, antimony, and zinc has been followed by a vigorous spurt in the quotation for lead. These changes, all favorable to the miner, are largely the result of the War, in the waging of which enormous quantities of munitions are required. The demand for copper and zinc indicates the increased use of brass; the consumption of lead seems to need no explanation, for it is the metal generally associated with war; but in this case the obvious is not the fact. The consumption of lead in modern warfare is small, as compared with steel and brass. Lead has risen because it is being employed as a substitute for zinc, in the making of terne-plates or roofing-tin, instead of galvanized iron. Antimony is added to the lead in bullets to harden them. Subjoined are the prices of the principal base metals at three successive periods, namely, just before the War, during the collapse following the naval blockade, and on the day of this writing. The figures are eloquent. For further information we give the ratio of production and consumption of the principal base metals in the United States as compared with the grand totals of production and consumption in the whole world.

PRICE IN CENTS PER POUND

Metal.	July 3, 1914.	October 14, 1914.	June 14, 1915.
Copper	13.35	11.40	20.50
Lead	3.90	3.60	7.25
Zinc	4.75	4.55	26
Antimony	6.90	11.00	36
Tin	30.75	30.00	42.50

	Copper	Lead	Zinc	Antimony	Tin
Percentage of world's supply produced in U. S.	55	34	32	..	..
Percentage of world's production consumed in U. S.	37	33	26	40	43

It will be seen how enormous is both the absolute and the relative consumption of the three chief metals in this continental country, in which material civilization has been so highly developed. Two of the base metals are not produced in the United States in notable amount. Of antimony there is only about 2500 tons, obtained from the smelting of antimonial lead, mostly of foreign origin. The antimony of the world, amounting to about 20,000 tons per annum, comes chiefly from China and France. The supplies of the latter come from its south-eastern territory, outside the war area, while delivery of Chinese antimony has been hindered by the disorganization of transport. Mexico has recently become of importance in antimony production, and Canada has resources capable of making a considerable contribution of this metal. Of tin also it cannot be said that any noteworthy amount is produced in this country: only about 50 tons per annum, chiefly from Alaska, as against a world's production of 120,000 tons.

In normal times Germany consumes about one quarter, say, 250,000 tons, of the world's production of copper. As imports have stopped, it is presumed that Germany is employing a substitute and also using the manufactured copper in the country. England and France are buying copper freely. As for zinc, apart from the increased demand for making the brass used in munitions, the diminution in the supply of that metal from Australia has proved an important factor. The Broken Hill mines, which produce normally about 200,000 tons of zinc, or one-fifth of the world's output, are unable to market their produce because they are under contract to the Belgian and German smelters. Some of the Australian zinc concentrate has been shipped to this country, but the freight and duty are unfavorable, as well as the fact that a better grade of domestic material is available here for smelting. Meanwhile we note that the British government is to commandeer all the zinc produced in Great Britain—normally 60,000 tons per annum—and stop the use of it for galvanizing. On this side the United States Steel Corporation is starting to replace lead by zinc in galvanizing, making the terne-plates to which reference has already been made. Undoubtedly one of the effects of the War will be to stimulate the inventive faculty in substituting one metal for another in accordance with the exigencies of supply; some of these substitutions will be temporary, others may persist after peace has been restored. Extraordinary variations in price may favor the temporary use of one metal in the

place of another, but it is quite clear that the general demand for all of them is being enormously intensified by the War.

The question arises, will this demand stop on the termination of hostilities? As we see it, the demand will persist while hostilities continue and also during the interval that must elapse between the cessation of actual fighting and the final consummation of peace. During that interval each belligerent country will begin the work of re-organization, and as soon as peace is assured the great work of rehabilitation and restoration will be taken in hand. That will involve an enormous consumption of metals. Modern man needs food and clothing first, then the metals. The destruction of metallic products of all kinds, from domestic utensils to intricate machinery, has been intense in Belgium, Northern France, East Prussia, Poland, Galicia, Serbia, and other regions traversed by devastating armies. All of this will have to be replaced, besides which there is the probability that a good deal of old non-metallic material, now destroyed or yet to be destroyed, will be replaced by metallic products. As we see it, the next decade will be marked by an intensified demand for the base metals, causing a world-wide expansion in the mining of these metals. This country, as the great maker of munitions now and the great manufacturer of machinery during the first years after the War, will be called upon both to produce and to smelt the base metals on an enormous scale.

The Mine Safety Conference

An extremely interesting meeting was held in San Francisco last week. As most of our readers know, a workmen's compensation law has been enacted in California and an Industrial Accident Commission, consisting of Messrs. A. J. Pillsbury, Will J. French, and Harris Weinstock, has been organized to have jurisdiction over all industrial accidents in the state. The law creating this Commission is broad in its scope, so that it has power not only to compensate injured workmen, but also to take suitable steps to lessen the occurrence of accidents. In the performance of this duty it has caused to be devised the set of tentative mine-safety rules that we discussed editorially week before last. On Friday and Saturday, June 11 and 12, public hearings were held to discuss these rules, in order that they may be as satisfactory as possible before being put in force. The hearings were attended by 30 or 40 men, among them the managers of nearly all the most important mines in the state. The rules, which make a printed book of some 66 pages, were discussed seriatim, the conference extending over two days. Much valuable information was elicited and various different points of opinion were developed. We hope at a later date to be able to give details of the discussion, but there are several features of the meeting as a whole that deserve immediate comment. The most important is the spirit that animated the conference. It does credit to the mining profession that two or three dozen busy men should leave their mines and spend a couple of days in San Francisco for the purpose of devising the most satisfactory and efficient set of safety-rules, and not for the purpose of evading or defeating them. It was only in rare instances that any of the engineers present expressed the belief that the precautions proposed could not be enforced without serious financial damage to mining interests, and it was interesting to note that such objections were almost invariably made by the older men in attendance.

Another point of interest is that no representatives of the workmen were present at the conference. It might be supposed that the men who directly benefit by safety precautions would be the most interested in these rules, but the reverse is the case. The tentative set of regulations was drawn up by a committee of seven, three of whom were representative of miners' unions, but we understand that none of these three attended any of the meetings of the committee, their part in the work having been confined to correspondence. The altruistic character of the meeting also impressed the listener. None of the men present were advancing their own interests; they were considering the rights and needs of others. Frequently an operator would remark of some proposal that it was perfectly feasible at his own property, but it could not be done by some small operator who only employed a few men. Not a little discussion centred around the duties and rights of 'leasers.' Mr. C. M. Bradley, the legal advisor to the Commission, made it quite clear that they are not 'lessees' in the ordinary sense of the term and that their exact status will probably have to be determined by the courts. Much of importance hinges upon the question whether they are employees of the mine-owner or not, and this, as well as other points, will have to be elucidated. The California Metal Producers Association has taken a useful part in co-operating with the Commission with a view to establishing suitable regulations. It is certainly worthy of note that the mining industry in California is regulated by a Commission anxious to meet the needs and wishes of the operators, who in their turn are lending every effort to facilitate and perfect its work.

Learn Spanish, Also Russian

In a recent interview with an American journalist, the President of Peru, General Oscar R. Benavides, is reported to have said: "Urge the American people to insist that Spanish be taught in every high school in your land." That advice General Benavides, himself graduated from a well-known mining school, might give with particular emphasis to those about to begin the career of a mining engineer. In other departments of human activity, other languages may be dominant: in diplomacy, French; in many branches of trade, German; in the mercantile marine, English; but in the mining of the metals, omitting iron, the three languages necessary to the resourceful mining engineer are English, Spanish, and Russian. English, fortunately for those who speak it, is the official language of many of the principal min-

ing regions of the world, and more particularly of those countries from which comes three-quarters of the world's output of gold. Next in importance is Spanish, and the greater importance of it is inevitable as the vast mineral regions between the Rio Grande and Tierra del Fuego are given political stability and orderly government. In Brazil, of course, Portuguese is necessary; and Portuguese is not bad Spanish, as some people think. Undoubtedly the range of territory over which Spanish is the official language includes an enormous extent of country interesting to the miner. The graduates of our American mining schools should be impressed with the idea that a knowledge of that beautiful language is an accomplishment of the greatest practical value at the beginning of an era that promises to be marked by an industrial *rapprochement* between the Americas. Next, Russian. Unlike our own or the Spanish language, difficult to learn, Russian also is destined to be necessary to the accomplished engineer ready to be at the front of mining enterprise. Already several engineers, notably half a dozen Californians, have made their mark in the Anglo-American efforts to develop the mineral resources of Siberia. If they have succeeded, it is due largely to co-operation with the Russians themselves. Co-operation is impossible without the mutual understanding that is based on a linguistic medium of ideas. In order that the friendly co-operative development of the gold and the copper, the silver and the lead, deposits of Siberia may be accelerated after the War has ended it is necessary that American mining engineers, and English too, should learn Russian, to the extent, at least, of being able to dispense with an interpreter. No man can learn to understand the people of a country through the refractive medium of an official interpreter. We give this advice to the younger men; we give it also to some of the older, now left with spare time on their hands. Use any interval of comparative inaction to learn one of these two languages, if neither has been acquired; if one is already conquered, attack the other. When opportunity knocks at the door, she does not wait for an interpreter.

Mining Law in Alaska

On April 20, 1915, the legislature of Alaska revised its territorial mining code as adopted in 1913 at its first session. The revised code is more logically arranged. The 1913 law gave evidence of having been hastily prepared, while the 1915 enactment shows the result of deliberation. In the main, this law is patterned after the usual form of supplemental mining legislation adopted by most of the States and Territories of the West. The steps necessary to make valid lode and placer locations are fully outlined, and the new Act adds provisions for locating tunnel-rights and mill-site claims. The provisions of the 1913 Act requiring certain preliminary or discovery work have been eliminated. The drastic requirements for annual labor or assessment work are retained. These make it obligatory to file proof of labor if the validity of the location is to be preserved, and any false statement contained in these affidavits renders the party making them, or the party procuring them to be made, guilty of perjury or subornation of perjury and punishable by severe imprisonment. This feature is an attempt to enforce the salutary annual labor requirements of the general mining law, which in Alaska especially had become subject to gross evasion and laxity. Another abuse is corrected by a more elaborate section governing and limiting the location of claims under powers of attorney. This part of the new code is largely a re-incorporation of the Act of Congress covering the same subject, passed in 1912.

Some interesting provisions concerning annual labor merit attention. It is provided that the cost of the survey of mining claims by a United States Mineral Surveyor may be credited as annual assessment work. It will be interesting to see what view the Courts will take of this new provision, since it does not meet the test usually applied, namely, that the annual work or labor performed shall directly facilitate the extraction of mineral from the ground. Of course, it can be argued that this character of work is not more foreign to the case than the services of a watchman, which have been held by some Courts to be properly credited as annual labor. It is extremely doubtful, however, whether the Land Department will allow the costs of such survey-work to apply as patent improvements, even if the Courts should hold it satisfactory for the purpose of keeping the claim alive.

Another interesting provision is the requirement of the performance of $25 worth of annual labor on a mill-site claim, or in lieu thereof the payment of $25 annually to the Territorial Treasurer of Alaska, for the enactment of a similar provision has been suggested as applicable to mining claims, namely, the payment of $100 annually to some Government official in lieu of assessment work. The latter could only be accomplished by an act of Congress, but the mill-site provision in Alaska is not open to the same doubt, since the Federal mining law does not require annual labor to be performed on mill-sites.

Other changes in the new law are of minor importance. Taken as a whole, this new enactment is a step in the right direction, and is a material improvement over the Territorial Act of 1913. Such improvement is traceable to the fact that the terms of it, and its passage through the legislature, are due largely to the efforts of the Alaska Mining and Engineering Society, which debated the defects in the old regulations and suggested the changes necessary at two meetings to which the Joint Committee of the Senate and House on Mines and Mining was present by invitation. This is an example that other legislative committees might copy with advantage. The Engineering Society includes the mining engineers connected, as consultants or managers, with the more important mining operations in Alaska. Hence the discussion of the changes required in the existing law was of a most practical character. The result, as seen in the terms of the amended law, will commend themselves to experienced men.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment

Assay of Ore Containing Metallics

The Editor:

Sir—I have read with interest the article in your issue of April 24 on the assay of ore containing metallics, in which is given the method used at the Omaha plant of the American Smelting & Refining Company. As printed it reads as follows:

"The main point of the method lies in the fact that 10 assay-tons of the sample must be taken, bucked-down, and all its metallics must be reduced to find the total amount of gold and silver contained therein."

From the second example in the article I take the following:

"From 10 assay-tons there was secured 0.012 assay-ton of metallics which contained 97.83 mg. Au. The pulp assays 96.8 oz. Au per ton."

The calculation is as follows:

```
  10.000
   0.012
  -------
   9.988
  96.8
  -------
  79904
 59928
 89892
 -------
 966.8384
  97.83
 -------
 106.466
```

I wish to call attention to the fact that in this computation no allowance is made for loss of weight in bucking-down, which would range from 3 to 6% or even greater when the ore contained combined moisture. It would average at least 4%. In the case of 4% loss in the computation, presuming that the loss on the bucking-board was proportionally divided between pulp and metallics, the computation should be as follows:

```
Taken  10.000  A.T.
Loss    0.400  "
       -------
         9.600  "  on which to compute value
         0.012  "  metallics
       -------
         9.588  "  pulp
At       96.8
       -------
        76704
       57528
      86292
      -------
Contains 928.1184 mg. Au
Metallics 97.83
```

Contain 1025.948 mg. Au in 9.6 A.T. ore.

1025.948 divided by 9.6 equals 106.87 oz. gold per ton of ore.

In other words, the smelter in such cases would pay 0.404 oz. less gold per ton than was contained in the ore. By the method quoted in every case where the metallics enriched the assay the ore-buyer is benefited by the error of not computing loss of weight in bucking-down.

RICHARD MARSH.

Spokane, May 8.

[Our correspondent is apparently overlooking the fact that in smelter practice all samples are dried to constant weight before assaying. Loss by dusting would affect the gold content of the metallics, but would have no effect upon the results on the pulp. The error from dusting is probably of a less order of magnitude than the sampling errors.—EDITOR.]

Melones Mining Company

The Editor:

Sir—My attention has been called to a report on the Finnegan & Finnegan Extension mines, situated at Carson hill, Calaveras county, California, signed Edwin N. Hawkins, E.M., and dated Denver, Colorado, October 1, 1914.

This report contains several unfounded and erroneous statements regarding the Melones Mining Company, which operates the adjoining property, and as the management is quoted as authority for these statements, I wish to correct the false impression which they might cause.

The report states "It is estimated by the Melones company that they have ore reserves good for 75 years." The Melones company has never had ore reserves of this size at any time in its history and it would be absolutely impossible to ever have them. The company has had ore reserves in sight for as much as three years, but usually has only two years' supply blocked out.

It is further stated that "Pocket or nugget value of ore (not included in above or run-of-mine ore) is $150,000 or $200,000 annually." As a matter of fact the average annual returns from this source are about $1500, notwithstanding the fact that in 1911 one pocket was discovered which contained about $5000 in coarse gold. This is the only occurrence of the kind of importance which has been found since operations were started in 1903.

It is also said that "Present annual net profits of Melones company as stated by those in authority at mine and mill are $400,000." This is untrue; no one in authority ever made such a statement. The Melones Mining Company has never paid a dividend and has paid no

interest on its bonds since 1906; consequently its operations have been unprofitable.

The management of the Melones Mining Company cannot in fairness to itself or the public let statements of this character pass without correcting them.

WILLIAM G. DEVEREUX,
Manager Melones Mining Company.

San Francisco, June 3.

Speculation in Mines

The Editor:

Sir—I have read with interest the many articles published in the PRESS under the head of mining investment and prospecting. There are two things that affect the mining industry more vitally than all others:

(1) The eliminating of the grafter from mining and the enacting of adequate laws in mining states to protect the investor.

(2) The placing of mining operations into the hands of experienced and technical men where it properly belongs.

In regard to the first phase: There have been hundreds of thousands of dollars invested by people, the world over, who never knew what they were buying or what use was made of their money. To illustrate: In the camp of C— a promoter incorporated a company and sent glowing descriptions of property to Eastern stockholders. He had no mining property or assets of any kind. Upon receiving word of a visit from a client he promptly located some wild-cat claims and saved himself from imprisonment. In the same camp an engineer told me he was engaged to examine the Minnie mine by a wealthy manufacturer who had invested $30,000 in the property. It was supposed to have a working-shaft and be equipped with a hoisting-plant. From inquiries, no one in the district knew or even heard of the Minnie mine, but on looking up the county-records the engineer found it consisted of 10-ft. holes in a sagebrush flat, utterly worthless for mining or even grazing land.

The above investors thought they were buying mining stock and roundly condemned mining, while as a matter of fact, they bought individual stock incorporated for the purpose of paying the personal expenses of Joe Busch and Sam Jones.

Another form of operation is the incorporation of companies for the purpose of providing positions for managers and an office-staff. Very little goes into development; they are seldom mining men and sometimes go so far as to erect mills to extract metals from granite and other rocks. The only way it could possibly be made to pay would be to devise a method of putting gold into the rock to be treated. A stockholder in a company of this sort in Arizona asked a miner where the pay-streak was. The miner, laughing, replied it was back in Philadelphia; on returning the stockholder promptly shut the mine down.

In a Nevada camp Mr. ———, a promoter, had an excellent showing in a porphyry dike on the east side of a granite mountain easily and cheaply developed by shaft. He drove a long adit in barren granite on the west side of the mountain, drew a salary as manager, and let private contracts for work to the superintendent. He said that an adit is a satisfactory way of raising money from stockholders; you always had a mine ahead so long as you didn't hole through the other side of the mountain. Assessable stock is desirable, as salary is always forthcoming and no thought is ever given to opening a mine or making good the stockholder's investment.

Another form is the organization of companies for the purpose of gambling in shares on stock exchanges. This is less pernicious than the other two, as capable men are sometimes employed and good mines developed. All of these are outside the province of real mining, which has for its object the profitable development and extraction of ores and minerals.

Mining is an industry as honest as tilling the soil, when properly conducted. Frauds designed to extract money from the public under the name of mining should have been stopped years ago. It has retarded the development of mineral resources and absorbed capital that could be profitably used in legitimate mining and creating new wealth. A mining investment in the hands of capable and honest men is as safe and often more profitable than any other form of investment.

The second method of placing funds into the hands of inexperienced men is almost as great an economic waste as the first. Every district has monuments of ignorance in the shape of old mills, adits, and shafts. You are simply paying for some one's education, which is likely to be rather expensive and highly unprofitable.

It is a curious fact that if employment is sought as manager in any manufacturing or industrial branch outside mining, you are required to furnish evidence of qualification. For instance, a farm-hand with no experience applying for the job of captain of an ocean liner might be seriously questioned as to his sanity, but a drug-clerk or anyone that couldn't tell the difference between a chunk of ore and a cream-puff is supposed to be capable of opening and developing a mine where intricate questions of geology and metallurgical treatment of ore are involved.

I do not agree with the views of a brother prospector published in a recent article. Something that would help the mining industry is a change of attitude by the operator toward the engineer and a change of attitude by the engineer toward the prospect. The question put to the engineer should be: "Will the property warrant the expenditure of a given sum in development?" Not: "What will the property be worth when developed?" It is a physical impossibility for an engineer or anyone else to stand on the surface and tell what rock will assay one hundred or a thousand feet underground.

The experienced engineer and the trained geologist are better qualified than anyone to map out a plan of development and if the handicap of prospect valuation were removed many promising prospects now turned-down would be developed into dividend-paying mines. The practical mining man, miner, and prospector who understands the character of ore deposits on a property

often makes an efficient and successful manager, because he has local knowledge.

The prospector and engineer should work together in bringing out new properties. The engineer should take the place of the promoter, and investment be made direct through him. This would cut out fraudulent promotion, give efficient management, and accomplish the purpose of putting money directly into mining.

The majority of failures in mining and the commercial world are made by people who knew nothing about the business they entered. Bonanza orebodies will manage themselves, but the greatest quantity of the precious metals is now mined from low-grade ore that requires the services of experienced and technical men to make a profit. New discoveries and orebodies will be forthcoming as long as man digs and there are as great opportunities as ever for profit if mining is handled in a business-like way. In searching for new mines a distribution of risks over several properties is better than putting all the capital into one.

Caps and Fuse

The Editor:

Sir—I wish to give a word of advice to those who are using caps and fuse. If they will use a little black gunpowder in the cap before putting in the fuse, they will have no miss-fires. I have used it many years and find it excellent. I have used caps, of which not more than three out of five would explode, but after using gunpowder there was no miss. I just have a little black powder in a cap-box and dip the cap in the powder, just enough to cover the fulminate, then insert the fuse and crimp the cap. I have even tried this after dipping the cap in water, and find it will explode. Please publish a piece in your paper, so others can see it. I am quite sure anyone that will try it will never do without it, and if they should have a miss, they can be sure that it is the fault of the fuse and they should give it plenty of time before going in, as it has been known that fuse will hold fire for 15 to 30 minutes.

Automatic Dressing of Amalgamated Plates

The Editor:

Sir—In your issue of May 15, E. S. Boalich describes the method devised at the Duplex mill, at Searchlight, for automatically dressing plates by means of a traveling brush to rid the plates of the objectionable galena that settled thereon. The Editor suggests that more water should have been used to give a higher velocity to the pulp over the plates. Unfortunately, Mr. Boalich did not mention the grade of the plates, but he did mention that the gold was surprisingly free.

Recently I visited the Duplex mill, which is in ruins, and out of curiosity I measured the inclination of the tables and found them to have a grade of 1¾ in. per foot. The 10 stamps are light in weight, which accounts for their low capacity, even with plenty of water.

Searchlight is in a desert country where water is scarce and distillate is expensive, so that economy of water is of prime importance; all that used in the mills coming from the mines at a depth of 200 ft. or more, so that the suggestion of more water would hardly be justified. The conditions, in my opinion, required the plates to be of greater inclination, 2½ in. per foot being none too great. This would have given a greater velocity of pulp over the plates with less water and would no doubt have kept the galena in motion so that the automatic feature could have been dispensed with. The inventor's ingenuity was misdirected in complicating an otherwise simple operation. I have had considerable experience with gold-galena ores and have had no difficulty in keeping the galena in motion and the surface of the plates free to amalgamate. The objection to the automatic brushing of plates under a stream of pulp is that amalgam is liable to be dislodged and carried away with the current; if this were not so it would not be necessary to hang up the stamps while dressing plates.

Possibilities of the Mother Lode in Depth

The Editor:

Sir—I have read with pleasure the several articles in the Press written by W. H. Storms, descriptive of the Keystone mine in Amador county. They have added very much to the interest I have always felt regarding that great representative of the Mother Lode formation in California, as I first visited it in 1872 with John W. Gashwiler, and in 1893, when I was superintendent of the San Francisco Mint, I gave O. C. Hewitt a position there. His service as superintendent of the old mine ended by its closing operations, and he passed the remaining days of his life in Government employ with satisfaction.

At my suggestion Mr. Hewitt obtained from the original locator of the Keystone mine, J. T. Wheeler, the following letter, which, as it adds some detail to Mr. Storms' account, may possess sufficient historical interest to justify its publication.

John Daggett.

Black Bear, May 28.

Pine Grove, August 19, 1896.

O. C. Hewitt, Esq.,
San Francisco.

Dear Sir:

In regard to quartz mining at Amador in the early days, I will do the best I can for you. The first location made was by Thomas Rickey on the north side of Amador creek and called the Original Amador Company. The next was on the south side of the creek by Herbert and Davidson, two preachers, and called the Spring Hill. The next location was the Granite State Co., and then the Pleasant Ridge Co., on what was then supposed

to be a parallel vein to the Spring Hill. These two claims in after times became the famous Keystone, from which so much gold has been taken. The Granite State Co. commenced near what is now known as the Eclipse shaft, and ran south 720 ft. Then came the Pleasant Ridge Co., but I do not know how much they claimed. The Granite State claims were located by myself; J. T. Wheeler, my brother Charles C. Wheeler, Jos. E. Leighton, John Grant, J. D. Goodrich, and T. S. Hoyt made up the company. One hundred and twenty feet in length by sixty feet in width was a claim. On one claim the croppings were heavy and rich. We hired Mexicans to build four arrastras for us, and by selecting the ore made it pay $100 per ton. We worked in this way a few months, when a party came over from Georgetown and after an examination made us a proposition to build us a 12-stamp mill for one-half of the property, which we accepted. This party included John Conness, Selucius Garfield, Mr. Robinson, and a Mr. Williams, all of Georgetown, California.

The mill was built and accepted. We crushed a good deal of ore, but we knew nothing of amalgamation, and no doubt lost more gold than we saved. Things went on in this way until the following summer, when my brother died of typhoid fever, and I got caught in a cave in the mine, had my leg broken and my foot badly crushed, which laid me up for 13 months. In the meantime the company got a few thousand dollars in debt, was attached, and sold out by the sheriff. A. H. Rose purchased the whole outfit. He was a member of the Pleasant Ridge Co. and in time became general manager of the Keystone.

For more than ten years, however, the Granite State Co. claims remained idle, until an old countryman named Domanick Burke made an arrangement with Rose for the sinking of a shaft and other work, which led to the opening up of a big body of rich ore between the old workings and the creek. From this orebody millions of dollars worth of gold have been taken, of which you know more than I do. A. H. Rose soon sold out to Gashwiler and McDonald for $102,000. Since then the Keystone company has obtained more ground, bought the Spring Hill and, I think, other claims, but with these matters I am not familiar.

Yours very truly,

J. T. WHEELER.

Efficiency of Tamping

The Editor:

Sir—The article on this subject by Edgar A. Collins in a recent issue of the PRESS, purporting to give results as obtained by him at the Commonwealth mine, is a good example of incomplete data concerning operation, that proves nothing. While not doubting for a minute that the stemming or tamping of holes increases the efficiency of the powder, I am unable to see, from the data given, where Mr. Collins has demonstrated this theory. The point of the whole matter is this: has he succeeded in breaking a greater amount of material with the same or a smaller amount of powder per ton? His experiments show a smaller amount of powder per hole, a greater number of holes, and no estimate of the amount of material broken. He does not state whether or not the holes were shallower in January, February, and March than those of the previous three months, and it is absolutely impossible to draw any conclusion from the data given. He also states that the holes may have been closer together, and if such was the fact, it would take, quite naturally, a smaller amount of powder per hole to break the ground. According to the figures given, if the same amount of ore was broken in January, February, and March as in the previous three months, he not only used 1418 pounds more of powder, but also expended 45 shifts of labor in gathering clay for tamping. Of course it may be possible that this is only a preliminary article by Mr. Collins and the full data will be given later.

H. C. CUTLER.

Reno, June 1.

[In consequence of Mr. Collins's article, the matter is now being tested on a systematic scale in one of the leading gold mines of California. We expect to publish the results in good time.—EDITOR.]

The Search for Platinum

The Editor:

Sir—I read with much interest your editorial on the search for platinum, in the issue of May 15, and particularly the reference to the Rambler mine. The Platinum Mining & Milling Co., incorporated lessees of the Rambler mine, has been working it for some time. The mill has been re-modeled and is working satisfactorily. During the first six months the dump alone was worked, there being a large quantity of platinum ore available from this source—sufficient for many months.

Within the last two months the mine has been unwatered. The limited development work done during that time has disclosed a large body of milling ore, apparently lying on the foot-wall, carrying considerable amounts of platinum and the platinum metals. The extent of this orebody is unknown as yet; at the present time it is exposed on three levels. The width varies considerably, but so far has, wherever cross-cut, exceeded eight feet. There is sufficient ore already developed to run the mill, which has a capacity of 50 tons per day, for a year. This is all platinum ore, although it carries considerable copper and some gold and silver. Until negotiations, now under way, for the marketing of the product are completed, I shall be unable to make public the assay-value of the ore and concentrate. However, instead of being exhausted, I believe I can safely say that the platinum deposit of the Rambler mine has scarcely been touched. The high-grade ore, found near the surface, was, as stated, quickly exhausted, but the main vein from which the ore will come has until recently been ignored by everyone that has ever worked the mine.

HOWARD D. GRAY.

Holmes, Wyoming, June 2.

Grass Valley Re-Visited—I

By T. A. RICKARD

When I went to Grass Valley the other day, I recalled the fact that it was 29 years since my first visit. At that time Emile R. Abadie was in charge of the North Star mill, and I remember being impressed by the contrast between the short quick drop and shallow mortars as compared with long slow drop and deep mortars of Gilpin county, Colorado, where I had been obtaining my first acquaintance with stamp-milling. That contrast provoked me to study the subject and to write a book* upon it, the first copy of which I saw at the Londonderry mine near Coolgardie, in Western Australia, in 1897. Inexperienced as I was in 1886, I noted a childish defect in sluice-plate in the Californian mills of that day was a legacy from the placer mine, as its name indicates. It is a 'sluice,' suited to the rapid passage of pulp, and of its precious contents, to the dump. The alluvial digger left his impress in the stamp-mill much too long. Now the millman turns to his old-time partner and tells him that his efforts to concentrate gold from amid a big volume of unsorted material is futile. He invites him to take a lesson from the experience of stamp-milling and concentration.†

Mines are wasting assets and mining communities are of uncertain vitality, normally. It is a delight therefore

GENERAL VIEW OF THE NORTH STAR MILL AND SHAFT.

the design of the amalgamating tables in the North Star mill. In front of the latter came an apron-plate 4 ft. 5 in. wide, equal to the full width of the mortar, but only 2½ ft. long; this narrowed so as to discharge onto a sluice-plate 12 ft. long, but only 22 in. wide, that is, one-half the width of the apron. The scouring action of the pulp had rubbed the sides of the amalgamated surface of the plate so as to lay bare the copper. Naturally the question was asked how the millman expected to catch fine gold under such conditions? When I revisited the mill in 1893 these foolish sluice-plates had been replaced by an apron 16 ft. long. In the interval the Rittinger shaking tables, made of copper and intended to catch escaping amalgam, had also been discarded; the same purpose being effected by the ampler lower surface of the apron-plate. Indeed, the narrow to find oneself among mines that seem to have the enduring quality of the widow's cruse of oil, and to revisit a settlement that appears permanently prosperous. The pretty town of Grass Valley was founded in the Golden Age; the first mining in 1849 was alluvial, but in June of the following year the first vein was discovered, and in October of the same year an outcrop of rich gold-bearing quartz on Gold Hill started vigorous prospecting. The first mill in the district was erected in January 1851, on the west bank of Wolf creek. The stamps consisted of tree-trunks shod with iron‡. From 1851 to 1866 the Grass Valley district yielded gold to the value of $23,000,000. From 1866 to 1915 the output

*'The Stamp-Milling of Gold Ores,' 1896.

†'The Metallurgy of Alluvial Mining,' by John M. Nicol, Mining and Scientific Press, May 29 and June 5, 1915.

‡'The Empire Mines, Past and Present,' by George W. Starr, Mining and Scientific Press, August 4, 1900.

has been fully $100,000,000 more. At the present time the mining activities of the district are largely identified with the operations of two big enterprises, the North Star and the Empire. Both represent consolidations and absorptions of smaller properties formerly well known. The Empire includes the Pennsylvania, which had previously swallowed the W. Y. O. D. and a number of claims adjacent to the Empire, also most of the mineral rights under the town. The North Star includes the New York Hill, the Gold Hill, the Massachusetts Hill, the Irish American, and many individual claims.

The two principal mines are examples of persistent enterprise. This is matched by continuity of ownership. The Empire has been owned by W. B. Bourn since 1874, when he inherited the property from his father, who bought it in 1869. George W. Starr became superintendent in June 1887; he left for South Africa in August 1893, returning to Grass Valley in April 1898, since when he has been in charge of the Empire mine uninterruptedly. That is one reason for its prosperity. Incidentally, I may remark that not often an engineer leaves a mine to return to the management of it five years later. Moreover, great as has been the development of the Rand, it is doubtful if the mines (controlled by Barnato Bros.) to which Mr. Starr was attached during his stay at Johannesburg bear stronger marks of vitality than the old mine at Grass Valley. The North Star furnishes a similar story. Mr. Bourn re-opened this mine in 1885 and sold the control to James D. Hague in 1886. Arthur De W. Foote became superintendent in January 1895 and resigned in favor of his son, Arthur B. Foote in 1913. While James D. Hague has gone, alas! his son William is now the managing director, resident at the mine, so that each of these families has given two generations to its service. Moreover, James D. Hague was interested in both the Empire and the North Star properties, being president of both companies until 1896, when the two enterprises became separate. The names of James Douglas and George B. Agnew on the directorate suggest the fact that members of the firm of Phelps, Dodge & Co. have held an interest in the mine for many years, together with other men of prominence in New York. Mr. Bourn also has achieved distinction in other directions, for he is president of the Spring Valley Water Company, an enterprise of large importance to the people of San Francisco and one over which much controversy has raged in consequence of the effort made to acquire it for the municipality.

In the midst of the town a little mine called the Golden Center is doing well, supplying a 10-stamp mill on Wolf creek. It is controlled by Sacramento people and managed by Charles Brockington as superintendent. While as yet only 700 ft. deep, it is said to be opening up well. This is also an old mine rejuvenated, for it was originally known as the Dromedary. About 1½ miles east of the town is the Union Hill mine, with a 20-stamp mill. It is owned by San Francisco and Pasadena men who assumed control in September last. Since then the shaft has been sunk from 600 to 800 ft. Another notable old mine is the Brunswick Consolidated, which is on a vein parallel with the old Idaho-Maryland. A 20-stamp mill is supplied with ore of good grade, a new vertical shaft with a steel head-frame has been started, as well as grading for 20 more stamps, and a cyanide annex. Chris Mallon is the superintendent. The mention of the Idaho-Maryland recalls two famous mines, for both the Idaho and its extension on the ore-shoot, the Maryland, were great producers in their day. When reasonable terms are acceptable, it is likely that deeper exploratory work will be undertaken on this property.

The North Star Mines Company operates two mills: the North Star, built in 1886, and the Central, built in 1904. Both contain 40 stamps, of the same weight (1050 lb.), falling the same height (6½ to 7 inches) at the same rate (106 drops per minute). The crushing capacity is the same: 4500 tons per month, the duty being 3.8 tons per stamp. The wooden battery-frames in the older mill were replaced last June by cast-iron posts, on concrete foundations, while the younger mill was built with steel battery-frames on concrete foundations. As far as I could learn, these departures from conventional practice have proved neither a success nor a failure. In the Central mill the vibration seems excessive, for the noise is higher pitched. It sounds sizzling. This new mill has masonry bins with steel-plate fronts.

In the old mill, a good measure of the durability of seasoned wood is given. The battery-posts of sugar pine have been replaced from time to time. In 1906 seven old posts were replaced by new ones made of spruce. In 1911 another was replaced similarly. Two of the original posts were taken out in June 1914; at the same time the spruce posts were removed; they were rotten already.

In substituting cast-iron for the wooden battery-frames in this 40-stamp mill it was necessary to use 12 posts, each weighing 4000 lb., the cost at the Taylor foundry in Grass Valley being $250 apiece; also 16 H-beams weighing in all 5568 lb., the cost being $227.50. The total cost delivered was $3227, while the entire expense of preparing, dismantling the old, and erecting the new battery-frames was $557. The total cost per pound of material erected was 7.07 cents. The stamps were dismantled 20 at a time, so that only 3 days of crushing time was lost for each 20-stamp section.

The use of cast-iron in battery-frames is old, of course. It is customary at Bendigo, in Australia, where in 1890 I saw an iron-framed stamp-mill (the Garden Gully United) that had then been in use for fully 20 years. It is generally supposed that a wooden frame, being less rigid, takes the vibration better than iron, which, on the contrary, is supposed to become crystalline and then brittle, from 'fatigue.' A. B. Foote considers that the use of steel in the new mill has been justified, but he advocates a minimum of rivets and heavier shapes, say, a post of two H-beams.

Here I may mention the cam invented by Arthur B. Foote, the present superintendent. It is based on the idea of starting from rest with a uniformly accelerated velocity. While in use, it is impossible for the hand when placed on the tappet to feel the cam strike the tap-

pet. even when the stamp is dropping 107 times per minute. The adoption of this cam has lessened breakages and fatigue of the battery-frame. Thus in the old mill 11 cam-shafts were broken both in 1912 and in 1913, but only 2 were broken in the last 12 months. It is economical to run the stamp-mill fast even at the expense of breakages, if not excessive. In other words, there is an economic ratio. In one year the North Star mill has broken 24 cams, 10 tappets, and 11 cam-shafts.

Of the stamp-mill product, 60% is classified as sand, 40% as slime. The tube-mill formerly in the Central plant was 20 ft. long; it was cut in two, making two short mills, one for each plant. After three years, $22,000 in amalgam was taken out of the one tube-mill when it was bisected, after the treatment of 5400 tons of concentrate.

By way of comparison the following figures are interesting:

INTERIOR OF THE CENTRAL MILL OF THE NORTH STAR MINES.

In both mills 78% of the total extraction is effected by amalgamation. The apron-plates are 20 ft. long. Dodd buddles, 9 of them, are used to separate the concentrate. These machines are not commendable, for their maximum velocity is at the periphery, where the final separation is made. A tube-mill (4 by 10 ft.) is used to re-grind the sulphide concentrate, which then passes over small amalgamating tables, which extract 30% of the gold. The residue joins the other mill-tailing on its way to the cyanide annex, about 300 yards down the valley. Here the tailing passes through

4 Merrill classifiers,
6 thickeners,
Another Dorr thickener,
6 (100 tons each) sand-vats (6 by 25 ft.),
4 air-lift agitators** for slime agitation,
2 Oliver filters,
2 Merrill presses, one in use at a time.

**Built before the Pachuca was invented.

Year.	Weight of stamp.	Number of drops.	Duty, tons.	Screen, mesh.
1895	850	84	1.6	30
1915	1050	106	3.8	25

	Concentrate, %	Consumption of mercury per ton of ore, dwt.	Wear of screen, days.
1895	3	14½	24
1915	2	5	21

The screen of perforated tin-plate used 20 years ago has been replaced by punched steel with holes 0.04 in. diameter or 288 holes per square inch.

The Oliver filter is a Grass Valley product, for it was invented by E. L. Oliver while he was employed at the North Star. It is essentially a vacuum-filter on the outer surface of a drum. The drum is of 10-ft. diameter, with a face 7 ft. wide. This is covered first with 2-in. grooved staves or drainage strips, then a wire-screen, then burlap, finally canvas. The vacuum-pipes radiate

to the under side of this covering from a central nest of pipes. Of the total circumference, one part in 24 is blown, the rest is sucked, forming a cake of slime. This cake is removed automatically by a scraper and spray of water after it has been loosened or blistered by the air blown from the pipe under a strip across the face of the drum representing, as I have said, $^1/_{24}$ of its entire circumference. The filter is excellent for slime not requiring lengthy washing.

Two filters, with their line-shaft and vacuum-pump, use 8 hp. Air required for blowing is at the rate of 4 cu. ft. per minute, at a pressure of 18 lb. per square inch. The covers last for 8 months; the cost of re-covering is $25, including labor; each filter treating 800 tons of slime per month. The cost of re-piping is $30, but it is necessary only once in four years. The total cost of re-covering and re-piping is ½c. per ton only. The area of the filter is 220 square feet.

At the Empire mine, Mr. Starr showed me the new hoisting plant. It is a Wellman-Seaver-Morgan electrical single-reduction hoist, operated by a 500-hp. motor, which is worked 75% overload at starting, and can be worked at 100%. The drums have a capacity for 8000 ft. of rope, to raise 4 tons of ore at the rate of 1200 ft. per minute. Construction is of steel throughout. Wuest herring-bone gear is used. The brake is applied over a 12-in. drum-surface. Automatic arrangements to prevent over-winding are electrical. If the engineer fails to keep the lever under control, the power is cut-off automatically and the brakes applied. As the skip goes into tipplers, two electric devices give warning by a bell and lights; if over-wound two feet, another contrivance shuts off the power and applies the brakes.

The old mill of 40 stamps has been replaced successively by 60 new stamps, each of which weighs 1350 lb. and crushes 4.82 tons per day, as against the duty of 3.8 performed by the old 1040-lb. stamps. The timber foundations have been replaced by concrete. Some of the old timbers, which had served for 30 years, were solid throughout, but most of them had rotted at the edges. A separate motor drives each 10 stamps. A Tyler wire-screen of 27 mesh is used, giving 60% of a 200-mesh product. After the amalgamating tables, 53 in. wide and 13 ft. long, come twenty-four 6-ft. Frue vanners.

The tailing from the stamp-mill passes through a 12-in. terra-cotta pipe laid on a 2½% gradient to the cyanide annex. This terra-cotta pipe has been in use for 4½ years, but the glaze has not been worn off yet.

The concentrate, at the rate of 8 tons daily, assaying $140 to $160 per ton, is moved along a gravity tramway to the cyanide annex, where it is discharged into a bin, thence into a truck, weighed, and then discharged into a machine like a Blaisdell excavator, which feeds it into a tube-mill, 3½ by 12 ft., of Allis-Chalmers make. After being re-ground this sulphide product goes to three Devereux agitators, having a 4-blade propeller, 38 in. diameter, making 110 rev. per minute. Each agitator requires 3¼ hp. only. Before it is started the water in the vat (of 18 tons capacity, concentrate only) is drained off and the vat filled with a solution containing 0.10% cyanide. Then follows agitation and decantation: this process being repeated until the necessary treatment and wash is obtained. The residue contains only 5% of the assay-value. When the stamp-mill tailing reaches the cyanide annex it is doctored with lime (4 lb. per ton) in the form of a paste or emulsion as it passes to 2 Merrill classifiers or settling-cones. From there it goes to 4 clarifiers (24-ft. diam. and 22 ft. deep) or dewatering tanks. Thence to 4 Pachuca agitators, discharging to 3 Oliver filters. The sand is leached in 6 vats, each 24-ft. diam. and 10 ft. deep.

The concentrate represents 2% of the crude ore; the stamp-mill tailing contains $1.75 in gold; the final discard below the cyanide annex assays 21 cents. The total extraction is 97%. When as much as that is won, it is well not to make any change.

The cyanide treatment of the stamp-mill tailing was started only 4½ years ago; before that canvas tables were in use, the resulting concentrate being shipped to the Selby smelter.

Oil Exhibits at the Exposition

These are in the Palace of Mines and Metallurgy. That of the Union Oil Co. of California includes four huge dinosaurs, which are said to have existed during the period when oil was formed. These are shown crawling over the front of the booth. A cyclorama shows a scenic representation of a typical oilfield. The geological exhibit contains some rare and costly fossil specimens collected from various parts of California, Texas, Wyoming, Oklahoma, Arizona, Mexico, Panama, Utah, and Louisiana. There are also lubricating and refined oils and asphalts shown.

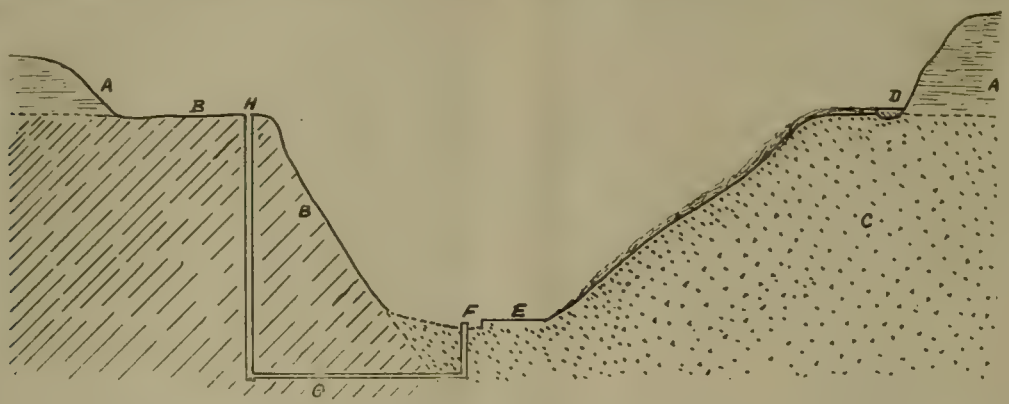
The Standard Oil Co. of California has a reproduction of the famous Section 36 in the Midway field, California, showing the strata to a depth of 3000 ft. On the surface are pumps, tanks, sumps, and employees' quarters. A panoramic reproduction of the field near Taft, California, is in operation. Various methods of transportation, a tank-steamer, tank-car, and motor and horse-drawn trucks, are shown in model. The displays include asphaltum products as applied to highway construction, illuminating and lubricating oils, candles and paraffine products, floor-polishes, and lamps and stoves. The exhibit space is surrounded by oil-derricks bearing placards of the production of various sections of the fields.

AN EXPOSED TRAIN OF GEARS, an unprotected revolving bolt head, set-screw, feather or spline, an open keyway on a shaft, and the like, are all well-recognized dangers. Yet few indeed are the machines where these are all absent. The means to be employed to prevent accidents from these causes are two in number: First, eliminate so far as possible angular projections on revolving or moving parts; for example replace ordinary square-head setscrews with those of the hollow variety which screw down flush. Second, guard or protect the moving parts of the machine.

Kaolin

By WILSON W. HUGHES

The term 'clay' covers a wide range of material. Clays differ in origin, mineral and chemical characteristics; they all exhibit plasticity when wet and become hard when dried naturally or artificially. They have been described as "Heterogeneous aggregates of hydrous or anhydrous aluminous silicates, free silicates, and ever-varying quantities of free iron oxides, calcium and magnesium carbonates, all in a finely comminuted condition." The ordinary clays used for brick, tiling, drain-pipes, terra-cotta, etc., are found in abundance in the United States, but high-grade white clays, known as kaolin or china-clay, have not as yet been developed in sufficient quantity to keep pace with their use in the manufacture of porcelain, china, and paper. The following figures, taken from the 'Mineral Resources of the United States' speak for themselves.



CHINA-CLAY PIT (section)

AA. Overburden.
BB. Undecomposed rock.
CC. Decomposed rock.
D. Washing water.
E. Sand-catch.
F. Shaft down which clay-bearing water drops to (G).
G. Level connected with (H).
H. Pump-shaft where clay-water is pumped to surface and sent to settling-pits.

KAOLIN MINED AND SOLD IN THE UNITED STATES

	Short tons.	Value.
1905-1913 (china-clay)	320,440	$2,427,023
1905-1913 (paper-clay)	795,997	3,607,408
Total	1,116,437	$6,034,431

KAOLIN IMPORTED INTO THE UNITED STATES

	Short tons.	Value.
1907-1913 (both kinds)	1,732,150	$10,526,157

Therefore the imports for 7 years exceeded the production of 9 years by 606,713 tons, valued at $4,491,726. The actual difference in favor of the imports for 1913, the last year on which figures are available, was 113,495 tons, valued at $818,559. That this country is now dependent on Europe for 60% of the kaolin used here is the more interesting because English potters imported it from North Carolina nearly 200 years ago for use in the manufacture of chinaware. Now the exports of kaolin from the west of England closely approach the million-ton mark, if not exceeding it, every year.

Barber* says, in regard to the export of kaolin from Carolina: "It was obtained in the Smoky mountains by the Cherokee Indians who called it *unakah* (meaning white) which was their name for the Smokies. It is still called 'unakah' in Mitchell county. English potters were using china-clay from this country previous to the middle of the last century (1700)."

In 1744 a patent was granted in Great Britain to Ed. Heylyn and Thos. Frye for the manufacture of chinaware. In their specification they state that the material used in their invention "is an earth the product of the Cherokee nation in America, called by the natives 'unakah,'" * * * In 1878-79 a Mr. Goss of Stoke-on-Trent in a series of notes states: "This unakah, the produce of the Cherokee nation, is decomposed granitic rock, the earth or clay resulting from the washing of the rock being the decomposed feldspar of that rock. It is curious that it should have been imported from among the Cherokees when we had mountains of it so near as Cornwall, unknown, however, until Cookworthy discovered them in 1768" * * * The Cookworthy referred to was familiar with American clays as early as 1745, for he is quoted as writing in that year: "I have lately with me the person that hath discovered the china-earth. He had samples of the chinaware of their making. T'was found in the back of Virginia where he was in quest of mines. Discovered both petunze and kaulin. 'Tis the latter earth he says is the essential thing. He has gone for a

*'Pottery and Porcelain of the United States.'

cargo of it, having bought the whole country from the Indians where it rises. * * *" Josiah Wedgewood also imported china-clays from both Carolina and Florida into England.

The origin of the word 'kaolin' as used to designate the high-grade white clays of commerce, was due to the mistaken idea that the clay used by the Chinese in the manufacture of porcelain was called *kao-ling* (meaning high ridge), from the district in which it was obtained. This however was not the case. T'ang Ying, director of the Imperial factory at Ching-te-chin in 1743 states: "Those of pure white color and fine texture are used in the manufacture of bowls and vases of egg-shell pure white, and white and blue porcelain. Besides, there are several other kinds of earth called *kao-ling*, *yu-hung*, and *chien-tan*, all produced within the limits of Jaochow. These are only used for mixing with the first named, or in the fabrication of coarser ware." The name now, however, is universally accepted as signifying the purest varieties of clay known. They consist almost exclusively of alumina silicate and water, and are an impure form of the mineral kaolinite, which is represented by the formula $H_4Al_2Si_2O_9$. They exhibit less plasticity than other clays, becoming pulverulent and of a white or creamy color when dry.

[Samples of the materials used by the Chinese were first sent to Europe by Pere d' Entrecolles, a missionary in that district. He may possibly have applied the name *kao-ling* to all the numerous varieties of material for which the Chinese had distinctive names.—EDITOR.]

Their chemical composition is shown in the following table.

Constituent.	Natural material from Ching-te-chin.	From Ching-te-chin used for blue ware.	English (Cornish) china-clay.	French clay, St. Yrieux.	Hockessin, Delaware.	Kaolinite.
Silica	73.55	73.55	73.57	46.68	48.73	43.10
Alumina	21.09	18.98	16.47	36.92	37.02	36.92
Ferric oxide	...	....	0.27	....	0.79	....
Lime	2.55	1.58	1.17	....	0.16	....
Magnesia	0.15	1.08	0.21	0.52	0.11	....
Potash	...	0.46	5.84	0.58	0.41	....
Soda	...	2.09		....	0.04	....
Water	2.62	1.96	2.45	13.13	12.83	20.07

All clays are of secondary origin. They are the result of the breaking up of rocks and minerals, with consequent aggregation and concentration of the less soluble residue. Silicate of alumina, being one of the most insoluble substances known, is the chief constituent of such residues. Such an aggregation, if remaining on the spot where the disintegration of the original rocks took place, is termed a 'residual deposit', but if it is transported by water or glacial action to another locality, it is called a 'transported clay.'

Kaolin deposits occur almost invariably as residual clays. They are the product of the disintegration of feldspathic rocks, in which the decomposition of the feldspar plays the most important part. The term used to describe the action is derived from the product, and the word kaolinization has become part of the English language. The cause of kaolinization has been ascribed to various agencies, atmospheric and hydro-thermal, but I hold no brief for either contention or their sub-divisions. Whatever the original cause, the fact remains that the action on the feldspar may be shown as follows:

	SiO_2	Al_2O_3	K_2O	H_2O	Total
	%	%	%	%	%
Orthoclase	64.56	18.29	16.85	...	100.00
Loses	43.24	....	16.85	...	60.09
					39.91
Takes up	...	....	....	6.45	6.45
Kaolinite	21.23	18.29	....	6.45	46.36

This alteration is naturally of varying degrees of intensity in any one place, the result is that any kaolin deposit is of irregular grade, and consists of an intimate mixture of quartz, undecomposed feldspar, mica, and other minerals in addition to the aluminum silicate contents. Partly-altered country-rock is also found. In the china-clay deposits of the west of England this is known as china-stone or petunze. Such deposits may be of any width and thickness and are usually covered by an overburden of subsoil, this also varies in thickness, and the cost of its removal has an important bearing on the economic value of the deposit.

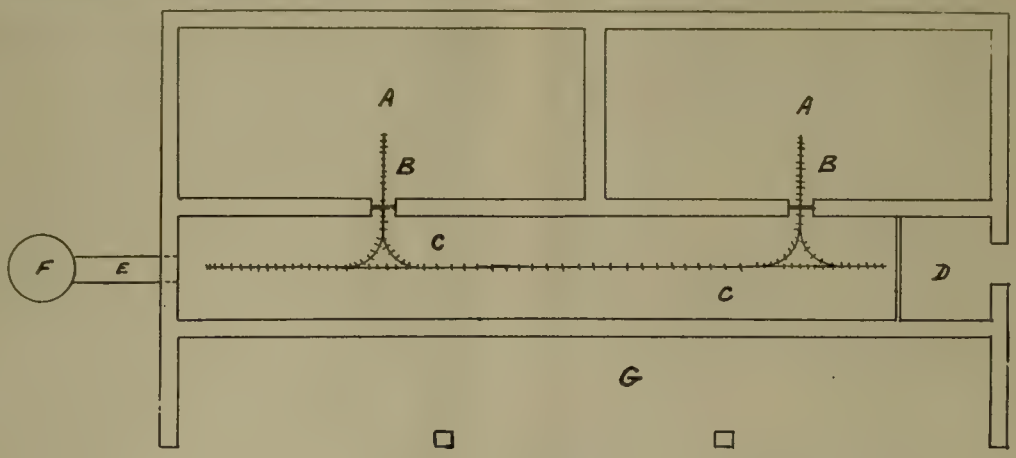
From the foregoing it can be seen that deposits of kaolin should be looked for in districts of highly feldspathic rocks, such as granite and gneiss. They may be expected to lie in depressions within such areas. Their presence is shown by the finding in marshy ground of a white clayey mud. Districts of low humidity are not so likely to contain them. When clay has been found, a weighed sample should be washed and the residue should not exceed 5.25 parts by weight to one of dried clay. The clay itself should not leave any residue on a 120-mesh screen, after brushing with a soft brush. The chemical analysis should approximate to one of the analyses given in the table above. As the refractory properties of clays seem to depend largely on the presence of alumina and silica, and freedom from constituents that are fusible or would combine with others to form a flux, it is necessary that a good commercial clay should be low in iron oxide and alkalies such as soda, potash, lime, and magnesia. Although iron is not possibly so detrimental as a flux, it is fatal to the ware, causing black spots on firing. Potash produces an incipient vitrification, which causes the ware to ring like a bell on striking. Therefore the presence of these minerals in large proportion unfits the clay for fine pottery work. At the same time it might be useful for other purposes. On firing a sample of the clay, it should be white, non-vitreous, free from specks, hard, and compact. Very often clay is colored by organic matter, but this color disappears on the application of heat.

After finding a deposit containing such a clay it is easily prospected by drilling or sinking pits to deter-

mine its area, average grade, and thickness. For the economic working of kaolin pits, and the production of a commercial clay, two things are essential: one is a good supply of water, and the other is ready transportation to commercial centres or the sea-coast. Assuming that the clay is found and that there is a plentiful supply of water, the working of the clay consists essentially in the washing of the decomposed rock by means of a stream of water. The water takes up in suspension the fine clay particles, leaving behind the associated quartz, unaltered feldspar, etc. The clay-bearing stream is then conducted over shallow troughs where the mica is deposited, and thence to settling-pits in which it drops its burden of clay, being returned to the deposit to be used over again.

In actual practice the water is conveyed to the side of the clay pit and allowed to run down the face. The clay start with, and as the clay settles on the bottom and accumulates in the pit the holes in the launder allow the stream always to deliver at the lowest point possible. The pits are usually circular and may be 20 ft. deep. In these the water drops its burden of clay, the clean effluent being returned to the deposit to be used again. The water-cycle is continuous.

When the clay rises in any pit to the point where settlement is slight, the stream is turned off and the clay allowed to subside. It is then run into other pits where further settlement ensues, until it becomes a fairly stiff clay. From these it is transferred by means of cars onto a drying-floor. The 'drys' or floors consist of fire-clay tiling, covering a number of parallel flues. The flues are connected at one end with the fire-grates and at the other to a brick stack. They are about 14 in. wide and the tiles are sufficiently wide to span them from



'DRY' FOR CHINA-CLAY (plan)

AA. Settling-tanks.

G. Store for dried clay.

mixture is raked in the path of the stream, so as to obtain as thick a mud as is possible. The stream is passed into wooden bins with a perforated bottom in which the quartz and heavy residue is caught. The water, carrying the clay and mica in suspension, passes through the coarse sandy residue, and is then pumped into launders through which it passes to the mica-traps. These traps are shallow troughs in which the velocity of the clay liquid is reduced, and the depth of the stream diminished. The mica settles and is retained, the suspended clay passing forward to the settling-pits. These pits may be close to the works, but in many cases the clay in suspension is carried through pipes or launders for long distances. This procedure is adopted when the deposit is at a distance from the railroad, as it is then possible to settle and dry the clay at the point where fuel and transportation are readily obtained. The water with its clay burden passes into the settling-pits through vertical box-launders, perforated with holes. The delivery is therefore always at the bottom of the pit to centre to centre, having a thickness of 5 to 6 in. over the firing end and reducing to 2 or 3 in. at the other end. These 'drys' vary in length and width, but are usually 150 to 200 ft. long, and up to 15 ft. wide. The clay is run upon this to a depth of 9 to 12 inches at the fire end and about 6 in. at the stack end. The charge at the fire end will dry in about a day, but the other end may take three days. When the charge becomes plastic it is cut into rectangular blocks. This assists the drying process, and also is of help in shoveling the dried clay. When dry the clay is thrown off the side of the 'dry' into a paved space that runs the whole length of the floor. Here it is packed into barrels for export or lies in bulk awaiting shipment. Where possible, the railroad track adjoins the side of the 'dry' so that cars can be loaded direct. The fuel used for heating purposes is hard coal. A bituminous coal is detrimental, as the clay is likely to be smutted by it. The Cornish drying system as outlined above is, I believe, capable of much improvement. A large amount of the moisture in the clay percolates

through the porous tile flooring and is converted into steam in the flues, as is readily perceived from the white cloud of steam that escapes from the stack. This surely cannot be the most economical method of evaporation.

The limits of this article will not allow of entering into these points of detail. It is many years since I have visited a clay works; the data I have may be slightly out of date, but the system as outlined is, I am told, in use at the present time.

China-clay is used principally in the manufacture of porcelain or china, and paper. China, or porcelain, is a mixture of kaolin with various substances; the mixture must be plastic enough to be worked into forms for ware. When burned it fuses sufficiently to give it the proper strength. The subject of porcelain-making is a complex one, and the reader is referred to the treatises on the subject for further details. Paper-clay must usually be pure white, but that of poor color may be re-washed and used. Wall-paper manufacturers employ it to give a smooth satiny finish. It is applied in the form of a thin size, and then polished between brushes. As purity of color is essential for this purpose, only the finest clay can be used. In the manufacture of other papers it is used to give body and weight. Heavy wrapping papers contain about 5% china-clay.

The kaolin-producing states of this country are Delaware, Georgia, North and South Carolina, Missouri, and Pennsylvania. Discoveries have been noted in 17 counties of California, but, with the exception of the Carbondale deposits, in Amador county, they do not seem to have been developed seriously. Kaolin from these beds has the following composition:

	%			%	
Silica	48.9 to	60.00	Magnesia	trace to	0.09
Alumina	30.29	38.18	Alkalies	1.02	2.32
Ferric oxide	0.53	2.40	Water	8.05	8.95
Lime	trace	0.50			

The average composition therefore approximates that of the Delaware clays. The production from other western states is so small as to be negligible. I have not dealt with the cost of production in this country, as data on that point are difficult to obtain, and any figures would have a local value only. So much depends on situation, labor, transport, availability of fuel, etc., but it may be briefly estimated that the value of clay ranges from $3.66 to $7.50 per ton and that with favorable conditions it ought to be produced for $1.55 to $3.25. This article has been compiled from notes extending over a period of years, supplemented by personal observation. I have not always been able to find the authority for some of the statements made, and if I have plagiarized in any item it is unintentional on my part.

Solidification of various hot molten materials is most commonly carried out with water from any natural source of available temperature, but is better controlled by mechanically cooled water or brine, as, for example, in the manufacture of candles, wherever the speed of cooling and the constancy of the rate contributes to cost reduction or to improvement of quality of product.

Zinc Smelters in United States

In an address made by Paul E. Ewert before a meeting of zinc-ore producers recently held at Joplin, Missouri, the statement was made that of 120,000 zinc retorts in the United States, 87,000 are owned by five companies, which the attorney designated as the 'Big Five,' though on just what basis is not clear, as two companies not included are larger than one of those included in the nefarious group. Presumably the inference is that the five companies have combined to control the spelter market, but this overlooks the important fact that the keenest competition exists between these companies and the relations of some of them are far from cordial. As a matter of fact the smelting companies are said to be welcoming the Federal investigation of the zinc industry as affording an opportunity to demonstrate before an official body that there is not and never has been a combination of the smelters. As the list of smelters prepared by Mr. Ewert is of much interest, we give it below without alteration, except to correct some of the more obvious errors. It is impossible to check the number of retorts given, since the recent rise in the price of spelter has brought about rapid changes in the effort to increase smelting capacity as quickly as possible. Plants that had been closed down have been re-opened and new construction rushed to completion, so that complete accuracy is difficult to obtain.

The "Big Five" consists of the following: The New Jersey Zinc Co., the American Metal Co., Vogelstein & Co., Beer, Sondheimer & Co., and Granby Mining & Smelting Company.

Total retorts in the United States	120,000
Total retorts owned or controlled by the "Big Five"	87,000

The New Jersey Zinc Company

The New Jersey Zinc Co. owns a controlling interest in all of its smelters. It has an absolute monopoly of the zinc oxide output in the United States. It manufactures between 80 to 90% of the zinc oxide of the country. It also is a producer of high-grade spelter, making the highest-grade spelter produced in the United States. It alone produces 20% of the total spelter output of the United States. It owns and controls the following smelters:

	Retorts.
Mineral Point Zinc Co., Mineral Point, Wisconsin	3,920
Prime Western Smelting Co., Gas City, Kansas	4,768
New Jersey Zinc Co., Bethlehem and Palmerton, Pa	5,760
(Now building)	3,456
Mineral Point Zinc Co., Depue, Illinois	9,080
(Now building)	2,280
Tulsa Fuel & Manufacturing Co., Collinsville, Oklahoma	6,232
Bertha Mineral Co., Pulaski, Virginia	1,400
Total retorts owned or controlled by the New Jersey Zinc Co.	36,896

The American Metal Company

The American Metal Co. is commonly supposed to be a branch of the German Smelter Trust. Much of its stock is owned by the Metallurgical Company of America. Next to the New Jersey Zinc Company, it is the biggest

factor in the American smelting industry. It owns the stock or controls the output of the following smelters:

	Retorts.
Bartlesville Zinc Co., Bartlesville, Oklahoma	5,184
Bartlesville Zinc Co., Collinsville, Oklahoma	8,064
Lanyon Starr Co., Bartlesville, Oklahoma	3,456
American Zinc & Chemical Co., Langeloth, Pennsylvania (now building)	3,456
Total retorts owned or controlled by the American Metal Co.	20,160

VOGELSTEIN & COMPANY

Vogelstein & Co. owns or controls the output of the following smelters:

La Harpe Spelter Co., La Harpe, Kansas	1,856
American Zinc Lead & Smelting Co. (51% of this company is held in the vaults of Hayden-Stone & Co., bankers, Boston, for Vogelstein interests).	
Deering, Kansas	3,840
Caney, Kansas	3,648
American Zinc Co., Hillsboro, Illinois	3,200
(Now building)	800
Total retorts owned or controlled by Vogelstein & Co.	13,344

GRASSELLI CHEMICAL COMPANY

Clarksburg, West Virginia	5,760
Meadowbrook, West Virginia	6,912
Total	12,672

(Buyer of low-grade ore. Manufacturer of acid at Grasselli, Indiana, shipping residue to Virginia to make low-grade spelter.)

BEER, SONDHEIMER & COMPANY

Beer, Sondheimer & Co. is commonly believed to be one of the subsidiary companies of the European Smelter Trust. It owns only one smelter in its own name, but has a majority of the stock or controls the output of three smelters, as follows:

National Zinc Co., Bartlesville, Oklahoma	4,470
National Zinc Co., Springfield, Illinois	3,200
Altoona Zinc Smelting Co., Altoona, Kansas	3,960
Total retorts owned or controlled by Beer, Sondheimer & Co.	11,630

HEGELER ZINC COMPANY

Hegeler Zinc Co., Danville, Illinois	3,600
Matthiesson & Hegeler, La Salle, Illinois	6,168
Total	9,768

(Uses its own spelter for the manufacturing of sheet zinc.)

GRANBY MINING & SMELTING COMPANY

Granby Mining & Smelting Co. owns or controls the output of the following smelters:

Smelter, Neodesha, Kansas	3,840
Smelter, East St. Louis, Missouri (now building)	3,240
Total retorts owned or controlled by Granby Mining & Smelting Co.	7,080

EDGAR ZINC COMPANY

Edgar Zinc Co., St. Louis, Missouri	2,000
Cherryvale, Kansas	4,800
Total	6,800

(Eighty per cent of stock owned by American Steel & Wire Co. of the U. S. Steel Corporation. Buys only for spelter used by the Steel Corporation.)

ILLINOIS ZINC COMPANY

Peru, Illinois	4,640

(Purchaser of high grade blende only, which it manufactures into sheet zinc.)

TULSA SPELTER COMPANY

Sand Springs, Oklahoma	4,000

(Works supposed to be backed by United States Zinc Co.)

CLARKSBURG ZINC COMPANY

Clarksburg, West Virginia	2,736

UNITED STATES ZINC COMPANY

Pueblo, Colorado	1,920

(Not in Joplin market. Is part of lead monopoly, smelting zinc-lead ores only.)

ROBERT LANYON ZINC & ACID COMPANY

Hillsboro, Illinois	1,840

COLLINSVILLE ZINC SMELTING COMPANY

Collinsville, Illinois	1,536

(Now owned by certain stockholders of the Picher Lead Co. of Joplin, Missouri.)

CHANUTE ZINC COMPANY

Chanute, Kansas	1,280

SANDOVAL ZINC COMPANY

Sandoval, Illinois	996

(Purchaser of zinc dross only.)

MISSOURI ZINC COMPANY

Beckemeyer, Illinois	192

The Transvaal at the Exposition

Simple yet attractive is the display of the Transvaal Chamber of Mines in the Palace of Mines and Metallurgy at the Exposition at San Francisco. In the centre of the booth is a high obelisk, divided into sections showing the relation of the Rand to the rest of the world's gold output, as follows: Rand, 40%; United States, 19.4%; Australasia, 11.3%; Russia, 5.5%; Mexico, 4.5%; Rhodesia, 3.1%; Canada, 2.9%; India, 2.7%; West Africa, 1.8%; and all other countries 8.8%. On each side of the obelisk is a large golden sphere. One represents $180,812,720, the other $271,320,720, the respective gold yields of the Rand and the rest of the world in 1913. A case contains a model of the surface plant at the Modder B. mine. The 90 stamps on this mine in 1914 crushed 440,000 tons of ore. Other cases show the typical Rand rock and ore. Miners and others are able to better understand the small amount of gold in one ton of ore by the exhibit of a cube, 12 cu. ft., representing one short ton of Rand ore. On top of this is a small gold cube equal to 6.84 dwt., the average value in 1913. The yield was $6.54, and residue averaged 30c. per ton. Gold output of the Rand in April was 744,080 oz. valued at £3,160,651. For the first four months of 1915 the yield is 240,528 oz. more than in 1914.

FLUORSPAR PRODUCTION of the United States in 1914 amounted to 95,116 short tons, worth $570,041. In 1913 the total was 115,580 tons, valued at $736,286. The market for this mineral depends on the steel industry.

Cyanide Plant at Kushikino, Japan

The most up-to-date cyanide plant in Japan is that of the Kushikino gold mine, Kagoshima-Ken. It is not only new in its construction, but is the first mill to employ the all-sliming process. All the other gold mines in Japan use the percolation or semi-sliming process.

The Kushikino mine had been worked for a long time by crude methods when the Mitsui Mining Co., one of the most important corporations in Japan, acquired it in 1906, forming a concession by gathering together a number of small properties. For some years the company carried on only exploration and development work underground. When the existence of a sufficient amount of workable ore had been proved, it was decided that a mill of modern design should be built. Meantime the company had sent K. Hasegawa to America to study the best process of treating the ore. He found the methods prevailing at Goldfield, Nevada, best suited for the requirements. It was therefore decided to order all the machinery from the Allis-Chalmers company, Milwaukee, which designed and erected the plant of the Goldfield Consolidated. The Kushikino mill was completed in the fall of 1913, and the work has since proceeded smoothly and satisfactorily under the management of Mr. Hasegawa.

The mill is well placed on a hillside only half a mile distant from the railroad station, called Kushikino. It is 23 miles west from Kagoshima city, and only a mile from the sea-coast on the west. The mill, both inside and out, much resembles that of the Goldfield Consolidated, only on a diminutive scale. All the machinery is of nearly the same pattern and about the same arrangement. There are 40 stamps, each weighing 1250 lb., with a capacity of 6 tons per head. The power is obtained from a 318-hp. suction gas-engine, which drives four 50-kw. electric generators. The fuel used is lump coke made at the Miike coal mines, belonging to the same company. The cost of power is only 0.6 cents per kilowatt-hour. The pebbles used in the tube-mills come from Denmark, the consumption being 100 lb. per day. For the lining of No. 1 and No. 2 tube-mills, silex is used. This comes from France, and costs $200 for 25 cu. yd., the wear being 1 inch in six months. In No. 3 tube-mill cast-iron lining has been tried recently.

As the ore contains 10 to 16 times as much silver as gold, rather strong solution is used, the strength in the agitation-vats being 0.3% cyanide. The consumption of cyanide is said to be 3 lb. per ton of ore. The cyanide averages 98 to 100%, and comes from England.

The zinc-dust used is manufactured in Amuda, near the Miike coal mine, where the same company established a large zinc-smelting works in 1913. The consumption of dust is said to be 0.25 lb. per ton of ore. The ore is low-grade, the average content of gold being $6.25 per short ton and 3.45 oz. silver. The extraction made is 87% of the gold and 84% of the silver.

The production of gold and silver in this mill in the last four months was:

	Gold, Oz.	Silver, Oz.
November 1914	1,554	15,579
December "	1,301	16,993
January 1915	1,040	9,410
February "	1,443	12,442

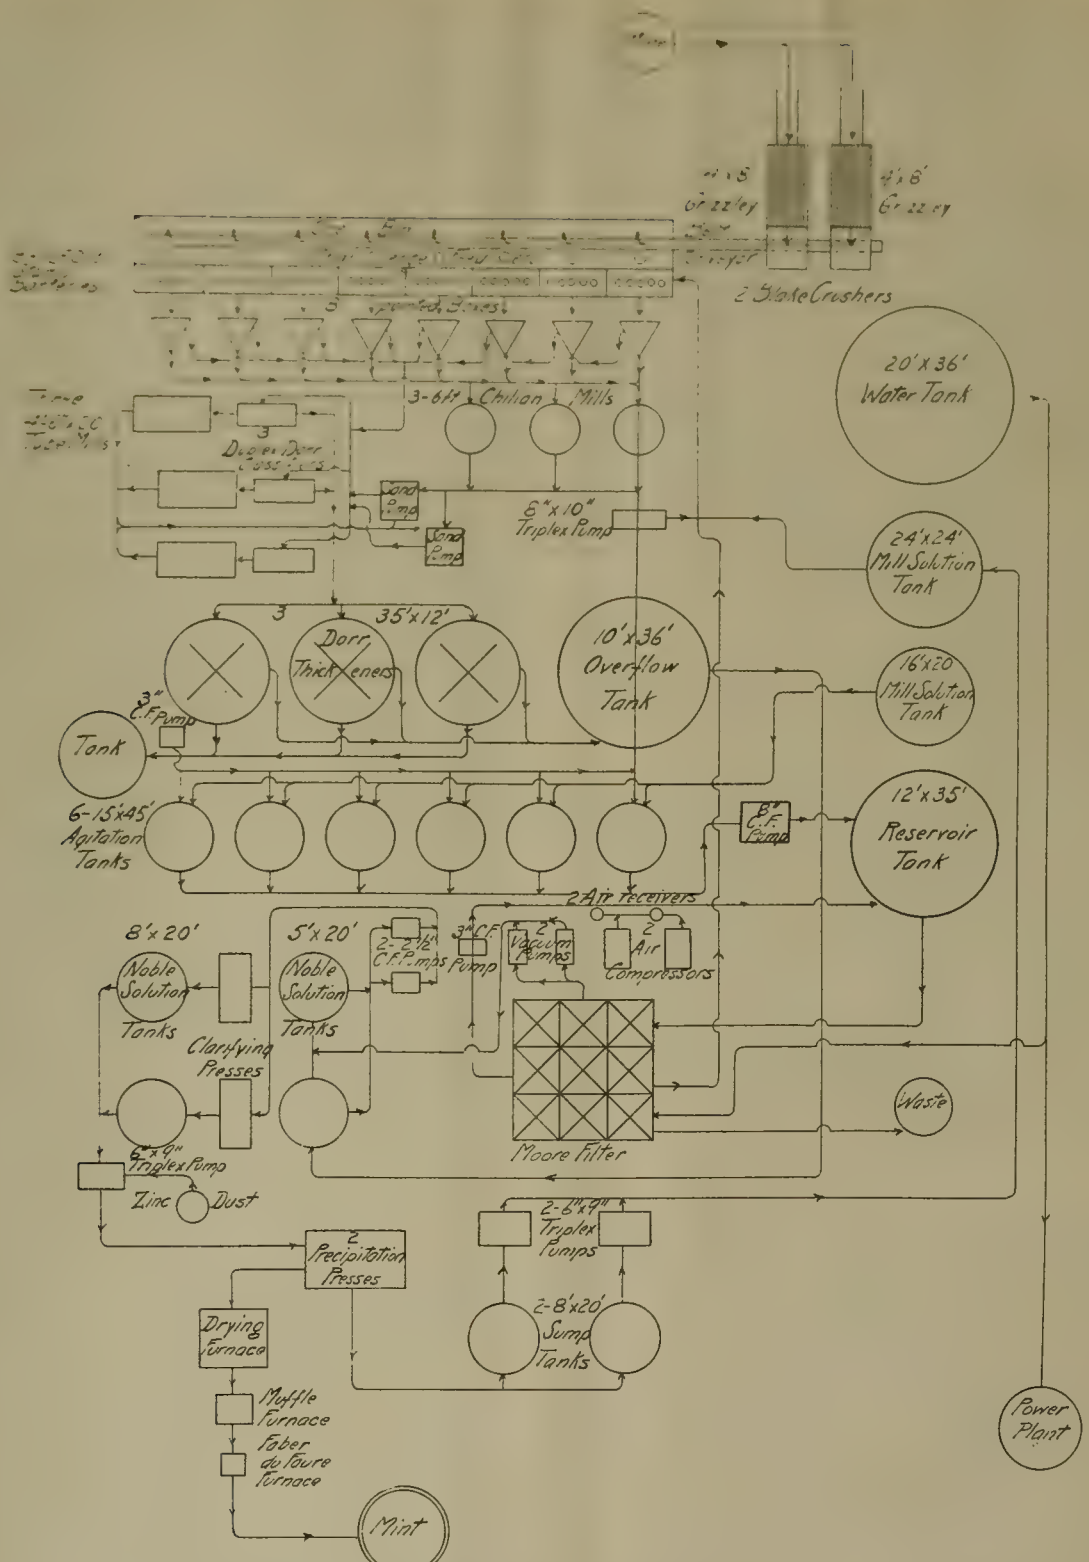
The production at Kushikino is nearly equal to that of the Sado mine, which stands second in gold production in Japan, Hidachi ranking first. The last is a custom smelter and smelts gold-bearing quartz from several mines all over the country. The Kushikino mill is only supplied with ore from the mines owned by the company in its vicinity.

The ore handled by the mill comes mainly from the Nishiyama mine. The company has another mine called Hajima, which is now mostly in the exploration and development stage. The Nishiyama mine is three miles from the mill, and the ore is brought down on a surface tramway in cars drawn by horses. In the mine there is only one large vein, striking nearly east to west with a dip of 50 to 70° south. The country-rock is andesite, which has intruded Tertiary sandstones and tuffs. The thickness of the vein varies from 3 to 50 ft., averaging 15 to 20 feet. It has already been followed for 7000 ft. along its strike by an adit-level. The vein was well explored above the adit, and three different shoots of good ore were found. Each of these extends for 1000 ft. in length, though it is not yet known to what depth the ore may persist. A shaft has been sunk on the vein 120 ft. below the adit. Sinking is now hindered by a flow of 300 cu. ft. of water per minute. With the present capacity of the mill, it is not necessary to push work below the adit, since there is enough ore in reserve ready for stoping. The ore reserve is calculated at more than 1,000,000 tons with an average gold content of $5.50 per ton.

Another mine belonging to this company, the Hajima mine, is situated on the opposite side, at the distance of two miles from the mill and nearer the coast. There are a number of veins, though none is large; and they have been well explored, showing ore of the same quality as at Nishiyama. After the completion of an aerial rope-way now planned, a considerable tonnage of ore from the Hajima will be brought to the mill for treatment. The Kushikino gold mine, with its new mill and two mines, is making good profits and has demonstrated that modern methods of mining and milling are the most advantageous for work in Japan. The future of Kushikino is promising.

MINERAL EXPORTS of Chile decreased from $126,988,673 in 1913 to $93,818,408 in 1914. This was due to the War, which upset the nitrate industry. On March 25 the price was $1.54 per 101.4 pounds.

BARYTE PRODUCTION of the United States in 1914 was 34,315 tons, valued at $447,358. Most of this is used in white paint.



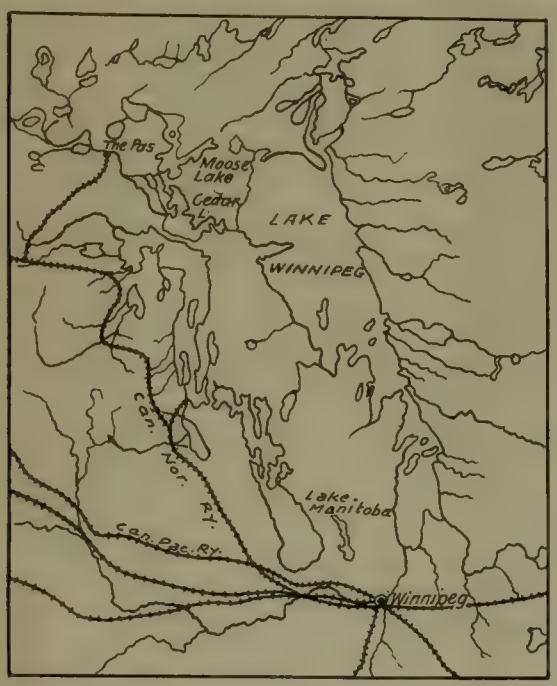
FLOW-SHEET OF THE KUSHIKINO MILL.

Beaver Lake District, Saskatchewan

By CHARLES A. BANKS

Beaver lake, around the north shore of which there has been considerable staking of claims, is about 20 miles long. It contains a number of small islands. It is situated in northern Saskatchewan; within about 12 miles of the western boundary of Manitoba. The nearest railway connection is the small town of Le Pas. This place is in northwest Manitoba, on the south bank of the Saskatchewan river, where the latter is crossed by the Canadian Northern railroad.

The population of Le Pas, including its large number of transient railway men, is about 2000. It is a typical



A PART OF SASKATCHEWAN.

Canadian frontier town, boasting of one well patronized hotel, and two moving-picture theatres. The recent real-estate boom is probably responsible for the scattered appearance of the town. Ill-fed 'huskies'—the dogs of the North—are to be seen prowling around most of the streets, which were, at the time of my visit, in a hopeless state of mud and disorder. Le Pas is reached by a tri-weekly service from Prince Albert or Winnipeg. Either route occupies about 24 hours. Beaver lake is about 65 miles, direct line, northwest of this town.

In the winter months the mining properties, which are scattered around the north shore of the lake, are reached by means of sleighs or dog-teams. These, starting from Le Pas, take you by way of the frozen Saskatchewan river, and over many frozen lakes and snow-covered portages, to the small town of Beaver City, situated on the south shore of Beaver lake. The distance is about 90 miles. It takes two days. As the first night out from Le Pas has to be spent in a tent with Indians, or in some other equally uncomfortable place, the rather crude boarding-house at Beaver City is in no way despised. An 18-mile run from the town takes you to the centre of mining activity on the north shore of the lake.

During the summer months a boat service is maintained between Le Pas and a point 20 miles south of Beaver City. The latter is then reached by dog-team across the 20-mile portage. A launch can be hired to carry people to any part of the Beaver lake. During the formation and break-up of the ice, the new field cannot as yet be reached.

The first claims to be staked were recorded in August 1913, in the name of the Prince Albert Exploration Company. Since this date ground has been staked for some distance back all along the north shore of the lake. In April 1914, the Beaver Lake Gold Mining Co., of Prince Albert, Saskatchewan, acquired most of the holdings of the Exploration company. Since then development has been done in a small way on several of its 32 claims. Work has been concentrated mostly on the Prince Albert claim, where, at the contact of the Huronian schist and fine-grained Laurentian diorite a 48-in. quartz outcrop can be traced for a considerable distance. This shows a good deal of coarse gold, and a little pyrite. An incline-shaft has been sunk 70 ft. on the vein. The ore thus exposed is from 4 to 5 ft. wide from top to bottom of the shaft. The average value, neglecting a few feet of enrichment on the surface, is, according to the prospectus of the Beaver Lake Gold Mining Co., $16 per ton in gold, and about 2 oz. silver. The quartz in the shaft is white, with thin seams of mineral running through it. Fine gold can be seen in most pieces with the aid of a glass. I understand that the company is arranging with Toronto people to assist in extensive development. The profitable opening of this mine may warrant the development of numerous other properties, the owners of which, in the meantime, will probably content themselves with assessment work only.

MECHANICAL REFRIGERATION, first used only for ice-making, and next applied to brewery cellars and beer wort, soon was extended to all kinds of cold-storage purposes and became the foundation of the modern fresh-food distribution system. These uses of mechanical refrigeration are today so common and well known as to obscure a more recent and valuable extension of mechanical cooling as a part of manufacturing processes. While these are constantly increasing in number and variety, there are even more instances where this type of machinery could be economically used and where, for some reason, its application has not been undertaken. Wherever the general process includes such steps as gas, liquid or solid cooling, condensation, crystallizing, fermentation, mechanical refrigeration must be carefully considered as a possible means of improving the product, increasing rate of production or permitting recovery of new products.—*C. E. Lucke.*

Eruptions of Mt. Lassen and Tertiary Eruptions of the Sierra Nevada

By H. W. TURNER

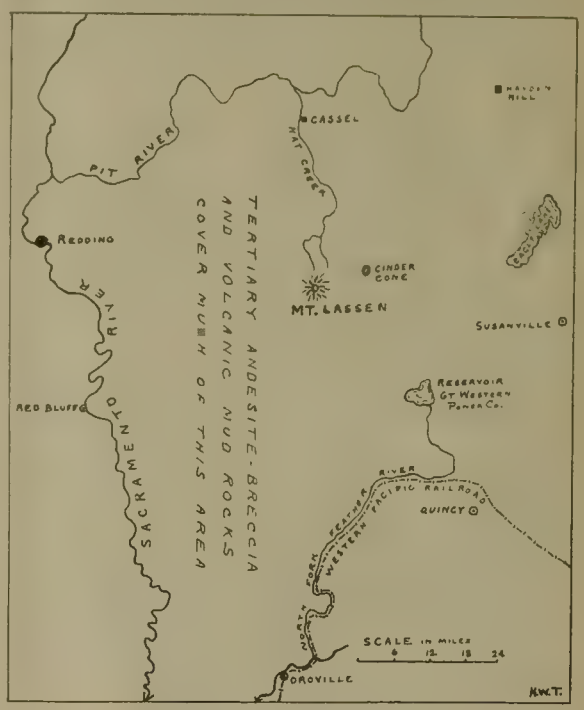
In late Tertiary time, there were many volcanoes in the Sierra Nevada, mostly in the central and northern portion. At that time, vast floods of volcanic material were emitted, covering the larger part of the area between the Yosemite Park and the Oregon border. These volcanic materials consisted both of molten and fragmental lava, the last the result of steam explosions. This fragmental material, angular pieces and fine volcanic dust, was deposited on all the slopes surrounding the volcanoes in layers more or less nearly horizontal as we find them today; but a large part of the ejectamenta, becoming mixed with water, formed enormous mud flows that filled the river-valleys and traveled westward to the present site of the Great Valley of California.

Similar mud-flows have taken place many times in Japan, even in historic time, covering farms and villages.

That broken material, if on a steep slope, can flow is well illustrated in a land-slide that took place at Frank in Alberta on April 29, 1903. A huge mass of rock, nearly half a mile square and about 400 ft. thick, suddenly broke loose from the east face of Turtle mountain and precipitated itself with terrific violence into the valley beneath, overwhelming everything in its course. The great mass, urged forward by the momentum acquired in its descent, and shattered into innumerable fragments, ploughed through the bed of the Old Man river, carrying both water and underlying sediments with it, and crossed the valley to hurl itself against, and up, the opposite terraced slopes to a height of 400 ft. Blocks of limestone and shale, mingled with mud, covered the valley to a depth of from 3 to probably 150 ft., over a square mile of area. The track of the Crow's Nest railway was hopelessly buried for nearly 7000 ft. and about 70 people were killed.

The mud-lava flows of the Sierra Nevada in their progress caught up boulders and fragments of the bedrock formation (slate, schist, and granite), and trunks of trees; the latter, becoming silicified or lignitized, have been preserved to this day. Generally these tree-trunks are found lying at all angles in the mud or 'cement' lava, but in some instances where the mud was fine-grained and the flow quiet, the trees were covered up in a standing position. Of this Ross E. Browne gives an interesting example.* The locality is the Weske channel of the Forest Hill divide in Placer county. Browne writes: "The cement filling the bed to the depth of 100 ft. is a more uniformly fine-grained material than is usually encountered. It encloses a number of trees standing on the banks of the channel, with roots intact in the gravelly soil and bedrock. One of these is nearly 100 ft. in height and 4 ft. in diameter at the base, and stands perfectly upright."

In surveying for a geological map in the Sierra Nevada, I came across two instances where the mud-lava had filled great fissures in the bedrock formations, these fissures presumably having been opened by earthquakes. One of these is at Poker Flat, in Sierra county, a place rendered famous by Bret Harte's famous story. Here



MT. LASSEN AND ITS VICINITY.

Canyon creek has cut to the depth of 1000 ft., exposing a vertical dike-like streak of volcanic ashes and fragments; and this streak continues as a narrow band up both the north and south slopes of the canyon with serpentine and slate as a wall-rock. The material near the hotel is nearly horizontally stratified, which is hard to explain on the theory of a filled fissure; in other places, it is made up of a rubble of andesite and serpentine fragments and boulders, and there are also inclusions of a white lava. In this instance no proof was obtained that this cement mixture could not have come up from below, but at a similar occurrence on Fall river, in Butte county, the fissure has granodiorite for walls and

*10th Annual Report, State Mineralogist, p. 441.

in the concrete or cement-like material of the 'dike' there are fragments of lignitized wood, as well as fragments and pebbles of pre-Cretaceous bedrock and of a basalt of a type older than the andesite eruptions. The inclusions of wood (a species of *sequoia*) and the pebbles and fragments of bedrock can only be explained by the hypothesis of an open fissure filled from above.

The larger part of the gold of California was originally deposited in veins or impregnations in the bedrock formations long before Tertiary time. The placer gold, as every miner knows, came from the vein or lode deposits by the gradual erosion of the bedrock series. Being very heavy, it was gradually concentrated in the river-gravels. Then when the river-beds and valleys were filled by the lavas and mud flows, the rivers, with a vigor renewed by an elevation of the range, cut new channels; the present river-canyons left the old channels and their rich gold gravels high and dry, though in most places they became capped by volcanic material, largely of the cement or mud-lava type. The ancient channels, known as 'deep leads,' have since produced some hundreds of millions of dollars in gold by drift and hydraulic mining.

In the Lassen Peak area there were in Tertiary time several volcanoes, which gave out both molten lava and showers of volcanic ejectamenta. The fragmental material at one time covered a large part of the area between the Pitt, Sacramento, and North Feather rivers, and the cement-lava that caps the gold-bearing gravels of the Magalia ridge north of Oroville came from the Lassen area.

Judging from all the printed descriptions, the recent eruptions of Mt. Lassen have all been of the nature of steam explosions. The hot lava fragments and dust or ashes have melted the snow and with the water from this source and from the streams they have formed mud-flows, which are reported to extend down into the Hat Creek drainage for a distance of 15 miles north of the sources of eruption near the summit of the peak.

G. M. Homans, State Forester, insists, however, that the material ejected from a new orifice on the northern slope of the peak, in May 1915, came out of the crater as a mud-flow and that the path of the flood is plainly marked down the north slope of the mountain.

According to the observations of W. H. Storms,† on June 20, 1914, the steam-explosion crater on Lassen peak was 650 ft. long, 100 or more feet in width and about 100 ft. deep. It resembled a big open-cut or 'glory-hole' and should not be confused with an ordinary crater, which is usually more or less nearly saucer-shaped and formed of rounded fragments of lava (lapilli) and volcanic ashes, which, being thrown into the air, fall down more or less symmetrically around the orifice, forming usually a conical hill with a basin in the centre. Later other cavities were formed and the larger crater altered. Prof. R. S. Holway, of the University of California, reports that: "The bowl of the old crater of 1914, formerly 300 or 400 ft. deep is now filled. The first glance, however, does not show the most interesting fact—the crater has not been filled by volcanic ash and rock fragments, but the bottom of the old crater has been literally shoved upward as a whole, undoubtedly by lava pressure from underneath." This observation by Prof. Holway seems not at all unlikely, as there must surely be a heated mass below to account for the steam explosions.

Lying about 10 miles northeasterly from Lassen peak is Cinder Cone, which has been described in detail by J. S. Diller of the U. S. Geological Survey in Bulletin No. 79. This cone of ash or volcanic sand is nearly perfect in its outlines and was undoubtedly formed in comparatively recent time, possibly less than 500 years ago. Since that eruption apparently the volcanic forces of the Lassen Peak area have been quiescent up to 1914.

The Lassen area, however, cannot claim all of the volcanic activity of California in recent time, speaking in a geological sense, for there are nearer-by, in Lake county in the Coast ranges, to the east of Clear lake, several craters from which basaltic lava issued and which are still in nearly perfect condition, indicating their comparatively recent origin. One of these, the McPike crater is symmetrical, with a saucer-shaped basin at the summit about 60 ft. deep. Lapilli cover the bottom and sides of this crater, which rises about 800 ft. above the flat land at its base. Then along the eastern slope of the southern Sierra, there are a number of craters and lava-fields showing the curious curling shapes of molten surface flows, indicating that not a great time has elapsed since the eruptions took place.

†Mining and Scientific Press, July 25, 1914.

Smelting at Greenwood, British Columbia

According to the report of the general manager of the Canadian Copper Corporation, Oscar Lachmund, the plant at Greenwood showed the following results in 1914:

The ore from the Mother Lode mine assayed from 0.396 to 0.868% copper, 0.0275 to 0.095 oz. gold, 0.149 to 0.178 oz. silver, 21.2 to 34.65% silica, 15.36 to 28.6% iron, 11.95 to 20.01% lime, and 2.37 to 13.2% sulphur.

The total amount of ore smelted from January 1 to August 23 was 299,928 tons. It consisted of B. C. Copper Co.'s ores, 193,512 tons, and custom ores, 106,416 tons. Converter slag made and smelted was 5129 tons. It contained 1627 tons of custom ore and 466 tons of clay. Coke used was 41,026 tons. It represented 13.52% of the entire charge fed to the furnaces. The time of actual operation was 450 furnace days. Charge smelted, excluding coke, was 303,430 tons. The amount of charge smelted per furnace day was 674 tons. The average grade of the matte was 39.7% copper. The blast-furnace slag contained 0.251% copper, 0.0039 oz. gold, and 0.07 oz. silver per ton. The average analysis was: silica, 41.9%; iron, 18%; and lime, 22%.

The recoveries, based on blister copper returns, slag losses, and metals tied up in process, were as follows: gold, 101.39%; silver, 75.48%; and copper, 77.27%. Production was: copper (fine), 4,116,190 lb.; gold, 14,442 oz.; and silver, 63,501 ounces.

CONCENTRATES

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Silver sulphate is an efficient solvent of pure arsenides preparatory to analysis.

Tube-mills were first used for the fine-grinding of ore in 1894 at the Moulton mill, at Butte.

Maucherite, Ni_4As_3, contains the largest proportion of nickel of all the nickel arsenides. It is widely distributed.

Tellurides at Kalgoorlie, Western Australia, are mainly confined to the richer ore-shoots, in veinlets crossing the lodes at right angles.

Fluorspar is used as a flux in basic open-hearth steel-making furnaces. It is also consumed in other metallurgic operations and in the manufacture of hydrofluoric acid.

Silver and gold recovered by concentration at the Montana-Tonopah mill in 1914 was 22.2%, out of a total extraction of 93.3%. The concentrate contained 362 oz. silver and 8 oz. gold per ton.

Filter-presses were borrowed from sugar-refining practice, and the tube-mill from the cement industry. In exchange, the vacuum-filter is now being used in sugar-mills for the treatment of crushed beets.

In regions abounding in deposits of native silver associated with arsenical minerals, the source of the silver should be attributed to the action of arsenides rather than to arseno-sulphides, such as arsenical pyrite and cobaltite.

Organic material may be removed from glass or porcelain by immersing the apparatus to be cleaned in hot sulphuric and a little nitric acid. The sulphuric-potassium bichromate cleaning mixture leaves by-products on the ware.

The capillary concentration of oil and gas in sands and fissures is an essential requirement of the organic theories, which postulate that oil was originally disseminated in shales and limestones, according to C. W. Washburne. It is not essential to the inorganic theories, under which the phenomena of concentration are capable of independent explanation, but the principles stated are thought to hold true for all oils in porous rock, regardless of their origin.

Mine mules were discussed in the Press of February 6 and 13. Recently in a coal mine at Wellsburgh, West Virginia, one mule hauled 152 two-ton cars distances of 1200 and 2500 ft. in 8 hours. In this district a day's work for one animal is from 40 to 50 cars.

Brass founder's ague, 'brass shakes,' and 'spelter chills' are names given to complaints arising from working in brass mills. There is a difference of opinion among doctors and chemists as to the cause. Zinc-oxide fume is considered by some to be part of the source of the trouble.

The change-house at the Raritan Copper Works, Perth Amboy, contains a main ventilating-pipe that is fixed along the centre of the building. Branches from it run to, and underneath, each lot of lockers. By this means it is expected that the lockers will be kept thoroughly ventilated, and in wet weather the damp clothing will be dried.

General constituents in white paints are white lead or basic carbonate of lead, zinc-white or zinc oxide, sublimed white lead, or basic-lead sulphate, and lithopone, which is a mixture of barium sulphate and zinc sulphide in molecular proportions. In addition to these major constituents there are also certain inert white pigments. These are barium sulphate, barium carbonate, calcium carbonate, calcium sulphate, china-clay, silica, and asbestine or magnesium silicate.

An instructive device at the U. S. Bureau of Mines booth at the Exposition shows, by means of flowing streams of crushed coal, the distribution of the losses that occur in burning coal in various types of boiler-furnaces. The small amount of coal that is finally made available for useful work is shown so as to impress the spectator with the need of fuel-efficiency investigations,

such as the Bureau is conducting in the attempt to find methods of minimizing the losses of fuel which now total many millions of dollars per year.

STAGE-CRUSHING at the Commonwealth mine, Arizona, using crushers, stamps, Hardinge, and tube-mills, resulted in a duty of 10.46 tons per stamp per 24 hours in 1914. The term 'stamp-duty' is hardly correct when a stamp is only part of the crushing system.

PORTLAND CEMENT CLINKER consists essentially of lime, alumina, and silica; from a mixture of these in the proper proportions a clinker possessing all the properties of a desirable portland cement can be made by proper burning. Such a clinker will consist of the three compounds, $3CaO.SiO_2$, $2CaO.SiO_2$, and $3CaO.Al_2O_3$; if, during the burning, complete equilibrium has not been reached—as happens in actual practice—there will be, in addition to the above three major constituents, two minor ones, namely, CaO and $5CaO.3Al_2O_3$.

COMMERCIAL GRAPHITE should consist chiefly of carbon in the graphitic condition, it should not melt or burn easily and should contain very little volatile or easily alterable substance. Possible adulterants of graphite which are of similar nature are gas carbon, coke, anthracite coal, lignite, bituminous coal, lampblack, and wood charcoal, all of which consist in large part of carbon. It is easy to determine qualitatively whether any of the above impurities are present although when mixed with considerable pure graphite it is difficult to distinguish between heated anthracite coal, strongly heated wood charcoal, and certain kinds of lampblack.

A PRACTICE that is fast gaining adoption in progressive power-plants is the use of paint for the inner surface of steam-boiler drums. The paint is said to afford protection against pitting. Silica-graphite paint is used for this purpose. For a number of years the manufacturers of this paint have coated the steam drums of five B. & W. boilers developing 1800 hp. As a result the drums are in almost perfect condition. In another instance—a plant equipped with similar boilers developing 8400 hp. —the interiors of the drums were scalded, painted both above and below the water-line, and allowed 48 hours to dry thoroughly. This treatment was repeated every 10 months. Not only did it stop pitting, but where it had previously occupied six men seven days to clean the drums of one boiler, two men now clean them in a day.

GASOLINE-VAPOR is not a gas, according to the suit of Locke v. Russell, decided in West Virginia on April 20, 1915. The lessees under an oil and gas lease perfected a method for condensing, saving, and marketing the gasoline that was wasting from the casing-head in the form of vapor, and tendered to the lessors the stipulated royalty based on oil extraction. The lessors claimed in addition thereto the minimum gas rentals, basing their contention on the theory that the gasoline-vapor was a gas product. The court held that gasoline-vapor was not gas within contemplation of the lease, and that the lessors were entitled to royalties based on its production as a part of the oil yield of the well.

THE ordinary forms of iron corrosion have been found to be due to auto-electrolysis, the presence of segregated impurities being responsible for differences in potential at certain areas, which set up galvanic action and cause solution and the formation of rust at the positive nodes. A similar but more rapid action takes place when an electric current is passed through an iron anode immersed in an electrolyte: salt water, for example. When damp cement contains an embedded iron anode, the cement acts as an electrolyte and the same rusting action takes place, regardless of the fact that concrete contains sufficient lime to inhibit corrosion when no electrical currents are present. With the electrolytic change of metal into oxide comes an increase in volume of the products of reaction, and there is developed an enormous expansive force or mechanical pressure, which is sufficient to crack the strongest forms of concrete.

THE CONDITION OF MATTER called temperature is a species of motion. This motion is not an organized motion of the mass as a whole, but a disorganized motion of the minute, invisible parts of the body. The temperature of a body is commonly estimated by touching it and finding if it feels hot, warm, or cold, according to E. F. Northrup in the Journal of the Franklin Institute. But if the body glows, its temperature is judged by the sense of sight, and the temperature is considered high in proportion to the brightness of the light which the body emits. Again, if a substance, ordinarily observed in its gaseous or liquid form, is seen in its solid form, and is recognized as the same substance, it is then called very cold and is said to be at a low temperature. All sense perceptions inform us that what we call temperature is a word which expresses our recognition of a 'condition' under which all matter exists, and common experience shows that this condition varies widely.

FIRE in bales of cotton at Calexico, California, was recently extinguished by kerosene. This may appear strange. The explanation is as follows: A cotton bale has been subjected to a heavy pressure. Water will penetrate it only an inch or so, whereas kerosene will go to the centre. A fire in a cotton bale does not blaze, simply smolders and eats its way into the bale. At the comparatively low temperature at which cotton burns, and where there is no flame, kerosene does not ignite. This is the explanation. After the fire is extinguished the bands are removed from the bale, and the burned portions of the cotton stripped off. It is said that the use of kerosene has practically no detrimental effect on the cotton, and after it has been spread out and aired for a few days all odor of the oil disappears. Those who experiment with kerosene as a fire-extinguisher should proceed with extreme care. Bales of cotton-waste or sacks at mines sometimes catch fire, and could be extinguished by the use of kerosene.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LORDSBURG, NEW MEXICO

NEW MEXICAN CONDITIONS.—WALDO-BEAN LEAD MINE AND MILL.—85 MINE AND DISTRICT.—EMPIRE ZINC.—PINOS ALTOS DISTRICT.—BURRO MOUNTAIN.—CHINO.

Throughout New Mexico mining properties that have been dormant for many years are being opened; active mines are increasing their production; new mills are under construction; the outlook in general is bright. New companies to be incorporated in New Mexico are: the Pittsburg Placer Mining Co., of Shandon (post-office, Derry), New Mexico; capitalization, $250,000. W. R. Dorna is agent. Brooklyn Development & Mining Co., of Albuquerque, New Mexico, has been granted a charter. W. C. Heacock is agent. The company will operate in Cochiti district; capitalization, $200,000. Gold Crown Mining Co. has been incorporated by Valacott and Fowler of Silver City, New Mexico. The Santa Fe Dredging Co. has been incorporated in Santa Fe, New Mexico, by W. T. Middleton, president, and J. A. Wood, secretary. A. Renehan is agent. Eastern office is New York Life building, Kansas City, Missouri. Denver-New Mexico Oil Co., of Dayton, New Mexico, is a recent company to be incorporated in New Mexico. M. B. Culpepper is agent.

In the Lordsburg district the Waldo-Bean lead-carbonate property has been taken over by Anderson and Brown, of Los Angeles. A 50-ton dry-concentrating mill is being built. No mining will be done at present, there being several thousand tons of good-grade ore on the dumps. Mining will be resumed after thorough tests are made in the mill. The process will incorporate the Stebbins dry-concentrator for lead-carbonate ores. The flow-sheet is as follows: gyratory jaw-crusher (Samson type), pebble-mill, trommel, fine orebins, elevator, feed-bin, and Stebbins table. Tailing will be saved for future concentration. Laboratory experiments gave a 65% lead concentrate. The ore also contains silver and copper.

The Nellie Bly mine at Leidendorf is under lease from the Susquehanna Copper Co. to Col. Randall and associates. The dump is being sorted and shipped. Mining is on a small scale. Gwartney and Fairley are mining good-grade gold ore from a small vein in adjoining claims.

The Atwood mine is being operated by the Atwood Copper Co., with J. L. Wells in charge. Regular shipments are being made to the Copper Queen smelter at Douglas. Dumps are being shipped. The hoist is being repaired. This is one of the best mines in this district. It adjoins the 85 mine.——Andrew Bain, former superintendent for the U. S. S. R. & M. Co., at the Dundee mine, is operating the Battleship claims north of the 85 mine, under lease from W. T. Scarborough and others. The mine will soon be ready for shipping.——The 85 mine, under management of A. J. Inderrieden, is shipping 400 tons of ore daily to Douglas, El Paso, and Hayden. Another 'Caterpillar' tractor from the Holt company, Stockton, California, has been added to the ore-hauling plant by the contractors, Rowan and Downey. The two tractors are handling practically the whole output of the mine. An electric-truck has been received here, but has not yet been used. Surveyors are still running lines from A. & N. M. railroad to the 85 mine, but nothing definite has been decided on relative to the construction of the spur.

The Gold Crown Mining Co. has been incorporated by E. A. Wayne and associates for the operation of mines and two mills at Twin Peaks in the Steeplerock district. The mill at Clear Lake has been overhauled. Tests are being made. The company also has a lease on the property of the Twin Peaks Mining Co., including the mill. David Gough is metallurgist. Extensive operations are said to be contemplated by the operators. ——The Carlisle and other mines at Steeplerock, via Duncan, Arizona, owned by George H. Utter, were examined this week by John H. Sully and an engineer of the Chino Copper Company.

John M. Sully, manager of the Chino company, and others have been examining property at Kinston, Hillsboro, and in the Carpenter district of Sierra county.

At Hanover, the United States Copper Co. is unwatering its shaft, preparing for resumption of work.

The Empire Zinc Co. is making progress at its Thunderbolt shaft, and is shipping large quantities of zinc carbonate ore from the Nason adit. Thunderbolt shaft is now down about 80 feet.

MAP OF NEW MEXICO.

Several shipments of copper ore have been made from Fierro, although the larger operators (Colorado Fuel & Iron Co. and Phelps, Dodge & Co.) have entirely ceased operations.

The Humboldt mine of the General Electric Co., is again under lease. This time to Nelson, Page, and Smith, who are said to have opened a good orebody. Other shippers from the district are G. W. Hightower, Minters and Atteberry, Fletcher and Bell, and Sinks.

In the Pinos Altos district the Empire Zinc Co. is constructing the concrete foundation for its mill at the Utter-Cleveland mines. Large consignments of machinery are being received. Orebins are being built at the Silver City end of the new Empire Zinc Co.'s tramway.——The Golden Giant mine has been bonded and leased to W. Hill and associates, from Dr. Hayden. The Golden Giant mill is being overhauled.——The Manhattan mine is being operated by J. Doyle and associates. Irregular shipments are made.——Peterson and Esplane are making

small mill-runs of zinc-sulphide ore, with good recovery.——Stauber and Wright will have their new mill in operation within a short time.——The Balback mine is being operated by John and Walter Oglesby.——Barnum and Rosenfeld have opened high-grade ore, according to recent reports.——McKee and Hammond are preparing to make shipments from the Cornie mine.——The whole Pinos Altos district is very active; the place is crowded with mining men.

Good progress is being made at the mill-site of the Burro Mountain Copper Co at Tyrone. The foundation for the 1000-ton mill is nearly completed. The crushing-plant and auxiliary-buildings are finished. The new town-site is being laid out, residence construction is being managed by the Hallorans. ——Shipments are being made by lessees from the Copper Gulf mines of the Savannah Copper Co.——A deal is pending for the sale of the property of the Big Burros Copper Co., in charge of King Wade.

The Silver Glance Mining & Development Co., at Treasure mountain, Camp Fleming, is operating its mines extensively and soon will be shipping ore. It has developed good-grade orebodies containing silver and copper. Camp Fleming will no doubt soon become active once more.

The Chino Copper Co. is working full force at the present time. From 140 to 150 cars of ore are being moved to Hurley from the Santa Rita mines per day. From 12 to 15 carloads of concentrate is said to be shipped daily to the El Paso smelter. The assessed valuation of the Chino Copper Co., as given by the county assessor for 1915 is $4,343,307, against $3,907,506 for 1914.

The property of the Victorio Mining & Smelting Co., at Cutter, is to be sold at Las Cruces. W. F. Jacoby was appointed trustee May 27.

TORONTO, ONTARIO

Dome Mine, Mill, and Dividends.—Imperial.—Vipond.—McIntyre.—North Dome.—Beaver.—Temiskaming Proposals.—Coniagas.—Seneca.—Superior.—Foster.—Keeley.—Copper Refinery.—Oil.

The expectation that the Dome Mines Co. would shortly pay dividends has been confirmed by a letter from the president, J. R. DeLamar, read at the annual meeting on May 25, outlining the policy of the company under the new management. He stated that on the authority of the general manager, C. D. Kaeding, he was able to announce that by the middle of the year the mill would be treating between 28,000 and 30,000 tons of ore per month with a recovery of 94%. As it was possible to forecast this result, the payment of dividends had been decided on. It was further proposed to double the capacity of the mill within the present building without loss of time and to construct a mill of greater capacity, regulated by the tonnage of ore developed by the funds now being realized from the sale of new shares.——Some alterations have been made in the Dome mill which will aid in increasing its capacity. From the last 40 stamps installed, new launders having a greater fall were put in, enabling coarse screens to be used. Two large Robinson pumps have been installed to lift the pulp to the amalgamating floor.——An abstract of the report of this company for the past year will appear in the Press next week.

Underground development has been resumed at the Imperial with encouraging results, $9 to $10 ore being extracted from the vein on the 100-ft. level.

At the McIntyre a large tonnage of good ore is being developed at 400 ft. No. 4 vein at 600-ft. is widening, with increased richness.

Good ore is being taken from a winze on the 300-ft. level of the Vipond, which is now down about 20 ft. A 6-ft. ball-mill is being installed.

The North Dome mine is now wholly owned by the Temiskaming Mining Co., the assets of the former company having been bought at the liquidation sale for $10,000.

A merger of the Beaver and Temiskaming companies of Cobalt is regarded as probable. The two companies are under the same management and have to some extent co-operated and are understood to be jointly interested in the project of sinking a deep shaft to cut the diabase sill, 1100 ft. thick. The Temiskaming has ordered a Nordberg hoist. This will be able to haul ore from a depth of 2000 ft., indicating that the shaft will be put down on its property. While the Beaver is financially stronger than the Temiskaming, the latter, since recent discoveries, is richer in ore reserves and is treating a larger tonnage, but the latter disparity will be removed by the 50% increase in the capacity of the Beaver's mill when improvements now in progress are completed.

A recent discovery at the Coniagas is regarded as important. The vein of heavy niccolite and smaltite, found on the 300-ft. level from the new shaft, is from 3 to 4 in. wide, in some places containing 2000 oz. silver per ton, in addition to wall-rock which will give a good milling ore. The shoot is in the conglomerate in previously unexhausted territory.——In the winze now down 80 ft. from the 335-ft. level, the Seneca-Superior has proved high-grade ore on the main vein. It is as strong as on the upper levels.——The Glen Lake company is opening up the old Foster property and will cross-cut the territory lying under the lake.

The Adanac company, now being organized with a capital of $2,500,000, has taken over the Coleman Development claims in the southeastern part of Cobalt.

The Keeley mine at South Lorrain and the White Reserve in the Maple Mountain district, both of which have been closed for some time, are again being worked.

The project for establishing a copper refinery in Canada, with Government assistance, to supply the extraordinary demand for copper and brass occasioned by the manufacture of ammunition on a large scale, is well under way. W. D. Matthews, president of the Consolidated Mining & Smelting Co., and C. D. Warren, of Toronto, recently had a consultation with the Government and military officials at Ottawa. The refining plant may be at Trail, British Columbia, where the works of the Consolidated are situated. It is urged on behalf of the scheme that the saving in the price of copper, which at present is enhanced by heavy freight and duty in shipping the ore to the American refineries, and the metal back to Canada, will speedily counterbalance the outlay.

Production of oil on a commercial scale has been started at Calgary by the Alberta Consolidated Co. On May 24 it gave a public demonstration of oil producing and refining at its No. 2 well. Several hundred spectators were present. In an 8-hour pumping test 75 bbl. of oil was secured, with no perceptible diminution of the supply in the well. The refining demonstration showed that about 20% pure gasoline can be refined from the crude oil, in addition to valuable by-products.

DEADWOOD, SOUTH DAKOTA

Oro Hondo, Deadwood Homestake, Echo, Anaconda, Hidden Treasure, Homestake, Columbia, Holy Terror, Wasp No. 2, Wells Fargo, Rainbow, and Monarch.—Tin.

Sinking is again under way at the Oro Hondo. In the past few weeks the auxiliary-hoist has been moved from the 1000 to the 1500-ft. level. The latter is now the basis of operations. From that level to the surface the broken rock is handled by the large double-drum hoist installed on the surface. Lateral work is being done at 1500-ft. It is probable that diamond-drills will also be started on that level at an early date. Every effort is being made by Mr. Talbert, the manager, to hasten the work of prospecting the southernly extension of the Homestake orebodies. John T. Milliken, of St. Louis and Cripple Creek, is supplying the money.

Pittsburg people, said to include Senator Oliver and William Flynn, have secured options on the Deadwood Homestake, controlled by C. E. McHugh, and the Montezuma and Whizzers

group owned by J. T. Gillmore. It is proposed thoroughly to explore the property by shaft-sinking and drifting. The ground adjoins the Homestake on the east. From a geological standpoint it is worthy of development.

More water than could be handled by bailing was encountered in the shaft of the Echo company, at Maitland, and on May 1 sinking was suspended, at a depth of 135 ft. Since that time a 10 by 12-in. single-stage air-compressor, driven by 30-hp. motor, has been installed, air from which will be utilized to operate a No. 5 Cameron sinking-pump. An additional length of cable has been spliced onto the hoisting-rope and minor repairs made. When work is resumed every effort will be made quickly to put the shaft down to the 300-ft. level.

Since removing the boilers, hoisting-engine, compressor, and other equipment from the Elk Creek slope to the Bare Butte side of the Anaconda company's property, the new shaft has been completed to a depth of 100 ft. Only one shift of miners is employed in sinking, but it is expected the crew will be augumented.

Cross-cutting is being accelerated at the Hidden Treasure shaft, at a depth of 200 ft., in an endeavor to locate the vein which dipped out of the shaft. It is now thought that faulting has occurred, and more exploratory work will be necessary than was anticipated.

IN THE BLACK HILLS OF SOUTH DAKOTA.

E. H. Clark, president of the Homestake Mining Co., is at Lead from New York to inspect the progress of operations. New construction is proceeding as fast as thorough workmanship will permit. At the boiler-plant the work of erecting the two steel stacks has been commenced. These will be 210 ft. high and 13-ft. diameter, each to serve three of the six 650-hp. boilers the plant will contain. The large amount of structural-steel work in the head-frame, tipple, and shaft-house at the B. & M. shaft is rapidly nearing completion. The great Nordberg hoisting-engine is being assembled.

McNish & Mills, of Hill City, have resumed milling of tin ore at their leased plant near that place. They had been treating 10 to 15 tons daily when wet weather interfered with ore-hauling, forcing a suspension. A good recovery is said to have been made, pan tests on the tailing showing this. The tin concentrate is to be smelted on the ground in an oil-furnace being erected. So far as known this is the only tin mill in operation in the United States at the present time.

Richard Blackstone, superintendent, and other employees of the Homestake Company, are interested in the development of the Columbia mine, at Keystone. During the winter an option on the property was secured. Prospecting is now under way. ——It is stated that Charles R. Morgan, of New York, intends doing something at the Holy Terror mine, at Keystone, which he owns. The recent inspection of the property by Louis D. Huntoon, is believed to foreshadow activity underground.

Repairs have been made to the electric hoist at the Wasp No. 2, recently destroyed by fire; everything is again running smoothly.——Lessees of the Wells Fargo ground, Holstein, Norman, and associates, are having good results. They are regular shippers to the Golden Reward mill, at Deadwood, and every few weeks send a carload of $30 to $40 ore to the Denver smelter.——Burns, Sanford, & Von Woehrmann, leasing on the Rainbow, near Maitland, are extracting milling ore which they are piling on the dump, as the property is not yet equipped with a cyanide-plant.

California miners represented here by C. D. McQueen, have secured options on the property of Sam Sweet, Thomas Charlton and others, at the head of Two Bit gulch, adjoining the Monarch. Development has been commenced.—Owners of the Monarch property, on Two Bit gulch, contemplate installing machinery. The mine has produced some rich ore, and according to all reports is not yet worked out.

James Cochran is driving a long adit to reach the orebody in his property in the Rochford district, and hopes to complete it during the present summer. This adit is intended to cut the shoot at a lower depth than any previous development. Mr. Cochran, working in a small way, with never more than two or three men employed, and milling in a small plant only the richest of the ore, has realized a fortune from this property. He now makes his home in Oklahoma, spending his summers in the Black Hills. It is interesting to note that he has been highly successful in the oil business in his adopted state.

LONDON

CROWN MINES DIVIDENDS, RESERVES, GOLD CONTENT, PAST HISTORY.—J. J. BERINGER AND TIN.

The death of Sir George Farrar happens at a time when the financial house that put East Rand Proprietary right four years ago, during a bitter disillusionment, is suffering itself from a similar adverse incident at one of its own properties, the Crown Mines, Sir George was the victim of the optimism that does not recognize the almost universal law of impoverishment in depth, for the great East Rand consolidation was not able to maintain the average grade prognosticated. Since the re-organization of working methods, the company has done well enough on the basis of 25% dividends, instead of the 40% expected. The Rand Mines group, which arranged the technical management on the new basis, is now confronted with an equally anxious problem at the Crown Mines. Put briefly, the situation may be explained by the statement that the yield per ton is a pennyweight less than the average of the ore reserve calculated on December 31, 1913. The development during 1914 also provides unpleasant evidence of impoverishment, in that the amount required by the mills, 2,500,000 tons, was not disclosed during development, 1,742,700 tons only being added to the reserve. In connection with these results, it is additionally disconcerting to find that the directors do not give the assay-value of the ore recently developed. It has been necessary moreover to re-value the ore reserve. On December 31, 1914, the figure was estimated at 10,022,000 tons averaging 6 dwt. per ton, as compared with 10,449,000 tons averaging 6.82 dwt. the year before. How much of the fall in assay-value is due to the re-valuation of old reserves, and how much to the lower grade of the ore recently developed, we have no means of judging. With the fall in the yield, it is natural that the profit cannot be maintained, the dividend now being at the rate of only 60%, instead of the 130% prognosticated at the time of the consolidation in 1909. The board of directors is maintaining discreet silence, and contents itself by announcing that investigations are being made. R. C. Warriner, the manager and consulting engineer, states that the recent developments have been so bad as to induce the idea that the variation in grade can only be temporary. It is generally recognized that alternations of the quality of the ore in this part of the Rand follow lines pitching eastward, so, taking an optimistic view, it is possible that the developments at present may be in a zone of poor ground and that later the luck may turn. Some of your readers may remember the chart exhibited by H. F. Marriott at a meeting of the Institution of Mining and Metallurgy when the non-persistence of ore in depth was discussed. His contention at the time was that, on average, the ore in the central Rand did not show a general impoverishment with depth. We can only hope that Crown Mines will take a turn for the better, but most men wag their heads ominously.

In looking through the past history of Crown Mines, some assistance is obtained in diagnosing the present position. The company is really a continuation of Crown Deep, which, with

the Crown Reef above it on the outcrop, did remarkably well for shareholders. Those two mines were to the west of the Robinson, and contained much of the same high-grade ore. Below the Robinson was the Robinson Central Deep, which also did remarkably well. Farther to the west there were many other properties, most of them deep levels below the Langlaagte Estates. These, as far as tested, all contained ore of much lower grade, 6 dwt. or less. Some had been worked with disastrous results, and one had managed to pay small dividends. But it was obvious that this great area could not be worked as individual mines, and it was decided therefore to amalgamate them with the Crown Deep and Robinson Central Deep and work the consolidated property on a big scale. The reduction of working cost consequent on a re-organization of underground work was expected to yield the margin required to make the western ground profitable. It was calculated also that the rich ore in the deep levels in the eastern section would continue. Another favorable consideration in connection with the amalgamation was that the capital required for putting the western sections on a profitable basis would be obtained from the cash resources of the Crown Deep, and no less than £700,000 was obtained in this way from the accumulated profits of the latter company. It is an open secret that funds could not have been obtained in any other way. Now that the partial collapse has come to Crown Mines, there are not a few of the original shareholders who are indulging in "ungentlemanly emphatics" in connection with the scheme of 1909. As regards the cost of re-organization, the original estimate was far too low, and another £1,000,000 had to be raised by the issue of debentures, and the expected reduction in working cost was never realized. The original estimate was about 13 shillings per ton, and the actual figure for 1914 was 15s.7d. This higher cost, now followed by the drop in grade, has had a serious effect on profits. We may take it that the rich ore of the Crown Deep and Robinson Central Deep is exhausted. A year ago an attempt was made to absorb the remains of the Robinson, no doubt with the hope that the rich ore would help the Crown Mines for a short time at least, but on the first show of opposition the proposal was withdrawn. Unless the miracle expected by Mr. Warriner and Mr. Marriott should happen, Crown Mines will take its place as a huge low-grade property like Randfontein Central and East Rand Proprietary, with dividends on a modest scale.

The late J. J. Beringer, head of the Camborne Mining School, has left behind him a posthumous paper of great importance in the domain of ore-dressing literature. Some years ago he was engaged in the microscopic study of Cornish tin ores, with the object of ascertaining the physical nature and behavior of cassiterite particles. His results were embodied in a paper presented to the Institution of Mining and Metallurgy. Long ago he told us that the finest wire screen, 200-mesh, was no good in the study of tin ore, as the particles went through "three abreast." Separation by settlement in water was necessary for the sizing of these particles, and the measurement of their dimensions had to be done by the microscope. So fine are some of the particles that their presence is only indicated by crossed nicols. To give an abstract or even an outline of his paper would be impossible, and seeing that lode-tin is not an American product of wide distribution, it would be inadvisable to make the attempt. But some of his points are of general interest. In the first place, the particles are so fine that the most convenient unit of measurement is the micromillimetre, one-thousandth of a millimetre. Second, a more detailed classification of the sizes than 'sand' and 'slime' is required, and he introduces the word 'clay' for particles of 5 micromillimetres and under, particles that would go '10-abreast' through the 200-mesh holes. The characteristic of the clay size is that on settlement they look not so much like a growing sediment but a shrinking fluid increasing in density at the bottom. As regards the behavior of particles on tables or buddles, settlement rapidly becomes difficult when the size is less than 25 micromillimetres. If the water is given a vibration on a table or Frue vanner, the settlement is greatly hindered, so that more of the fine particles are lost on a vibrating concentrator than on a stationary buddle. Another interesting point made by Mr. Beringer was that fine particles that would not settle on a table or buddle by themselves could be caught if mixed with particles of larger size. This supports the experience of many practical tin-dressers who have objected to the modern theory of close sizing. Generally speaking, he found that particles above 25 micromillimetres in diameter did not present insuperable difficulties in water-concentration. With regard to the occurrence of these fine particles, he found that their existence is not by any means solely due to pulverization during crushing, but that they often exist in the form of microscopic grains disseminated as a cloud through quartz. Mr. Beringer, throughout the paper, did not use the word 'colloid,' no doubt considering that this word is overworked by the ore-dresser.

KALGOORLIE, WESTERN AUSTRALIA

Labor Union Suit.—Gold Returns.

In June 1914, the Yuanmi Union of Workers expelled from their association six miners, who were sinking the Yuanmi main shaft on contract. This resulted in the mine being closed for 68 days. The contractors sued the union, together with the Murchison Amalgamated Workers Association, the Sandstone Workers Union, and the Industrial Association of Workers, together with 21 residents, for boycotting them, and preventing their earning a living, or even securing food or drink at any stores, etc. If it had not been for H. G. Walton, manager of the mine, supplying them with food and shelter, and conveying them in the company's auto to the Sandstone railway station, 40 miles, the men might have starved. The judgment was in favor of the six plaintiffs. They were awarded $6990 and costs. These men are now working in the Kalgoorlie district, where contracting is still in force, although a majority of the local union has, on two occasions, voted against it. This decision should be a lesson to unions, which have on several occasions in this state made themselves obnoxious.

March gold returns for the state amounted to $1,991,400. The chief producers were as follows:

Name.	Tonnage.	Value.	Profit.	Dividend.
Great Boulder	18,687	$244,400	$132,500	$328,100
Ivanhoe	20,145	162,800	50,000	.....
Kalgurli	10,870	104,200	45,000	.....
Edna May	2,887	63,200	40,000	32,100
Golden Horse-Shoe	25,267	190,500	37,900	.....
Sons of Gwalia	13,800	107,000	29,800	40,600
Sand Queen	2,000	42,000	25,500	22,500
Fenian	2,878	48,000	25,400	.....
Lake View & Star	18,800	109,400	17,900	.....
South Kalgurli	9,879	62,300	11,400	.....
Bullfinch	6,542	41,700	11,100	.....
Mararoa	2,720	24,400	8,600	.....
Menzies Consols	2,367	28,200	7,900	.....
Ingliston Consols	2,100	18,500	5,500	.....
Black Range	2,759	27,300	5,300	.....
Yuanmi	3,900	38,200	4,500	.....
Queen of the Hills	3,220	25,800	4,400	.....
Oroya Links	12,800	70,200	4,100	.....
Perseverance	21,393	103,400	3,900	.....
Edna May Central	2,100	9,400	1,900	.....
Victorious	2,822	20,200	1,700	.....
Commodore	710	6,800	1,200	.....
Corinthia North	5,540	20,700	5,700	.....
Associated Northern	193	7,400	500	.....
Kyarra	1,096	10,200	50	10,000
Great Fingall	5,030	35,400	–7,300	.....
Associated	10,812	48,500	–12,800	.....
Ida H.	1,356	23,100	–2,000	.....

Total output, $606,892,800; total dividends, $126,284,500.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press

ALASKA

Cordova

Large transactions have been taking place at New York in bonds of the Kennecott Copper Corporation. Production has been as follows: 1911, 22,854,000 lb.; 1912, 23,319,000 lb.; 1913, 17,729,000 lb.; 1914, 17,200,000 lb.; and first three months of 1915, 7,836,359 lb. The outputs in 1913 and 1914 were affected by a tramway fire and the War respectively. Net earnings during this period total $8,123,267. Most of this came from the Bonanza mine, which has been developed to 600 ft. Cost of production has averaged 4.72c. per lb. The Jumbo mine has been opened, and its mill enlarged. Metal output of the company is about 5,000,000 lb. per month. The Beatson Copper Co. is now under control by the Kennecott. Its mine is low-grade. A concentrating plant to yield 10,000,000 lb. of copper per year has been constructed.

Juneau

The Alaska Exploration Co. is being organized by Juneau mining and business men to examine and develop the resources of southeastern Alaska.

ARIZONA

Cochise County

The Mascot and Western railway, 18 miles long between the Mascot Copper mine and Wilcox, was completed on June 15. Ore is now being sent over the line to smelters at Douglas.

Operations at the Copper Queen mines and smelter are at about 90% capacity, with an increase in the near future. Churn-drills on Sacramento hill have disclosed considerable information on the west orebody. Drills are now working on the east deposit, also at the Dallas.

Work is to be resumed at the Oliver shaft of the Calumet & Arizona. This is one of the mine's producing shafts.

Gila County

(Special Correspondence.)—L. D. McClure and J. E. Miner, well known in this district, have taken a bond and lease on 11 claims of D. Baatz, J. Klinfelder, and J. W. Bennett of Globe, situated in the Sleeping Beauty range, three miles north of the International smelter. The formation is a mineralized conglomerate of large extent. Within three weeks the lessees will commence shipping 4 to 6% copper conglomerate to the Old Dominion, International, or El Paso smelters. The ore is mined by quarrying.

In the Schultz Ranch district the Copper Springs Mining Co., composed of well known Miami people, will commence active development. Prospects are very good. A heavily mineralized quartz vein occurs at the contact of granite and diorite. It has produced a good deal of copper ore. A 250-ft. adit is being driven to cut the shoot. The ore averages 6.5% copper and about 20 oz. silver per ton. A 100-ton concentrating plant is contemplated.

Miami, June 11.

Concreting of both main shafts, 584 ft. deep, at the Inspiration is nearly finished. A two-decked concrete platform is to be constructed on sub-level No. 4 for handling men. High-pressure air-pipes are to be installed underground for supplying the compressed-air locomotives. The compressors have been tested. They will supply air at 1000-lb. pressure.

The Miami mine produced 3,819,339 lb. copper from 116,845 tons of ore in May. Development totaled 1920 ft. An 800-ton ore-pocket is being cut at 570 ft. Six 10 by 46 ft. Dorr thickeners are in operation at the mill.

Mohave County

The Oatman district produced gold worth $160,000 from 14,000 tons of ore in May. This was $5000 less than in April, due to a three days' shut-down at the Tom Reed mill.——At 20 ft. depth in the Mazona company's ground ore showing gold has been opened.——The Big Jim company has started sinking to 500 ft. near two shafts of the Tom Reed.

The report of the Tom Reed Gold Mines Co. for the year ended March 31, 1915, contains the following: A winze has been sunk to 1075 ft., showing ore all the way. The main shaft is to be sunk from 850 to 1225 ft. A 150-hp. electric hoist was installed. There are 30,000 tons of ore broken in stopes. The mill treated 46,995 tons, averaging $21.33, with 96.2% extraction. The total gold yield was $1,002,407. Costs amounted to $9.21 per ton.

Pima County

Bids for construction of the railway from Gila Bend on the Southern Pacific to the New Cornelia mine of the Calumet & Arizona company at Ajo, 130 miles, were opened at Warren on June 10. It is intended to have the line finished by the end of the year.

Yavapai County

The United Verde Extension company at Jerome has bought 25 adjoining claims for $100,000, of which $10,000 has been paid. Development at 1205 ft. continues excellent. Work is also being done at 1100 and 1400 ft.——The Walker district near Prescott is showing increased activity, due to lessees and the Pine Mountain mine. The latter's 10-stamp mill is being overhauled, as is also that at the Milliken.——The Ruth zinc mine is being re-opened by W. S. Wilhelm and others. A concentrating plant will be erected.

CALIFORNIA

Amador County

After being overhauled and enlarged, the Original Amador mill resumed work on May 1. The process is as follows, according to *The Amador Record*: The new plant consists of twenty 1000-lb. stamps, two 8-ft. by 36-in. Hardinge mills, and eleven Deister tables, ten of which are double-deck. This plant, after adjustment, will have a capacity of about 300 tons per day, against 90 tons in the old mill.

The design of this mill is quite a departure from regular Mother Lode practice. Ore from the bin is fed into revolving screens having ⅜-in. openings, the oversize only going to the stamps, while the undersize, amounting to about 25%, is passed around and joins the discharge from the stamps, going to the Dorr classifiers. The sand discharge from these is fed into Hardinge mills. Excess water and slime overflow goes to the slime-thickening tank. The battery-screens vary from ¼ to ¾-in. opening, depending on the character of the ore. The object sought is to regulate the quantity of feed, percentage of water, and pebble load in the Hardinge mills so that the discharge will show a maximum of sand minus 30-mesh with a minimum of slime. Results indicate that there will be less slime than with the stamps crushing to 20-mesh.

The discharge from the Hardinge mills passes into the Hardinge amalgamator, which is attached to and revolves with the mill. Mercury is fed into the amalgamator as required by the condition of the outside plates in the same manner as it is fed into the mortar-box. Also about a dozen copper balls made

from ⅜ or ½-in. diameter wire are amalgamated and put into the amalgamator. As these roll around they form good-sized amalgam balls, which are removed while the mill is running. After the amalgam is scraped off they are returned to the machine. The discharge from the amalgamator passes over copper plates, and goes to a hydraulic classifier having three spigots for coarse, medium, and fine sand. This is fed to corresponding sand-tables. The slime-overflow from this classifier joins the slime-overflow from the classifier to the thickening tank, from which the thickened slime is run to the slime-tables, and the clear overflow from the thickening-tank is piped back and again used in the mill.

Concentrate from both sand and slime is collected in one sump and elevated to pass the second set of amalgamating plates, where any gold escaping from the first set or carried over into the slime-overflow is recovered. The concentrate from the second set of plates goes to the settling-bins, from which it is trammed to the cyanide plant. This has a capacity of 300 tons per month. The concentrate is ground to slime, amalgamated, and cyanided. T. S. O'Brien is superintendent.

The following is the preliminary statement of production and costs of the Plymouth Consolidated in May:

Ore crushed, tons	11,600
Total value	$59,841
Working expenditure	28,402
Development charge	6,196
Surplus	25,243

The affairs of the Hardenburg Mining Co., which operated four miles from Jackson, are being straightened out. The company is heavily in debt. John Martin and Henry Malloch, who own the controlling number of shares in the South Eureka Mining Co., are the principal holders of the Hardenburg company. They have made a proposal to the creditors to give one-half of their shares to the Hardenburg treasury so that the same may be sold and sufficient funds raised to pay the debts and renew operations at the mine. Creditors will not interfere for six months. Mrs. Peter Wells, owner of the Hardenburg mine, will agree to the arrangement. The property is well equipped for mining and treatment. Deeper work is hoped to reveal better ore.

Butte County

Oakland people are re-opening the Morning Star mine, near Romsey Bar. It has not been worked for 10 years.——Good reports are coming to Oroville from the Berry Creek district.

Some rich ore has been discovered in the Butte Creek district by F. E. Whitlock, according to news from Chico. A number of prospectors have started for the area.

Calaveras County

On June 7 forty stamps started crushing at the Royal Gold Mines Co.'s property at Hodson. Twenty more will be added shortly. A large tonnage of ore has been proved. The property is in good shape. Frank W. Page is manager.

Eldorado County

The Frog Pond and Collins & Bacchi quartz mines have been acquired by T. J. Daly of New York. F. C. Levitt will superintend work.

Inyo County

The Carbonate Lead Mines Co., operating 42 miles west of Zabriskie on the Tonopah & Tidewater railroad, is shipping 200 tons of ore per month. This is to be increased. According to the manager, John Salsberry, the ore averages $30 per ton.

Nevada County

(Special Correspondence.)—Favorable developments in the deepest workings of the North Star and Empire mines seem fated to bring these two companies into conflict. The lowest level, at 6300 ft. on the dip, in the North Star disclosed good ore in a vein to a part of which the Empire claims apex rights, based mainly on the Pennsylvania-W.Y.O.D. case, which ended in one of these mines absorbing the other and both being absorbed later by the Empire. That was a costly litigation, disclosing a complex vein-structure, to which the law of the apex could be applied uncertainly. In a praiseworthy effort to prevent further litigation, to be based on uncertain factors, a serious attempt was made to compromise the claims of the Empire as against those of the North Star. A final conference at San Francisco this week proved abortive and a big law-suit seems now inevitable.

Grass Valley, June 16.

Old hydraulic mining tailing at Shady creek is to be worked by a small dredge.——The vein opened at 500 ft. in the Oustamah mine continues to yield good assays.——The Cassidy, adjoining the Empire, is nearly unwatered. Electric pumps have replaced the air pumps. Sinking will soon be started.——The mill at the Ancho mine at Graniteville is being moved to the lower adit.——At the Columbia Hill claim, four miles from Washington, J. H. Sieling, W. C. Hunter, and S. E. Guernsey were killed last week in an adit. The coroner's jury returned the following verdict: "That they came to their death through the accidental explosion of powder, caused by picking into a hole that had been cut off by an explosion in the same round."

Placer County

Part of the Banner Consolidated company's stock has been acquired by English people. A large tonnage of ore is said to exist in the Eureka, Lookout, Little Banner, Hathaway, and Kirkland claims controlled near Auburn. Extensive development and erection of machinery is to be started.——Additions to the Borealis mill will soon be complete. In May 350 ft. of development was done on the 280-ft. level.

Trinity County

A 2½-mile flume is to be constructed for the Corona de Ora mine near Hawkins Bar on Cedar creek. This will cost about $25,000. The past season was a good one, but water was short, so the new scheme will augment the supply.

Tuolumne County

A description of the mines of Tuolumne county by Robert Thom has been published in the last four issues of *The Union Democrat*, Sonora. It covers the quartz, gravel, marble, and limestone properties. The large producers include the following: Eagle-Shawmut, underground work to 2450 ft. below the surface, three veins being opened, an 1100-ft. adit serves for haulage of ore, 100 stamps and concentrators, chlorination plant for concentrate, power-plants, and complete equipment in charge of G. F. Williamson. Republican—adjoins Eagle-Shawmut on south—opened to 700 ft., considerable stoping has been done, 20 stamps and concentrators, etc., managed by C. M. Delameter. Crystalline, working four wide veins to 630 ft., 10-stamp mill, controlled by C. E. Shafer. Harvard, opened to

MAP OF TUOLUMNE COUNTY.

1750 ft., lode up to 30 ft. wide, complete mine plant, 60 stamps and concentrators, 1000 hp. electric plant, managed by H. W. Gould. Dutch Sweeney, developed to 1867 ft., ore-shoot between 600 and 800 ft. levels was 250 ft. long and 60 ft. wide, 40-stamp mill with vanners, crushing 200 tons per day, costs $2.25 per ton. Black Oak, near Soulsbyville, a well-known producer, vein in granite, ore somewhat complex, three incline shafts, 17 levels, considerable faulting, 20 stamps and all-slimming cyanide plant, complete surface equipment, all controlled by Rodger C. Knox. Draper, near the Black Oak, opened to 560 ft., 10 stamps, etc., in charge of C. Sullivan. Other mines, some producing, developing, and idle, some with large outputs in the past, are the Clio, Hart & Jacobs and Ham & Birney, Alabama, Manganite and Carlin, App, Santa Ysabel, Jumper, Mazeppa, Tarantula, Densmore, Horse Shoe Bend, Confidence, Lamphere, Excelsior, Dreisam, Soulsby, United, Providence, Spring Gulch, Buchanan, Longfellow, Sugarman, Hope, Bonanza, Sam Guiseppe, and Golden Gate. Gravel mining is confined almost to the deposits in the Table Mountain channel, and the deposits in the east belt area. The Springfield Tunnel & Development Co., A. L. Horner, manager, and J. Cademartori, superintendent, has six channels converging in its property west of Springfield. Past development proved valuable gravel, but water was too strong for the shaft pumps. Shafts were abandoned in December 1913, and an 8 by 8-ft. adit started below bedrock. Drainage would be accomplished by the adit. The total length is to be 12,000 ft. It is in 2500 ft. Gravel extraction will commence in July, from which rich returns are expected. A 240-ton Krogh gravel-mill is part of the equipment. The Saratoga claim adjoining the Springfield is still being worked.——A number of other gravel mines are in the vicinity, having a large aggregate past output.——The Rough & Ready and Stanislaus owners are busy.——Marble is being extensively quarried by the Columbia Marble Co., three miles northwest of Columbia.

COLORADO

Lake County (Leadville)

Underground work at the Big Four mine is to be resumed, the rebuilt surface plant being complete.——In the Ponsardin, on Yankee hill, the new orebody at 430 ft. depth is 70 ft. long and 15 ft. high. It assays 23 to 31% zinc, 19% lead, and 6 oz. silver per ton. The Penrose shaft pumps had lowered the water so that lessees were able to start in a level that had been flooded for years. Pumps have lowered the water in the Penrose shaft 140 ft. They are working at 350 ft.——The Twin Lakes and Lackawanna districts are busy.

Teller County (Cripple Creek)

Stratton's Independence, Ltd., advises that in April the mine output was 5489 tons of $6.50 ore. The mill treated 8387 tons of mine and dump ore. The net profit was $8000.

IDAHO

Shoshone County (Coeur d'Alene)

The water-flume to the Frisco mill at Gem is nearly finished. It is 6000 ft. long and 24 by 36-in. cross-section and will supply 600 hp. The mine will employ 200 men when water and power are available.——The vein in the Snowshoe at Mullan has widened to 12 ft. It is in 1600 ft. from the mouth of the adit and 1000 ft. vertical depth.——A deadlock still exists between the Hercules company and the A. S. & R. Co. over the smelting contract.——The Marsh mine and mill are in operation. They have been closed since May 31, 1914, being closed on account of the low price of lead.——Development at the Red Monarch is encouraging. This mine is in Missoula gulch near the Interstate-Callahan. An adit is being driven to cut two veins. A third orebody contains silver and zinc. A Fairbanks-Morse compressor is being installed.

During May the Stewart company sold about 3,000,000 lb. of lead. Profits were over $80,000.

MICHIGAN

Houghton County (The Copper Country)

Copper production of the mines of this district in May was as follows:

Mine.	Pounds.	Mine.	Pounds.
Tamarack	402,300	Hancock	90,000
Osceola	1,785,000	Isle Royale	755,700
Ahmeek	1,871,000	Arcadian	6,800
Wolverine	725,000	Winona	140,000
Mohawk	1,236,000	Victoria	225,000
Franklin	47,700	Calumet & Hecla	8,500,000
Centennial	235,000	Copper Range	5,100,000
Allouez	805,500	Quincy	2,100,000
Mass	568,000	White Pine	250,000
Superior	330,000		

This output was worth about $5,100,000.

The White Pine Copper Co. has issued a report for 1914. Development at three shafts amounted to 5617 ft. Openings on the 1st level west of No. 2 shaft have been rather poor. The 2nd level east of No. 4 shaft has been badly faulted, but shows good copper ore when in the lode. The 2nd and 3rd levels west of No. 3 shaft have opened fair ground. These two levels between No. 3 and 4 shafts are very good. The 4th level drifts, east of No. 3 and east of No. 4 shafts, are good as far as opened. There was hoisted 8000 tons of copper ore, making about 28,000 tons now in stock-piles, all from openings. Operation cost $122,395, and construction $195,929. Balance of liabilities at the end of 1914 was $134,559.

Part of the shaft-house at the C. & H. No. 4 shaft was burned last week. This is being re-built. The re-grinding plants are busy on mill and lake tailing.——The Ahmeek has five stamps dropping at Hubbell. Another will be ready in a few weeks.——At 900 ft. in the New Arcadian, 385 ft. east of the amygdaloid formation, mineralized conglomerate high in copper has been opened. This ore has never been found in this area before.——The Hancock company has raised wages 10%, starting May 29. This brings the rate equal to that in force before work was stopped in August 1914.

MISSOURI

Jasper County

Up till recently tailing plants in the Joplin district were idle, or working with small profit. The increased price of zinc has made all plants active and profitable.

A 300-ton mill is to be built by the G. & L. company in the Lawton district, costing about $20,000. Drilling showed a 40-ft. face of ore averaging about 6% zinc.

MONTANA

Broadwater County

Prospecting and development in the Radersburg-Hassel district is reported to be increasing. The Keating company has cut a station at 1200 ft. Bad roads have interfered with hauling ore.——The Black Friday company is working at 400 ft., and the Greenhorn at 260 ft. Copper-silver ore occurs in the latter.

Cascade County

The Great Falls concentrating plant is to resume work. From 1500 to 1800 tons of ore from Anaconda will be treated daily.

Granite County

The Brooklyn mine at Princeton has been acquired by Minneapolis and other people. G. G. Thomas and C. E. Jury, of Toronto, Ontario, are examining the property. A lower adit is to be driven. A concentrating plant for the zinc ore is to be erected at once. C. W. Beckley, of Butte, completed the deal.

Lewis and Clark County

(Special Correspondence.)—Over 100 men are employed in

the Marysvale district. Three Lane mills at the Gloster have been started. Marysvale and Bald Butte ores are free milling as a rule, although there are some complex ores near the latter place. These have not been thoroughly prospected. Likewise the Lost Horse area.

Marysvale, June 10.

The Shannon mine in the Marysvale district has been acquired under bond and lease by the Barnes-King Development Co. About 2000 ft. of work has been done in the property. A wide lode of $17 ore has been opened. It is intended to construct a tramway from the mine to the company's mill at the Piegan-Gloster, 2½ miles distant.

Missoula County

(Special Correspondence.)—The Curlew mill is being remodeled. It will treat a dump of old tailing at the rate of 200 tons per day. Water concentration and pneumatic flotation will be used to recover the gold, silver, and lead.

Victor, June 10.

Silverbow County

Nearly 100 men are working at the Butte-Alex Scott mine. The daily output is about 2½ carloads of ore from 2000 ft. In April the net return was $19,916. Sinking is under way to 2200 feet.

In Bulletin 102 of the A. I. M. E., C. L. Berrien, of Butte, discusses fire-fighting methods at the Mountain View mine. The paper is accompanied by 11 plans of the mine. He states that many fires have occurred in the mines of Butte in recent

500-FT. LEVEL OF MOUNTAIN VIEW MINE, BUTTE.

years. While all have been of a serious nature, simply because they were mine fires, six of them have been especially dangerous in respect to loss of life and property, and the expense of extinguishing or controlling them. It is needless to say that everything possible has been done to check all fires at the beginning, but without success in some cases; and it has then become necessary to bulkhead all connections to them, in which state several now exist. Mine fires occur in both accessible and inaccessible workings. That in the Mountain View was in the latter class of fires. It started in June 1913, between the 500 and 600-ft. levels, and at the end of that year was apparently extinguished. It was suspected that there was fire before that date. There is no space on this page for details of the work done to put out the fire. For five months 670 gal. of water per minute was poured onto the area. When the water reached the pumps it contained about 1% copper. No time was lost underground, the mine producing 1600 tons per day during the fire period.

NEVADA

Esmeralda County

(Special Correspondence.)—Five new working faces of the Jumbo Extension mine are in ore of high grade and a sixth, the raise from the south drift on the 107-ft. level, has penetrated the shale-latite contact area of silicified-latite and should reach the hanging wall, where the best ore is found, within a few days. If the ore proves to be present here, in quantity and grade approaching that on the upper levels, the development must be regarded as of great importance, owing to the distance, over 350 ft., on the dip of the contact below or beyond the rich 524 drift. It will further establish the trend of the orebody toward the adjoining St. Ives claim of the Merger Mines Co. The mine is now shipping 100 tons daily, the average value being approximately $50 per ton. Regular production will be 75 tons until the Velvet shaft is completed, when the output can readily be doubled. All litigation in any way involving the Jumbo Extension company has been settled satisfactorily.

Daily shipments are made from the Atlanta mine. Ore is broken for a width of 15 ft. in the main stope, opened from incline raise 1007-A, 115 ft. on the incline above the 1750-ft. level. In the 1010-A air-raise, 80 ft. below the 1400-ft. level, ore was exposed that assayed 3 oz. gold, in addition to copper and silver. Three other raises are being driven in ore.

Goldfield, June 14.

In the Jumbo Extension the ore-shoot has been proved to a depth of 910 ft. J. K. Turner states that they are now raising on four feet of $60 ore from the 957-ft. level and winzing from the 880-ft. level on three feet of $120 ore. These will connect and expose over 150 ft. on the dip. They raised to the ore from the 964-ft. level, and then began sinking a winze on the ore. At a depth of 910 ft. vertical from the surface, or six feet down in the winze, four feet of bornite has been exposed sampling $175. On June 8 three feet of the winze assayed $172.60, and on the day previous the first shot opened two feet assaying $125.34. Raise 524A is up 42 ft. in ore, from which a sample from 67 cars gave $60.64. A face sample from the same raise yielding $73.36. They are extracting a little sweetening from the old workings that give some better idea of the resources of the Jumbo Extension. Seventeen cars from the 511 stope sampled $151.12 and 52 cars from the same place sampled $178.42. A surface grab of 114 mine cars on the same day gave $90.88 per ton. Development at 500 ft. in the Booth is sometimes revealing shoots of $45 to $70 ore.

Humboldt County

The erection of a custom mill at Willard is contemplated. Sixty tons of over $60 ore has been sent to the mill at Rochester from the Cole-Huntington lease on the Weaver property. ——The Stowell Mining & Leasing Co.'s adit at the Limerick is in 457 ft.——The Buck & Charley Leasing Co. is shipping 100 tons per month.——Eighteen inches of $60 ore is being opened in the Colligan lease on the Weaver.——The Codd lease is shipping 50 tons daily to the mill.

Lincoln County

The Prince Consolidation company will distribute 2½c. per share, or $25,000, on July 1. The daily output is about 300 tons of lead-silver-iron-manganese ore from the 200, 300, 400 and 500-ft. levels. A winze has been sunk 100 ft. below the 600-ft. level.

Mineral County

It is reported that a wide body of $25 ore has been cut in the Aurora Consolidated.

J. H. Monjar will erect a 10-stamp mill on his Baron mine near Rawhide.

Nye County

Six mines and lessees (104 tons) at Tonopah last week produced 10,392 tons of ore valued at $213,016.

On June 9 directors and shareholders of the Tonopah Extension, Tonopah Merger, and Tonopah Victor Mining Companies agreed on a consolidation of the properties. The management will be under that of the Extension. The Extension mine has been developed to 1350-ft. depth, a large ore reserve exists, and a good mill is in operation. The output last week was 1790 tons. In the Golden Anchor claim of the Merger are two veins. The north vein is 250 ft. long at the 1170-ft. level. The south vein has been opened on three levels, that at the 1170 ft. being the full length of the claim. The output last week was 351 tons. No ore has been opened in the Victor, but the Merger veins will probably continue into the Victor. Recent

work at 1260 ft. in the Extension shows the shoot so far to be 225 ft. long, up to 20 ft. wide, of good value. Results at 1350 ft. are also excellent.

OREGON

Josephine County

(Special Correspondence.)—Development of the upper portion of the Granite Hill mine on Louse creek is being continued by the Oregon Gold Mines Co. The lower workings are flooded. The stamp-mill is being overhauled. A 12-ft. lode was recently opened, and it is hoped to keep 10 stamps at work. Melting of the snow in the upper Siskiyou has resulted in numbers of prospectors starting work. Some are in the remote areas along the Oregon-California line. Hydraulic mines have been cleaning up. Some closed earlier than usual, due to a light snowfall. More interest is being taken in copper deposits of the county than usual. Construction of the new line from Wilderville will make them more accessible.

Grants Pass, May 27.

UTAH

Beaver County

At 325 ft. in the Paloma mine, in the Star district, 18 in. of high-grade lead-silver ore has been cut in limestone. The new hoist is working well. A small compressor is to be bought.

Juab County

A recent report on the Tintic Standard states that the main 1000-ft. level has been extended 221 ft., 546 ft. beyond the main ore winze. Several short cross-cuts passed through ore. Prospects are encouraging. A good deal of work is under way at 1200 ft. The Tintic district mines shipped 124 cars of ore last week.

To enable an increased output of lead-silver ore, the Eagle & Blue Bell company has ordered an electric hoist capable of hauling from a depth of 2500 ft. The whole surface plant is to be motor driven. Development at and below 1700 ft. is highly satisfactory.

More men are to be employed at the Chief Consolidated. The present force is over 100.——The Gemini company and lessees are benefiting considerably from the increased price of lead.——Several dumps in the district are being actively worked.

Salt Lake County

After being closed for several months, the result of its financial condition, the Ohio Copper Co.'s property at Bingham has been leased to the General Exploration Co. Work is to be resumed at the mine and mill at once. A large tonnage is to be treated.

In the Big Cottonwood district, the winze in the Cardiff is down 60 ft. in lead ore. The orebody is of considerable size. Some copper ore is also showing in the bottom. The new road is almost complete. Shipments are then to be increased to 100 tons per day.——The Price Mining Co. is to install an electrically-driven compressor, and machine-drills. Most of the property is on Montreal hill.——The interest of John F. Cowan in the Columbus Extension has been sold to Salt Lake City people. The total deal involved about 123,000 shares.——Tests have been made at the Wasatch Utah mine with the Koehring cyanide process. Results are reported to be good.

Zinc carbonate ore, assaying 39.6% zinc, has been opened near the surface 100 ft. above the main adit of the Relief claim of the Wasatch company. It promises to be an extensive lode. Shipments are soon to be made.——At the Emma copper mine the shale-limestone contact has been reached. Driving southeast is under way to reach the intersection of the contact with the Brain fissure.

Summit County

The Snake Creek tunnel was in 11,192 ft. last week. In May the advance was 330 ft. The formation is diorite, hard to drill, but breaks well. The flow of water is over 8000 gal. per minute.

PERSONAL

Howland Bancroft is at the Palace Hotel.

E. Gordon-Davidson is here from Lima, Peru.

George H. Garbey was at Pittsburg this week.

J. H. Mackenzie is on his way to Juneau, Alaska.

William Hague has been in San Francisco this week.

A. G. M. Bevan has returned to London from Siberia.

H. G. Cannon, of Los Angeles, was recently at Prescott, Arizona.

F. E. Browne has taken an office in the Hellman Bdg., Los Angeles.

H. W. Dubois, of Philadelphia, has gone to the Copper River district, Alaska.

J. B. Tyrrell has gone to the Michipicoten district in Northern Ontario.

Michael Th. Ortin is visiting the mines of California on his way home to Russia.

H. E. West, of Chas. Butters & Co., sailed on June 16 by the *Kroonland* for Peru.

I. D. D. Daimpré is now with the Canadian Copper Co. at Copper Cliff, Ontario.

C. J. Klinker is superintendent of the Eaglebird mine, at Washington, Nevada county.

F. W. Bradley sailed by the *Mongolia* on June 12 for a holiday in the Hawaiian islands.

A. M. Yonge has returned to Costa Rica, to resume the superintendency of the Mina La Union.

George Watkin Evans, of Seattle, has recently returned from a professional visit to New York.

W. E. Hopper, professor of mining geology in the Michigan College of Mines, is expected here shortly.

A. MacDonald has been engaged as mill superintendent by the Hammond Mining Co., at Glacier, Washington.

G. B. Massey recently resigned from the Bucyrus Co. He has opened a consulting engineer's office in Chicago.

Frederick G. Clapp has recently returned from a year and a half spent in geological explorations in China. His address is, as before, 331 Fourth Ave., Pittsburg.

Robert M. Keeney has resigned as mill superintendent of the Baker Mines Co., Cornucopia, Oregon, to become manager for the Magnesium Manufacturing Corporation, at Rumford, Maine.

Obituary

J. J. Beringer died at Camborne on March 29. He was known all over the world for his text-book on assaying; he was recognized by Cornishmen as an authority on all that concerned the technology of tin; he will be remembered by his students as an original, witty, kindly, and most helpful teacher; he will be mourned by his friends as a courageous soul and a loveable character.

Schools and Societies

The Utah branch of the A. I. M. E. will hold a meeting at Eureka on July 15. A large attendance is expected.

The International Engineering Congress, which meets in San Francisco on September 20 to 25 has issued a booklet describing the general program, including accommodation and excursions.

The Massachusetts Institute of Technology *Bulletin* 3, Vol. 50, covers the summer courses of 1915. These will be held from June to September, inclusive, supplementing the work of the regular school year. They are open to persons who are not students of the school.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, June 17.

Antimony	35 —35¾
Electrolytic copper	20½—20¾
Pig lead	6.50— 7.45
Quicksilver (flask)	$90.00
Spelter	25 —25¼
Tin	39½—41
Zinc-dust, 100-kg. zinc-lined cases	No quotation

The zinc-dust market is uncertain. The Australian embargo has complicated the situation.

EASTERN METAL MARKET
(By wire from New York.)

NEW YORK, June 17.—Copper is quiet; lead is very uncertain, there are plenty of sellers, and there is every prospect of a decline; zinc is dull, the decline being on account of re-sale offering.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date		Average week ending	
June 10	49.25	May 5	50.33
" 11	49.37	" 12	50.06
" 12	49.37	" 19	49.93

June	56.43	....	Dec.	49.27	....

The silver market is weak. London advice describes it as quiet and dull. Buyers have not shown much inclination to come forward. Enquiry from the Indian Bazaars has been small. It would appear as if 'bull' operators had laid up as much as they are disposed to hold at present. Their holdings have not been built up from purchases in the London market alone; fairly substantial supplies have been drawn from China and elsewhere. America has placed a fair amount on the market daily at current rates, but there is no pressure to sell from that quarter. Exports of silver from London to the East for the first five months of 1915 are about 12,000,000 oz. less than in 1914. Cobalt shipments last week were 382,464 oz. On June 12 410,000 oz. left San Francisco for the Orient.

COPPER

Prices of electrolytic in New York, in cents per pound.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

On June 16 tin was 41 to 42c. per pound.

ANTIMONY

Aside from a good business on one or two days in which a few hundred tons of Chinese and Japanese changed hands, there is nothing to report. The quotations range from 36.50 to 38c. The consumption of antimony in the making of shrapnel bullets will increase. The buying of the past week has been on the part of shrapnel makers.

ALUMINUM

The market for metal, 98 to 99% pure, is now quoted at 28 to 30c. While the demand has been slowly increasing, the advances in price are based largely in sympathy with the other metals.

Eastern Metal Market

New York, June 11.

Nearly all of the metals have gained in strength and quotations have gone higher. A cessation of the rush to buy spelter brought about an easier market in that commodity. Electrolytic copper has exceeded 20c. The indications are that it will go higher. Only a slight renewed demand for zinc would serve to send its price upward again. In lead there has been great pressure to buy. The American Smelting & Refining Co., has continued to advance its quotations from day to day. On June 11 its quotation was 6.50c. Independent sellers have been forced to decline attractive business because they did not have lead to sell. Tin has been active; aluminum has advanced, and in antimony a good business has been done at the high prices quoted.

The manufacture of munitions of war is assuming larger proportions every day. More and more of the larger industrial concerns are engaging in the work, and still others would take it up if the necessary machinery could be obtained in reasonable time. Some of the machine-tool manufacturers have sold all of their product to next January, and practically all are sold up to October or November. Many companies having war contracts have not yet organized the work, or have not completed plants for the new line of business, and a good part of their demand for the metals lies in the future. General business in the metal trades continues to improve, as evidenced by the call for equipment. The production of pig iron in May was 2,263,470 tons, against 2,116,494 tons in April, an increase of about 3000 tons per day. About two-thirds of the increase was contributed by steel-works furnaces.

Estimates put the aggregate of war orders placed in this country at about $500,000,000. The Bethlehem Steel Co. is credited with having over $100,000,000 worth. These figures are not excessive in the judgment of those in touch with the situation, and resultant business is spreading in new directions.

COPPER

Renewed demand from the manufacturers of munitions of war was particularly active in the first half of the current week. There are still good inquiries pending from the same sources, and from export buyers as well. Under this stimulus prices have advanced. The buying did not last long in full force, but the market was left firm at higher levels. At the close of June 9 producing interests were asking 20c. for electrolytic and the following day they asked 20.12½ to 20.25c., full terms, for July, August, and September shipments, but copper can be had today at 20c. Higher prices are predicted when the enormous war orders get in full swing. Lake is higher at 20 to 24c., choice brands commanding the higher figure, if it is found. The foreign market is firm. It is interesting to note that manufacturers of copper products are building up a good trade with countries supplied by Germany prior to the War. Chile, for instance, is taking rolled products, and some have been shipped to Scandinavian countries as well. The trade believes that a good part of this business will prove permanent, especially that with South America. Since the withdrawal of price lists on brass and copper products, only the outside market can be quoted and prices are almost entirely a matter of private negotiation. The base price of sheet copper today is about 25c. The International Nickel Co. has advanced its prices of monel metal, a natural nickel and copper alloy. It now quotes round rods at 28c., and flats at 29c. per lb. Exports of copper are proceeding at a fair rate, and up to June 12 totaled 8392 tons. The imports at New York, Baltimore and Philadelphia in April totaled 8700 tons, against 12,000 tons in the same month last year. In the first four months of this year the total of imports at those ports was 33,700 tons.

SPELTER

The scramble to get zinc at almost any price has subsided. Business is lacking and quotations have eased off. On June 10 offers were made around 25c., compared with 26.50c. for prompt deliveries in the preceeding two or three days, and June 11, there were offers at 24c. for June and July. Choice brands of brass-mill spelter are nominally quoted at 30 to 35c. Jobbers in galvanized sheets are offering to their customers sheets coated with lead and a small proportion of tin, since the price of galvanized sheets went up. Some of the mills making that product are now quoting No. 28 gauge at 5c., Pittsburg base, and others have ceased galvanizing altogether. Painted black sheets are freely substituted, and this is most natural in view of the fact that some engineers always have advocated the use of painted sheets. Many stories are going the rounds about spelter. One which does not deserve credence is that pro-German interests have control of its sale and are determined to make the Allies pay dearly for it; and it is also asserted that the supply is not so meagre as the selling interests assert. It is predicted that a large offering would bring prices down with a rush. Old and experienced students of the market assert their conviction that manipulation has little to do with the situation, and point to the fact that America is supplying almost the entire world. A lessened demand is about all that can bring prices down. Influences in this direction are the present substitutions for galvanized sheets, and the use of sheet copper in place of sheet zinc. The exports up to June 12 amounted to 8723 tons. In England much the same situation exists as prevails here, some of the consumers having shut down their works and disposed of their stocks and purchases of the metal.

LEAD

There has been a wild rush to buy and quotations have advanced in a most sensational manner. The buying of course, was responsible for the sky-rocket trend of prices. The largest interest quoted as follows: June 3, 5c.; 4th, 5.20; 5th, 5.20; 7th, 5.50; 8th, 5.75; 9th, 6; 10th, 6.25; and 11th, 6.50c. For a time after the metal reached 5c., the quotations of independents at St. Louis ranged higher than those at New York. At all times the outside quotations were higher than those of the largest interest. On June 10, for instance, the outside quotations for prompt delivery were 6.50 to 6.75c. and June 11, 7 to 7.25c. The general explanation is that the independents loaded up for contracts at low prices, leaving the so-called Trust practically in possession of the field. The exports up to June 12 amounted to 3273 tons in the month.

TIN

In the week June 3 to 9 a heavy business was done. The largest day was June 3, when probably 750 tons changed hands. Most of the buying was on the part of consumers who took all positions, but favored futures. Even September deliveries from the Far East found a ready market. Guaranteed deliveries brought premiums. At the close June 7, after a day of activity, June deliveries commanded 39c., and July 38.25c. The following day spot brought 40c., and today the quotation is 40.75c. Small stocks and very little to arrive in the next two weeks point to a tighter market for spot metal. The arrivals up to today, June 12, total 1225 tons. There is afloat 5685 tons. It is stated on good authority, that by the end of this year the A. S. & R. Co., will have a plant in operation at Perth Amboy, New Jersey, for the smelting of Bolivian tin ores.

In April, 1,387,636 lb. of tin was imported at San Francisco and 1,522,185 lb. at Washington ports, according to a report of the Department of Commerce.

COMPANY REPORTS

CALUMET & HECLA MINING COMPANY.

The report of this company, which has paid $124,250,000 in dividends to the end of 1914, has just been issued for last year. Like all other copper mines, operations were curtailed for some time late in the year. There was $1,000,000 distributed in two dividends of $5 each per share. Results are best shown in tabulated form:

	1914.	1913.	1912.
Development, feet	11,468	13,534	29,689
Mining cost per ton	$1.85	$2.38	$1.91
Ore treated, tons	2,592,462	2,035,625	2,806,610
Tailing treated, tons	351,929	388,164	481,320
Total copper yield, pounds	53,691,562	45,016,890	67,856,429
All costs per pound, cents	11.35	14.25	9.86
Dividends from subsidiaries	$915,439	.....	.....
Surplus	$6,902,866	$6,553,964	$10,716,414

The company holds large interests in 13 important companies in the copper country.

ROUND MOUNTAIN MINING COMPANY

This company operates a lode mine and placer deposit at Round Mountain, Nye county, Nevada. The illustrated report for the two years, April 1, 1913, to March 31, 1915, covers 34 pages. The general superintendent, R. H. Ernest, reported as follows:

The property now has an area of about 800 acres.

	1913-1914.	1914-1915.
Development, feet	4,211	4,707
Cost per foot	$7.27	$8.40
Material hoisted, tons	133,570	.....
Waste sorted out, tons	76,383	.....
Ore treated, tons	57,187	48,230
Average value per ton	$5.28	$6.57
Extraction, per cent	86.1	86.8
Total cost per ton	$4.59	$5.06
Litigation per ton	0.04	0.06
Revenue	$278,584	$292,295
Net operating profit	13,358	44,931
Cash	52,702	47,950
Surplus over liabilities	265,854	296,646

The output to date is 331,445 tons worth $2,594,819. Of this there was a profit of $730,900. Dividends paid, none last year, total $363,965.

No estimate has been made of the ore reserves, but the property is in better condition than at the end of the previous year. A large tonnage of ore has been developed between 800 and 900 ft. Cross-cuts 461, 501, and 702 have blocked out a good deal of low-grade ore. These results show that operation may be conducted on a larger scale.

Reference has been made in the PRESS several times to the 8-mile pipe-line being constructed for this company. It will bring water to the gravel deposit, which is of considerable interest. The Mountain Power & Water Co. worked this under lease until March 31, 1915. Their work, sampling and surveying indicated a large area of profitable ground. From 1906 to 1915 lessees handled 218,818 cu. yd., yielding $1.55 per yard. Their profit was about 50% of the gold recovered. Reserves of gravel are 1,508,445 cu. yd., averaging $1 per yard. Other areas will add to this. Water-rights were secured on Jett creek. A contract for pipe was awarded the Western Pipe & Steel Co. of San Francisco. This firm made riveted pipe, and the Youngstown Sheet & Tube Co., Ohio, made lap-welded pipe. Sluicing should start on June 15. The whole scheme cost $145,000.

MINING DECISIONS

MINING CONTRACT—DEFECTIVE TITLE

Purchasers of mining property, the title to a part of which failed or proved defective, who took possession of the property, could not, while retaining possession, resist payment of the purchase price.

Carter *v.* Butler (Missouri), 174 Southwestern, 399. February 9, 1915.

MINER'S LIEN STATUTE NOT RETROACTIVE

The new Arizona law (Laws 1912, c. 66) giving the employees of a purchaser of mining property under option contract, a lien for labor on such property, is not retroactive, and cannot apply to an owner who gave an option prior to the amendment. The optionee under such a contract is not the 'agent' of the owner, and cannot authorize a lien for his employees where the law did not so provide at the time he made the contract.

Oceanic Gold Mining Co. *v.* Steinfeld (Arizona), 147 Pacific, 717. April 17, 1915.

RIGHT TO DEPOSIT WASTE IMPLIED FROM EASEMENT GRANT

A deed granting the right to drive a tunnel through the grantor's property, and to use said tunnel for the operation of the grantee's mines, was held to convey by implication, the right also to dump on the grantor's property the débris and waste from such mines. The extent to which such surface can be used for these purposes was held to be a question of fact for the jury.

Himrod *v.* Ft. Pitt Mining & Milling Co. (Colorado), 220 Federal, 80. January 6, 1915.

SALE OF MINING LEASE—FORFEITURE OF CONTRACT

Claimant, a lessee of iron-ore lands which it was mining under a 30-year lease, transferred all of its property, including its plant, machinery, ore on hand, and leasehold interest to another who subsequently became bankrupt, in consideration of a cash payment, and a further payment of large royalty for fifteen years, with a specified minimum payment each year, payable quarterly. After about seven years there was a default in a quarterly payment, and the claimant at once gave notice of forfeiture and took possession of the property. It was held that the contract in question was an executory contract of sale of a leasehold interest, and that claimant having terminated the contract for default in payment of an installment of the purchase price, it could not also recover such.

G. W. Youngs Machinery Co. *v.* Courtney (Michigan), 219 Federal, 868. January 5, 1915.

CONVERSION OF ORE—PRIORITY OF LIENS

On September 14, 1911, the Clinton Mining & Mineral Co. recovered a judgment against the Imperial Mining & Milling Co. for $14,105.20 for unlawful conversion of ore belonging to the plaintiff. On April 26, 1911, the Imperial company executed a mortgage deed of trust on all of its properties to the Trust Company of North America. The judgment creditor brought suit to have the judgment declared a prior lien to the mortgage, on the theory that the proceeds from the sale of the unlawfully converted ores had been invested in the properties in such a manner as to augment their value. But on showing that the proceeds of the ores had all been spent in operation, and that the fund could not be traced to any permanent investment, there was held to be no need for intervention of equity.

Clinton Mining & Mineral Co. *v.* Trust Co. of North America (South Dakota), 151 Northwestern, 998. April 6, 1915.

BOOK REVIEWS

VALVES AND VALVE-GEARS. By Franklin DeRonde Furman. Vol. I, Steam Engines and Steam Turbines. P. 246. Ill., index. John Wiley & Sons, Inc., New York. For sale by *Mining and Scientific Press*, San Francisco. Price, $2.50.

The present volume is to be followed by another on valve-gears for gasoline, gas, and oil-engines. Together, they will form a complete text-book on the subject. Starting with the fundamental principles governing the admission of steam to the cylinder, the use of both the Zeuner and Bilgram diagrams is explained. Practical problems are given in the design of the various principal types of valve-gears. Eccentrics and shaft governors are also considered. The design of link-valves is discussed. The last chapter of the book is devoted to valves for steam turbines.

GOOD ROADS YEAR-BOOK FOR 1915. American Highway Association, Washington, D. C. P. 498. Price, $1.

A large amount of valuable information is contained in this book. The laws and systems of administration relating to highways in the various states of the Union are summarized, and considerable data on practice in foreign countries are also given. General specifications for the construction of the principal kinds of highways are given. There is a summary of road conditions in the United States and Canada. A bibliography is given, including the principal books on road-building as well as the various Government publications on the subject. Other parts of the book tell of college courses in road-building, a list of road associations, information regarding manufacturers of road material, and the constitution of the American Highway Association. One serious defect is the lack of a table of contents, the list which is called by that name being really an index.

ECONOMICS OF CONTRACTING. By Daniel J. Hauer. Vol. II. P. 334. Illustrated. E. H. Baumgartner, Rand-McNally Bdg., Chicago, Ill. For sale by *Mining and Scientific Press*, San Francisco. Price, $2.50.

The first volume of this useful work appeared two years ago. Volume II contains a large amount of new matter. It is probable that a larger proportion of contractors come to grief at one time or another of their business careers than of any other class of business men. A study of the present volume, written by a successful contractor, might prevent some of these failures. While the author lays considerable stress on the importance of cost records and estimating by analysis, other parts of the book are really more important, particularly because much has been written on cost-keeping during the past few years, while other equally important aspects of contracting have been almost neglected heretofore. One especially valuable chapter describes various methods for husbanding the contractor's funds until he can obtain payment for his work. Another chapter takes up the different classes of construction in turn and outlines a general plan for doing each job. Other parts of the book discuss handling men of all kinds from employees to public officials. Considerable space is also given to different phases of the law with respect to contracting. The book is badly in need of editing and condensation, two widely separated sub-heads in Chapter VI being 'The Liquor Evil' and 'The Drinking Evil,' but in general it will be found of great value.

PETROLEUM AND NATURAL GAS RESOURCES OF CANADA. By Frederick G. Clapp. P. 378. Ill., maps, plans, index. Department of Mines, Ottawa, 1914. Abstracts will be made in future issues of the PRESS.

New Machines and Devices

Information based on letters and catalogues from manufacturers.

A New Stopinig-Drill

In placing the 'New Cleveland' 2S stoper on the market, the Cleveland Rock Drill Co., Cleveland, Ohio, claims to be offering a stoping-machine which is a marked improvement over old and present types. The new machine embodies a number of changes in construction which, it is claimed, make for higher efficiency and greater footage.

The piston of this machine is only 2 in. diameter, which is a decrease in size over the standard machines. This results in a material reduction of air consumption. A marked increase in power is also claimed for this machine. This is accomplished by means of a valve which is faster than usual, together with an air-storage pocket in the hammer-head, which insures line pressure of the air when it gets to the piston, instead of a great reduction in pressure due to wire drawing and surface friction of air caused by taking the air through long ports with sharp turns. This reservoir is immediately behind the valve, and the air, when the valve shifts, not only reaches the piston instantly, but it maintains its pressure on the piston, until just before the piston hits the tappet. In older type machines, the air being choked, cannot fill the piston chamber fast enough to start it immediately, and does not maintain line pressure on the piston.

A shell-valve is used in this new device which is different in construction from the ordinary shell-valve, in that the piston goes completely through the valve and not into it. This makes the valve larger in diameter than the ordinary valve of this type and gives it a greater wearing surface, which, it is claimed, adds to the life of the valve and gives it a long continuance of its initial efficiency.

In the new stoper is used a tappet-seat. That is, instead of the tappet being seated in the hammer-cylinder, it is in a small forged part placed between the cylinder and the chuck. Ordinarily, the constant pounding slowly wears back the face in the cylinder, resulting in a constantly decreasing length of stroke, and a retarded reversal of the valve. The tappet seat is designed to reduce this to a minimum, the seat being made of forging which is hardened properly and uniformly.

The company has issued Bulletin 35 describing the new machine.

Valves at the Exposition

One of the largest and most artistically arranged exhibits in the Palace of Machinery at the Panama-Pacific Exposition is that of the Crane Co., of Chicago. The booth is 63 by 63 ft. The principal entrances are marked by arches, the legs of the arches being joined into railings comprising various sized valves, fittings, and specialties made by the company. The main entrance is 19 ft. high, made of an 18-in. cast-steel header, a 20-in. welded-steel header, and a proportionate 'U' bend below. Inside the railings are the following: a 72-in. cylinder-operated gate-valve weighing 57,000 lb.; an ⅛-in. brass valve weighing two ounces (between these two extremes the firm makes all sizes of valves for every purpose), a 48-in. back-pressure and exhaust relief valve, weighing 14,000 lb., a motor-operated 24-in. gate valve, pipe bends, drainage fittings, flanges, blow-off cocks, check-valves, whistles, tees, elbows, malleable-iron fittings, brass globe valves, steam traps, expansion bends, fusible plugs, safety-valves, and a host of other fittings used in mining.

Commercial Paragraphs

The Burd High Compression Ring Co., Rockford, Illinois, has increased its capital from $50,000 to $200,000. Increased business is said to be the reason.

A 5 by 10-ft. adjustable quick-discharge tube-mill of Chalmers & Williams, Chicago Heights, Illinois, make has been purchased by the California Slime Extraction Co. of Sutter Creek.

Mine hoists is the subject of Leaflet No. 13 of the Lidgerwood Manufacturing Co., New York. The particular hoist described stands 2 ft. 3 in. high. The drum holds 1000 ft. of ⅜-in. rope and 800 ft. of ½-in. rope, and is equipped with either a 5-hp. alternating or direct-current motor.

The Sullivan Machineey Co., of Chicago, has sent us Blue Booklet No. 115 on Sullivan air-compressors; Bulletin No. 34-U, giving instructions for installing and operating 'Chicago pneumatic' class N-SO fuel-oil driven compressors; and Bulletin No. 66-G, second edition, describing Sullivan air-feed stoping-drills, 'DF-21,' 'DA-21,' and 'DG-21.'

Bulletin No. 42,552, entitled 'Motor-Generator Sets,' has just been issued by the General Electric Co., Schenectady, New York. It is an attractive publication of 28 pages, inclosed in a designed cover and containing numerous illustrations of various types of motor-generator sets designed and manufactured by that company. There is included a general description of this type of apparatus.

The Round Mountain Mining Co., Nye county, Nevada, has just completed a pipe-line 45,336 ft. long to its gravel areas. The first section consisted of 14,000 ft. of 30 to 15-in. riveted steel pipe; second, 28,000 ft. of 15-in. lap-welded steel pipe; and third, 3336 ft. of 15-in. riveted steel pipe. Plain-end pipe, with bolted forged-steel joints, was specified for most of the line. Only 7550 ft. was of slip-joint design. The maximum head is 495 lb. per square inch. The installation cost about $125,000. The Western Pipe & Steel Co., of San Francisco, and Youngstown Sheet & Tube Co., Youngstown, Ohio, manufactured the pipe.

The Ingersoll-Rand Co., 11 Broadway, New York, has recently issued two new catalogues, Forms 3031 and 4034. The former is descriptive of the new Ingersoll-Rogler class 'FR-1' steam-driven, single-stage, straight-line air-compressors. The catalogue is profusely illustrated, showing the details of the machine in section. Among the principal features of construction may be mentioned the Ingersoll-Rogler air-valves in the air cylinder, and the balanced piston steam-valve, with automatic cut-off control, in the steam cylinder. The air-valves are silent in operation and long lived, operate entirely independent of any driving mechanism, and require practically no attention. The steam-valve represents the most approved design, permitting the use of the highest steam pressures and superheated steam. Form 4034 covers the type Bo. 36 Leyner-Ingersoll water-drill. This machine resembles the larger successful Leyner-Ingersoll drill, No. 18, but, it is, however, considerably lighter in weight, and intended for smaller diameter and shorter depth holes.

NOTES 973

PREFERENTIAL FLOTATION 974
More research is needed.

THE RAND AND THE WAR 974
Effect of the War on the development of a great gold-field.

METAL-SELLING METHODS 975
The selling of metals is largely in the hands of a few closely-allied firms.

MEXICO 976
Compromise and conciliation offer hope of a restoration of peace.

DISCUSSION

BOLTS AND NUTS.
By Millman 977
A practical detail.

ALASKA MINING LAWS.
By Maurice D. Leehey 977
Recording of power-of-attorney prior to making locations is not required.

PROFESSORS OF MINING.
By Thomas T. Read 977
Practical experience is of value in so far as it enhances teaching ability.

CONSTRUCTION OF UNDERCURRENTS.
By Calvin W. Haffey 979
How to decrease wear due to abrasion.

MIDAS MILL.
By B. P. Howell 979
Treatment rates are actually reasonable.

ARTICLES

PREFERENTIAL FLOTATION.
By O. C. Ralston 980
Separation of minerals that float can be done by special methods, varying according to the minerals to be separated. The various patents are reviewed and commented upon.

THE ALTAI REGION, SIBERIA.
By H. W. Turner 985
To the south and east of the Great Siberian steppe are the Altai mountains; in their foothills, at elevations from 1200 to 3000 ft., are rich mines of zinc and copper ore, containing gold in notable amount. Mining has been done for many years, but only recently have large companies begun to develop the deposits by modern methods on a large scale.

THE RAILWAY DOLLAR 993
From what it is derived and for what it is spent.

DEGREE OF CRUSHING TO FREE THE ECONOMIC MINERALS.
By D. P. Hynes 994
To separate mineral from gangue they must be in separate grains. Crushing is expensive, and the necessary limits may be determined by microscopic study of the crushed product.

MINING IN THE SHALE AT GOLDFIELD.
By J. K. Turner 995
The discovery of good ore in the contact zone between the shale and the latite has opened a new field for exploration at Goldfield. The ore channel is most likely to be found in depressions in the shale surface. As the contour is irregular, a complex system of development is necessary.

APEX LITIGATION AT GOLDFIELD 996
The main vein has a shape like a saucer. Locations on the outcrop possess extra-lateral rights that converge, like the sticks of a fan. The oldest location, the Booth, has the right-of-way over all subsequent claims.

EMPIRE

DRILLS

EMPIRE

It Is Possible to Insure Yourself Against Mining Losses

The formula is simple: Test your placer ground with the **"Empire"** Prospecting Drill, which will prove beyond question the value (or otherwise) of your property; work your placer ground with an **"Empire"** Gold Dredge—the only dredge specifically designed to meet the operation conditions as determined by this test. If your ground is barren, an **"Empire"** Drill demonstrates the fact at a nominal cost. If your property is rich, the **"Empire"** tells you **how rich,** and gives you the data which will enable you to raise capital. It also gives the data for the proper designing and building of an **"Empire"** Dredge that will return the largest possible profit on your investment. Consult us if you have a placer property to exploit or to develop, and we will suggest the proper method and equipment.

"EMPIRE" PLACER MINING EQUIPMENT

includes Dredges, Drills, Hydraulic or Bucket Gravel Elevators, High-Carbon Steel Sluices and Riffles, Hydraulic Pipe Lines, Giants, Etc. We design and build equipment to suit your conditions.

EDITORIAL

T. A. RICKARD - - - - Editor THOMAS T. READ - Associate Editor

AGRICULTURE and mining are not only the two basic industries, but they are intimately connected. When the farmer is prosperous there is money for mining. Crops this year are extraordinarily good. The rise in the price of wheat, due to the War, caused the farmers to increase their tillage by 6,000,000 acres. The wheat crop is estimated at the vast total of 950,000,000 bushels. While the price has dropped from $1.70, the price quoted before the expedition went to the Dardanelles and threatened to unlock the Russian store of grain, to $1.04 at this time of writing, yet 'dollar' wheat represents enormous wealth when applied to such a continental harvest. Something like $1,000,000,000 is involved. When this is garnered it should prove stimulating to the railroads, mines, and other industries of the country.

ZINC AND LEAD have fallen in price considerably since we wrote last. It is well that the unhealthy inflation should have been checked. From 26 cents zinc has dropped to 18 cents: concurrently lead has declined from 7¼ to 5½ cents per pound. Even these prices are, from the miner's point of view, magnificent. The recent sudden rise has disorganized many manufactures requiring these metals, and compelled a search for substitutes. For instance, the making of galvanized iron is almost prohibitive with zinc at 26 cents and copper at much over 20 cents brings aluminum into the field as a successful competitor. One man's food is another man's poison. Undoubtedly the rise in the price of the base metals that has already begun, and is likely to be maintained, despite necessary recessions, will upset many minor industries and cause readjustments of a disagreeable character. The cure will be a bigger production of the metals, in this country at least. To that we look forward confidently.

ALTAI is a name unfamiliar to many of our readers, yet it is a historic mining region that has come into considerable prominence in London financial circles during the last two years, on account of the operations of a group of American, English, and Russian capitalists, with whom several Californian engineers are professionally associated. We publish a general article on the Altai region by Mr. H. W. Turner, a mining engineer and geologist requiring no introduction to the readers of this paper. Lead, zinc, gold, and silver are the metals sought and found in the Altai mountains. The conditions for work are highly favorable. Transport by water is available, and if railway communication is as yet incomplete, that is a defect now in course of being remedied. The Altai reminds the traveler of the Rocky Mountains, more particularly the park areas of Colorado. Life is rendered wholesome by productive agriculture and varied farming, it being a fact that eggs and butter from this remote part of Siberia find their way to the markets of Petrograd and London. After the War, this region is likely to attract considerable attention, for the enterprises already started, notably the Irtysh and the Russian Mining corporations, promise to be highly successful. Further expansion of Anglo-American enterprise in this part of the world should afford an opportunity and a market for mining engineers and mining machinery emanating from San Francisco.

SMELTER CONTRACTS are attracting attention in the Coeur d'Alene. The contract between the Hercules Mining Company and the American Smelting & Refining Company expired on May 30. The mining company asked for a rate of $14 per ton for freight and treatment, full New York price for 90% of the lead and 95% of the silver, but as the smelting company proved unwilling to cede these terms, the mine was closed down, pending further negotiations. The Hercules, controlled largely by Mr. Harry L. Day, is one of the sweetest things in mining, for it is able to yield a large tonnage of 60% lead ore containing an ounce of silver for every unit of lead. In many respects it is the handsomest lead mine ever uncovered by the miner's pick. Exactly a month after the Hercules contract expired, that of the Sierra Nevada Consolidated, in the same district, also came to an end, and it likewise was not renewed because less favorable terms were offered by the smelting company. The chief mine in that part of Idaho, the Bunker Hill & Sullivan, is interested in the contracts of its neighbors, for if a concession is made to them, it also is entitled to better terms. The Bunker Hill contract was made for a period of 25 years, subject to modification every five years, and one of these intervals has just closed. The contract was acquired by the American Smelting company when it purchased the Tacoma plant, to which the Bunker Hill ore used to go before that smelter was changed from a lead to a copper basis, 10 years ago, soon after it was transferred to its present owners, who then diverted the Bunker Hill ore to the Selby and East Helena smelters. The local papers in Idaho talk about a tacit agreement between the various ore-purchasing companies whereby the American Smelting company obtains a clear field in the Coeur d'Alene, but it is a fact that the International Smelting company, with its plant at Tooele, in Utah, has cut into that preserve, or tried to do so, hence it conveys a wrong

impression to state that the American Smelting company has had, or has now, no real competition. We understand that Mr. Edgar Newhouse, representing this company, is now in Idaho with a view to arranging a new schedule with the mining companies mentioned, and others.

Preferential Flotation

No process is of greater present interest or more in need of further research than flotation. We are glad therefore to be able to present to our readers the results of investigations conducted at the University of Utah by Messrs. O. C. Ralston and D. A. Lyon. The special phase of the subject to which Mr. Ralston has devoted his attention is of much importance, for while flotation may be used to recover sulphides from the enclosing gangue, it is equally essential to be able to separate the different sulphides so that they may be treated separately. Encouraging progress has been made, and it is essential that the numerous investigators should be familiar with what has been accomplished, so that they may devote their energies toward making fresh discoveries rather than to the re-discovering of things already known or discarded. An example of this is seen in the patents by Ramage, cited by Mr. Ralston, in which a process is described that involves the roasting of an ore containing pyrite, chalcopyrite, and sphalerite at a temperature below 600°C. to cause alteration of the pyrite, then floated, roasted again at 700° C. to alter the sphalerite, with subsequent flotation of the unchanged chalcopyrite. The first impression is that this involves an impossibility. Chalcopyrite is generally assumed to behave much like pyrrhotite, which begins to roast at a temperature of 325°C., if finely divided; therefore its persistence unchanged at a temperature of 700°C. is incredible. The first essential is, of course, to check the investigation to see if the action described really takes place and, if found to be authentic, the causes of such a remarkable action should be investigated, as they may have an important bearing on possible modifications of the process. One difficulty likely to beset the critical study of flotation is that so far the engineering schools of this country have made little effort to train men for investigation and research, the emphasis having been placed almost wholly on routine work. Thus not a little work has been done by men who had no adequate preliminary training for the task. In the works laboratory, it is commonly impracticable to separate a process into its elements and study the effect of varying conditions on that one element; where a number of factors have to be simultaneously considered, research is difficult, for the effect of a variation on one factor may be in one direction, and in the opposite direction on another, or an accidental effect may be produced that obscures the real effect. Thus an experienced investigator may draw entirely different inferences from the results of an experiment than would be deduced by one who considered only the single factor under investigation. There must be a large number of engineers who have great natural aptitude for carrying out the commercial research that is so marked a characteristic of today. Unfortunately no method is available for determining this aptitude beforehand. In this, as in other lines of industry, it is desirable to select the right man for the work.

The Rand and the War

The Central Mining & Investment Corporation is known to most of our readers as the London agency for transacting promoting business on a large scale and a big financial organization controlling a group of the most important mines on the Rand. In effect, it has inherited the mining business of Wernher, Beit & Co. In 1914 the mines controlled by this corporation in the Transvaal yielded 60% of the total dividends and 37% of the total gold output, which was $177,940,000. Thus this organization was responsible for 14% of the world's total gold output, and this does not include its operations in other regions, notably West Africa. The total reserves of ore in the corporation's South African mines is estimated at 35,000,000 tons, averaging $6 per ton. At the recent annual meeting, the chairman, Sir Lionel Phillips, mentioned the fact that $2,700,000 of the corporation's investments are in the form of German and Austrian government stocks, while a cash item of $885,000 more is tied up in Germany, whither it was sent in anticipation of dividends payable to German shareholders. Moreover the corporation owns $6,250,000 of British Treasury bills. The total cash available represents $10,000,000. On the investments in "enemy countries" the chairman allowed a depreciation of 30%. A large holding in De Beers diamond shares has suffered, as has other property, yet Sir Lionel was able to summarize the position by saying that the assets were worth $86 per share, with liabilities of $36, so that the present value is $50 per share, of 425,000 shares. In his frank and comprehensive survey of the corporation's affairs, more particularly in relation to South Africa, he referred to the fact that the public debt of the Union of South Africa would be increased by $75,000,000 to $100,000,000 by the War, more particularly the campaign in German South-West Africa. The Government of the Union has made a special levy of $2,500,000 on the mining industry, besides a sum of $1,715,000 that falls to it by way of mining revenue, from *bewaartsplaatsen*, or dump-sites. However it is not the gold-mining industry but the diamond mining that has suffered most. The diamond mines are closed down, and another industry in which many of the mining engineers and operators had participated largely, namely, ostrich farming, has been hard hit. The result may not be all bad, for much good agricultural land has been diverted to the production of ostrich feathers, a product not nearly so useful to the community as crops of grain. In South Africa, as in Europe, the War has developed organized paternalism, the exigencies of an abnormal period causing the Government to undertake responsibilities usually left to individual or to corporate effort. It is interesting to note that the Union of South Africa is one of the few governments that owns large

areas of gold mining ground. Most of this is in the eastern end of the Rand and covers about 80,000 claims, equal to about 117,500 acres. Already it has a big interest in the Premier diamond mine and in the Government Gold Mining Areas, the latter being in that eastern part of the Rand to which we have just made reference. In that locality is the Brakpan mine, and near-by is the Modderfontein, probably the greatest gold mine in the world today. Concerning the unworked area, still owned by the Government, it cannot be said how good it is or what portion of it is workable. In this Far East Rand, as it is called, the gold-bearing formation, known as the Main Reef Series, is at a vertical depth exceeding 3500 feet, and to test the ground it becomes necessary to sink shafts at an expense, say, of $750,000 to $1,000,000 per shaft. For safety, they must be sunk in pairs. Diamond-drilling in the ordinary way is unsatisfactory, the evidence of bore-holes having proved illusive. The distribution of the gold is too irregular and the proof of quantity, that is, tonnage of ore above the economic limit as to grade, is too essential to justify the launching of any scheme involving millions of pounds, not dollars, without the assurance obtainable by the actual reaching of the lode by means of shafts. Therefore, it is incumbent upon the Government, especially at this time, when gold is so pre-eminent an asset, to welcome large-scale exploitation by offering terms on which sagacious men will be justified in finding capital for the necessarily expensive and elaborate exploratory work, without which this large tract of gold-bearing ground must remain unproductive.

Metal-Selling Methods

An interesting case involving trading in metals has been concluded at Adelaide, South Australia. On December 12 proceedings were commenced by the Federal Government against Francis H. Snow, a well-known metal-buyer, on the charge of endeavoring to trade in copper with his principals, Aron Hirsch & Sohn, in Germany, after war had been declared. On May 14 the Judge directed the jury to return a verdict of 'not guilty,' because his attempts to trade had taken place before the passage of the Trading With The Enemy Act. Here we have a disproof of the adage that *inter arma silent leges*. It is well sometimes that justice should be blindfolded. War is abnormal; it is desirable to limit its power to disrupt the contracts and conventions of individuals as made in time of peace. This case, however, has proved important in that it disclosed the extraordinary interlocking of interests between the metal-brokerage houses. Whether doing business at Frankfort, Halberstadt, Rotterdam, London, New York, Melbourne, or Adelaide the ramifications of a complicated trade were shown to be controlled by a relatively small group of non-national metal-merchants. If the members of this group are mostly German, as they are, it is yet a fact that some of them are English and some American, so that the question of nationality does not arise in the present discussion. We are looking at the subject as it affects the metal-producing mining companies and operators facing a clique of metal buyers and speculators, who have an excessive and dangerous control of the approaches to the European market. In the course of the Snow trial a number of letters were read before the Court, disclosing the defendant's correspondence with sundry well known metal-brokers. We need not give their names, because it is not our purpose to attack any individual or firm but to warn the controllers of mines against the unhealthy condition of their selling arrangements. Some of these metal-dealers trade under two or three names, as subsidiary companies. Others, by participating in the business of firms distributed at various centres, are enabled to create a false impression of competition.

One specific case we can quote, namely, the European zinc cartel, or syndicate, which, before the War, had absolute control of the market and used that control outrageously. This cartel consisted of four ore-purchasing firms, three of which were German and one Belgian. They combined to regulate the market for Broken Hill zinc concentrate. Keeping on hand a large stock of zinc, they were able to hold the price down, by the mere threat of dumping ten or twenty thousand tons of spelter on this market whenever required to check American production. Their London representative regulated the price. If a manufacturer in the Midlands wanted spelter, he came to London to buy. When he placed his order with a broker, he was told there was no metal to be bought. Ultimately he came in contact with the agent of the cartel, who would impose a long-time contract. The manufacturer would express willingness to pay the market price. To this the cartel's agent would demur, insisting on the quotation at Berlin, not in London. Thus the miner sold on London and the consumer bought on Berlin, the latter being absolutely in the hat of the cartel. Consequently the consumer in England paid from 10 to 40 shillings more per ton for zinc than the quotation in London on a given day. He could not kick, because he found himself unable to get metal elsewhere. Obviously, the contracts of the Australian mining companies in final settlement should have been at the price on which the metal *is sold,* not the average price on any metal exchange. Many of the Broken Hill companies were victimized. These facts were disclosed in connection with plans to erect a zinc smelter, when the former agreements with the Belgian smelters came to light. Sub-contracts between the metal-brokers and the smelters in Belgium showed a difference averaging fully 20 shillings per ton in favor of the agencies. The fact became clear that the members of the cartel made their money not by brokerage but by these differences in price.

It may be asked, how is this sort of thing to be stopped? Is it not a feature in kindred industries? So long as men can put their heads together and get control of the marketing of any product, they will do so. Laws may be enacted, but their scope is limited by national boundaries. Nor do we wish international trade to be checked; on the contrary we want to see it expedited, but not at the expense of fair dealing. Obviously, the only remedy is for the producers of the

metals to do their selling through the medium of brokers that do not deal on their own account. It is the old story of the broker that speculates, until he finds it profitable to play both ends against the middle. Another remedy is for metallurgists or engineers to study the business and place themselves in a position to act as specialists in the matter of ore and metal contracts. Some have the knowledge and experience necessary. Their services should command a big retainer. It is an urgent matter, for it involves the marketing of an enormously rich produce, in the winning of which great skill is spent only to have the fruition of the effort spoiled by sheer ignorance at the conclusion. The metal industry needs brokers that do not speculate and engineers that understand the business of marketing. Mining companies must place the selling of their metallic products in the hands of competent persons in their own employ.

Mexico

We presume that no apology need be made for our frequent comment upon the trend of affairs in Mexico. The subject is one of deep concern to most of our readers, for the lack of orderly government in that distressful country has driven many members of our profession from their posts; it has caused loss of production and property to mine-owners and companies; it has closed one of the best markets for American machinery and the various supplies required by a highly complex industry. Indeed, while the colossal tragedy in Europe overshadows the Mexican quarrel, as the revolutionary conflict in Mexico eclipses the recurrent Yaqui uprising, yet the effect of the events following the enforced resignation of Porfirio Diaz has been of more immediate injury to most of our readers than the Armageddon across the Atlantic. To those living on the Pacific coast, with wide and varied interests in the mineral development south of the Rio Grande, it is a matter of acute moment whether order can be restored there or misrule rendered chronic.

President Wilson's declaration of June 2 has elicited a response from the leaders of the two principal factions. Both talk about their dignity: a sign that they expect to be compelled to make concessions. Francisco Villa appears the more amenable, expressing willingness "to invite a new union of all Mexicans to work together to insure the triumph of the revolutionary principles." He declared his respect for President Wilson and acknowledged "the moral aid given by the people of the United States" in the overthrow of Huerta. This was on June 12, just after his defeat by Alvaro Obregon at Leon. A week later, on June 19, his military prospects looked more cheerful, whereupon he became less docile. He sent a note to Washington asserting that "the only hope for Mexico is that your government recognize the faction which I represent. We alone can bring peace and prosperity to Mexico." Meanwhile Venustiano Carranza replied to President Wilson's *pronunciamento* by "a proclamation to the people" in the course of which he asserted the right of his party to recognition by the United States and other foreign governments. Lack of such recognition, he insisted, was the one difficulty preventing a restoration of constitutional government in Mexico. Since then he is reported to have quarreled with his principal commander, Obregon, and with four members of his cabinet. Indeed the quarrel has gone so far as to menace his life and cause his retirement to the fortress of San Juan de Ulloa, the famous island off Vera Cruz. This has caused a halt in the march of Pablo Gonzales, who is leading a body of Carranza's troops toward Mexico City. At the same time the Yaquis are on the war-path in Sonora and an American warship is on the way to Guaymas with a view to landing a force of marines for the protection of American settlers in that region. Against such interference General José Maytorena, who is Villa's representative in Sonora, protests, despite the fact that a force sent by him against these Indians has been defeated. The whole position, obviously, is highly complicated, but it is one that may be simplified shortly by the logic of events.

Already suggestions for a compromise candidate to the presidency have been made. The Villa-Zapata combination was reported, on June 15, to favor Manuel Vasquez Tagle, the one member of Madero's cabinet that neither resigned nor took part in the subsequent strife. He is now in this country. Another name mentioned is that of Felipe Angeles, Villa's chief of artillery; but he is, in many ways unsuitable. Indeed no strong partisan of either Villa or Carranza is likely to be able to win the general support of all warring factions. Representatives of the Villa-Zapata party are reported to be on their way to Washington, to confer with the President. This is a manifest acknowledgment of his moral influence.

It is clear, moreover, that the President's policy has passed from non-recognition, in itself effective as against Huerta, to peaceful intervention, now under trial. The third alternative is military intervention. This last, it is hoped, will not be necessary, but the course of events may easily bring it within the range of practical politics. The Mexican tangle must be unraveled before the European war ends. As we see the position, it is imperative that both Villa and Carranza be eliminated; both are impossible, because neither is able to rally the general support of the people. Some Mexican of good character, not too closely identified with either faction, must be supported in an effort to unite the discordant elements that have brought the country to ruin. Signs multiply that the Mexicans, outside the small bodies of marauding soldiery, are sick of the pillage and devastation. Famine stares them in the face. The purpose of the fighting has ceased to be clear. The two parties now in conflict profess equally liberal principles and exhibit equally sanguinary motives. Both claim to be the political heirs of Madero and his reform movement. Given a third party, able to absorb both the Constitutionalists and the Conventionalists under a respectable chief, it ought to be possible to end this protracted period of misrule. Recognition from Washington, together with financial support and an embargo on arms, should serve to consolidate a compromise government and enable it to restore peace over the major portion of Mexico.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment

Bolts and Nuts

The Editor:

Sir—Having received benefit from your paper, I would reciprocate, if possible, and therefore suggest that others might profit by a suggestion made to me by a mechanical friend many years ago, as follows:

In putting machinery and fittings together nearly everyone screws the nut on the bolt with the flat side bearing against the surface upon which it is being screwed down. Except in the case of machined nuts, you can readily perceive that more tension can be put on the bolt with less muscle, if you reverse the usual practice and place the rounded side down. Punched nuts are always rough on the under side, and when it commences to get tight, the irregularities dig into the surface on which they are being turned and the frictional resistance is increased so much that I have frequently seen threads stripped off when a bolt is only moderately tight. Moreover, it holds better, as the vibration gradually pounds down the projecting parts and the bolt gets loose and then you have a two-man job either tightening it or replacing it. One man and a wrench to hold the head of the bolt and another man and wrench on the nut, and both swearing.

I have just been over some 240 bolts on a machine that has been working some 30 days; several had threads stripped, and about 10 had threads worn off from playing in the holes; and the nuts had not turned on the bolts either.

MILLMAN.

Knob, June 7.

[Practical hints such as these are always welcome.—EDITOR.]

Alaska Mining Laws

The Editor:

Sir—In the Alaska news of your last issue, referring to the new mining law passed by the Legislature, you say that

"Claims may not be staked by power of attorney in future, unless that power has been recorded in the recording office of the district where the claim is staked, and before the staking of the claim."

The new law does not require record of the power of attorney "before the staking of the claim," as you say. Section 6 of the new act, approved April 20, 1915, provides that

"Such power of attorney be duly executed and acknowledged before an officer authorized to administer oaths and recorded in the office of the Recorder of the district in which such claim is located, prior to the date of the filing for record of any location thereunder."

You are correct in stating that this is the outcome of the Chisana litigation. It was there contended by the 'jumpers' that the Congressional Act of August 1, 1912, required the record of a power of attorney before the staking of the claim. My contention on behalf of the original locators was that the locations were good because of the record of the power of attorney at the same time with the location notices and before intervening rights. This position was sustained by Judge Brown in his decision, and evidently by public sentiment in Alaska, as you will note the new Mining Act clearly expresses this and makes it the law of the territory. The new law also adopts a suggestion of Judge Brown that such record be required in the recording district where the location is made instead of in any recording district in the Judicial Division, as the Congressional Act required.

MAURICE D. LEEHEY.

Seattle, June 12.

[We referred to the new enactment in our editorial columns last week.—EDITOR.]

Professors of Mining

The Editor:

Sir—The letter of Ross E. Browne, published in your issue of June 12, on this subject is exceedingly interesting. The views of an engineer of such distinction who has himself had experience as a professor deserve the most careful attention. There is, nevertheless, advantage to be gained from a multiplicity of opinions, and I should like to trespass on your space in order to express my own views, also derived from teaching experience, on some of the points involved.

As a major premise it may be assumed that the first essential for a teacher is to be able to teach. Teaching is an art, and, like music, is one that can be successfully cultivated, but only on the basis of a natural aptitude. Curiously enough, this essential feature is commonly overlooked: in several years of teaching experience I only once heard of a candidate being examined as to whether he could teach. The usual method is much the same as if a candidate for *prima donna* of an opera company were questioned as to what she knew of the theory of music, with what teachers she had studied, and how many concerts she had attended, but without trying her voice to see whether she could sing. Possibly it is as-

sumed that teaching is such a simple matter than anyone can do it with a little practice, but this is not at all true, and a critical study of the teaching methods pursued in the representative engineering schools will quickly disclose the fact that they are a very long way indeed from perfect.

The common mistake made by teachers of engineering is in assuming that the purpose of education is to convey information, whereas it should be the development of power. A student who desires information and can read the English language, can, for less than the cost of one year in college, buy a hundred of the latest books on mining and metallurgy, and find in them more information than he can absorb and learn how to utilize during the rest of his life. What his college training should, but too often fails to, give him is the power to apply the information which is everywhere available in abundance. Mr. Browne says that when he graduated from Freiberg he "found himself ignorant of all useful work around the mines." Judging from the use he has made of it, the presumption is that his Freiberg training was excellent, though perhaps, through natural ability he would have been a successful engineer even if he had had no training at all. At any rate, I submit that a well-trained graduate must necessarily be ignorant of the details of useful work around mines and smelters, except such relatively simple and universally applicable matters as surveying and chemical analysis. The variety of work involved is so great that it is absolutely impossible to teach it to the students, and it is equally impossible to determine what the student may be called upon to do. A metallurgical engineer retained by the largest financial interests in this country not long ago told me that his most recent tasks had been to pass upon the advisability of developing a hydro-electric enterprise and the mechanical feasibility of a wave-motor. If this man had been merely a trained metallurgist, he would have failed utterly, but he was a man of mental power and successfully performed the task. This is an extreme case, but the principle is generally true. There has been too much emphasis placed on practical training in engineering schools, and too little emphasis on the development of power, and this, in my opinion, is sometimes due to the employment as teachers of men of practical knowledge who are not skillful teachers. The leading educators are well aware of this, and Nicholas Murray Butler not long ago said, "It is to be regretted that neither within nor without the universities is there any public sentiment that justifies the dismissing of a professor on the mere ground that he cannot teach."

While generally agreeing to these considerations, Mr. Browne concludes, like Galileo, by asserting that a teacher must have had practical experience. It is desirable, therefore, to inquire as to what constitutes practical experience, and in what way it conduces to efficiency in teaching. Practical experience, I suppose, is the actual doing of work. On this basis a man who had worked ten years in one mine would have good practical experience; a teacher who had spent ten summers visiting the principal mines of the country and attentively studying their methods would be devoid of practical experience. But I do not think anyone will seriously disagree with me that, quite aside from relative ability, the teacher would be in a much better position to instruct young men in the principles of mining, because he is familiar with a great variety of methods and has been at pains to learn the reasons therefor, while the man of practical experience knows one method in detail and too often has given little thought to the fundamental considerations governing its adoption. I have often been struck with the fact that comparatively few men gain from their practical work a thorough understanding of the principles involved. Often in visiting mines and smelters I have been told by the manager, "I am too busy to go with you just now, but I will send Mr. X, who has a good knowledge of the details." Passing out into the plant, I frequently found that Mr. X was unable to answer my questions; he could tell me what they did, but not why they did this or that rather than something else, which I had seen practised elsewhere. Many companies, indeed, seem to prefer that subordinates shall not obtain too much understanding of the general principles of the business, possibly in the fear that they may later take it with them to competitors. Practical experience, to my mind, is the knowledge of actual operating conditions gained in the field, as contrasted with knowledge gained from books and technical journals. It is much easier to gain this practical knowledge by visiting and carefully studying the operations at a greater number of plants than it is by working in one or two. In addition, at the end of two or three years of teaching, the man who derived his practical experience from work would be in just the same position as the teacher, for practice at the places where he worked would have changed, and he would have to visit the plants to familiarize himself with the changes that had taken place meanwhile.

Another disadvantage of working experience is that it fills a man too full of details and when he tries to teach he is apt to be in the sad case of the centipede that fell into the ditch through trying to count his feet. A glance back through the files of the Mining and Scientific Press will serve to illustrate this. It will be seen that the most lucid and comprehensive articles describing the work at a mine or smelter have been written by visiting engineers and not by the superintendent or one of the engineers. To the latter the fundamental aspects of their work are as obvious as the climate or the weather, and it does not occur to them that one who knows nothing about the place must have them explained to him. In other words, they make the same mistake so commonly made by teachers of supposing their audience able to perceive the fundamental relations once the details have been stated. As a matter of fact, the reader, and to a much greater extent the student, is quite unable to perceive these general relations for himself; they are the things that above all need to be explained. This brings me back to my original statement, that the first essential for a teacher is to be able to teach, and teaching is an art in which few excel.

One other point is of vital importance in selecting a

teacher, but I have used up so much space that I cannot do more than introduce it with a quotation from Emerson: "In selecting human assistants, such superficialities as education, as physical strength, even antecedent morality, are not as important as the inner attitudes, proclivities, character, which after all determine the man or woman."

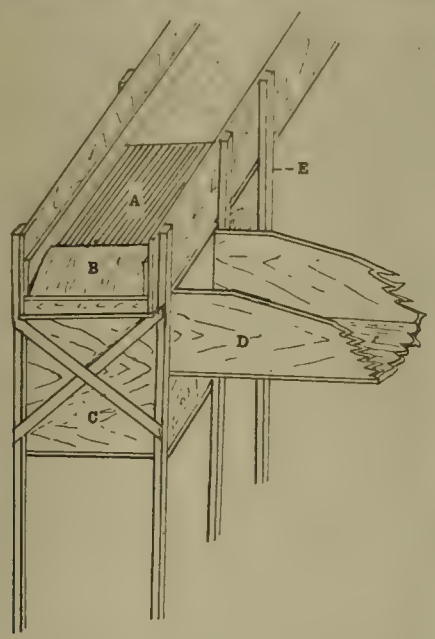
Construction of Undercurrents

The Editor:

Sir—Having read the article 'Construction of Undercurrents,' by Chas. S. Haley, in your issue of May 1, 1915, I am enclosing a sketch that I believe will be of interest both to your readers and to Mr. Haley. One of the objectionable features of undercurrents, the renewal of the throat-lining, is overcome by making the con-



ANOTHER FORM OF UNDERCURRENT.

struction as follows: Build the grizzlies far enough back from the end of the flume or sluice so that the water flowing through them will not strike the end of box *C* above water-level. At the end of the grizzlies *A*, board *B* with a steep pitch will provide for the disposal of the coarse material, which passes over the grizzlies. Box *C* should extend back as far as post *E*, which is placed at the beginning of the grizzlies. The principle involved is this: box *C* forms a reservoir below the level of the discharge into *D* and abrasive material will not come into contact with the wood, but will strike the water in *C*, thus preventing the wear on lumber. The necessity of lining *D* with sheet-steel, which is expensive when used to withstand the abrasive action of a heavy stream of water containing sand and fine gravel, is thereby obviated. The agitation due to the flow of water will be sufficient to keep the solid particles in suspension and they will be carried out of *D* by the water.

CALVIN W. HALLEY

Colfax, California, May 15.

Midas Mill

The Editor:

Sir—Supplementary to your notes on Elko county, Nevada, printed in the issue of May 29, quoting a correspondent in the *Tonopah Miner* concerning charges for ore treatment at the Midas custom mill, I should like to say that Rochester, having electric power, doesn't like Midas freight fuel-oil and all supplies over 30 miles of practically impassable Humboldt-Elko county roads.

The recovery obtainable on any particular ore is paid for, usually 90% of the assay value, in some instances as high as 95%. Treatment rates quoted apply to desultory and negligible quantities. Rates as low as in any camp of like conditions are given on lots of appreciable and regular or dependable amounts. I suspect that some time the *Tonopah Miner's* correspondent had a ton or so for which the Rex Reduction Co. cleaned the sampler equipment before and after handling, made a control-assay on the sample, and realized possibly sufficient to pay for the zinc necessary to precipitate the metal content.

Midas, Nevada, June 3. B. P. HOWELL.

BEEHIVE COKE-OVENS waste most of the valuable gases in coal. The Semet-Solvay by-product oven is a Belgian invention. From it are recovered many products, including coke, ammonia, sulphate of ammonia, tar, benzol, cyanides, gas for light and power, and several others. The process of making coke in a by-product oven differs in one essential respect from the beehive operation. In the latter the coal is charged into the oven and the coking takes place by means of air introduced directly into the oven chamber, so that all the by-products are destroyed. In the by-product oven the process is a true dry distillation. The oven chamber is filled almost full of coal and is sealed as tightly as possible to prevent the admission of air. The heat for coking is introduced by burning a portion of the gas produced in the distillation of the coal in a series of heating flues in the sides of the oven, the heat passing through the walls to the coal. Beehive ovens were formerly preferred here, on the ground that the coke is of better quality, but the use of by-product ovens is increasing.

THE LAW of Indiana requires oil and gas produced from wells to be safely and securely confined in pipes or other safe receptacles. Where persons have negligently allowed oil to escape from tanks insecurely hooped, and the oil flowed down a drainage ditch, took fire from live coals dumped from a steam-dredge, and burned the dredge, the former were held liable for the resulting damage. In such a case it has been held that the escape of the oil was the proximate cause of the injury, and that the accidental dumping of live coals from the dredge onto the oil was not an intervening cause.

Preferential Flotation

By O. C. RALSTON

*Introductory. 'Preferential' flotation is a specialized application of the flotative principle in the separation of minerals from their ores. It gained its first wide use as a name for certain methods of floating minerals in connection with the Horwood process mentioned below. 'Selective' flotation has come to mean (by common consent) the flotation of valuable minerals (generally the metal sulphides) in the presence of undesirable gangue-minerals. 'Preferential' flotation is the flotation of one of the ordinary selectively flotative minerals in the presence of another similar mineral. Thus, a mixture of galena and sphalerite can be floated 'selectively' from a gangue of granite, limestone, or other common gangue-material, while galena may be floated 'preferentially' from a mixture of galena and sphalerite.

On account of the great interest manifested in this subject of late, I have thought that the following review of proposed or operating processes might be of interest. This review is largely a compilation of patent literature, but it might be well to call attention to the fact that, at present, the patent literature is one of the best sources of information on the subject of flotation for one who does not have the opportunity to visit at first-hand the localities where the practice of flotation is being used or tested.

Cattermole. In 1904 Cattermole (U. S. Patent 763,259) made one of the earliest proposals for the preferential flotation of minerals. The method, as he described it, was not exactly a flotation method, but it involved most of the underlying principles of flotation, and hence is of interest in this connection. As stated by Cattermole: "The invention relates to the classification of the metalliferous constituents of ores which have been separated from gangue by oil or similar matter," and "consists in fractionally removing the different constituents from the agglomerated masses by freeing the constituents in turn from oil, and thus obtaining them in a separable condition by the use of emulsifying agents of varying strength and activity, preferably in conjunction with an alkali." "In carrying out the process, the metalliferous matter agglomerated by oil is mixed and agitated with a solution of an emulsifying agent, such as a soluble soap-alkaline oleate, for example, to which a certain proportion of soluble alkali, preferably caustic potash or soda has been added." "It is found that the minerals vary in their affinity for oil employed in the above manner, and thus by treating the oily masses or granules in the first place with an alkaline emulsifying solution of a certain strength, the mineral of least affinity can be separated therefrom, and by increasing the strength or modifying the proportions of the breaking down solution step by step, the various constituents can be thrown out in the order of their increasing affinities."

Cattermole's patent came at a time when the process was truly "oil flotation," as the use of small amounts of oil had not been made successful, and the particular method of flotation which he had in mind in this patent was probably that described in one of his other patents, in which the minerals desired were flocculated or granulated by the use of oil in larger amounts than the present methods of flotation, that is, in amounts up to 5% by weight of the ore, and these granules would sink of their own weight in an upward moving current of water, such as that of a classifier, while the unflocculated gangue would rise. He made the wording of his patent, however, broad enough to cover the treatment of products as obtained by true flotation.

As an example of the working of his process he uses an ore consisting of a silicious gangue, zinc-blende, copper pyrite, and galena, which has been treated with an oil for the granulation of the mineral sulphide particles, and the latter separated. The oil is preferably one that is not readily emulsified, such as a hydro-carbon oil, which will give a wide range of strength in the solutions used later in the breaking down of the granules. The compound granules are run into the first agitation apparatus where they are agitated with a solution containing, say, 0.75% soap and 0.75% alkali, by which the zinc-blende is "dropped out." The remaining granules are passed into the next similar apparatus, in which a solution containing 1.5% soap and 1.5% alkali is used. Here the copper pyrite is freed and only the granules of galena remain. As Cattermole proposed the use of so much oil, it had to be recovered by the use of strong alkali solutions.

The rules for proportioning the solutions took into account the fineness of the ore, the relative proportions of the minerals, their physical condition and chemical composition, also the kind of oil and emulsifying agents used, and the alkali selected. The finer the ore the more compact and cohesive the granules formed, and hence the stronger the solution required to break them down. With granules largely of galena which break down with difficulty, stronger solutions are necessary than for those consisting mainly of sphalerite. With animal or vegetal oils that emulsify easily the breaking down of the granules will be too rapid for convenience. The heavy residuum oils and the heavy hydro-carbon oils are the best. Oils may be blended advantageously for this purpose. An alkaline solution of the oil used in granulating is best for emulsifying.

Whether Cattermole's process was ever applied or not is not known to me, but it is not impossible that its principles may be applied to modern flotation froths.

Wentworth. Following the U. S. patents in their

*Contributed by the Department of Metallurgical Research, University of Utah. D. A. Lyon, metallurgist in charge; O. C. Ralston, assistant metallurgist. Published by permission of the Director of the U. S. Bureau of Mines.

chronological order, the next is No. 948,732, of 1909, taken out by H. A. Wentworth and assigned to the Huff Electrostatic Separator Co. It "relates to the separation of the ingredients which constitute ore mixtures, and particularly to the separation of sulphide ores from each other." "The process consists in the preliminary treatment of ore mixtures containing several sulphides, which converts some of the sulphides, superficially at least, into metallic compounds which are differentiated in their behavior" with respect to flotation processes as commonly practised. To use the words of a later patentee, the surfaces of such minerals as galena, pyrite, and chalcopyrite are "deadened" by a very short and slight roast in a roasting-furnace, while the sphalerite is unaffected. Thus the sphalerite can be removed by flotation from such an ore, leaving the other sulphide minerals to be removed by other means. A few minutes heating at a dull red heat has been found to be sufficient.

This is a type of process that has been tried in Australia under the name of the Horwood process. It is further described under that heading in this paper.

RAMAGE. The same idea underlies the next patent, which is No. 949,002, of 1910, taken out by A. S. Ramage and assigned to the Chemical Development Co., a Colorado corporation. "This process has for its object the separation of the valuable minerals from such ores as chalcopyrite, bornite, or erubescite, and mixtures of the same with pyrite, in which ores the copper is in chemical combination with the iron; and also from such ores containing zinc-blende. The method is also applicable to compound ores, such as those of the Cobalt district and other sulph-arsenides." "The principle of the process is founded on the combination of fractional roasting with chemical floating." Ramage's introduction of the term "fractional roasting" is particularly felicitous, as it more accurately describes the method than does the term "preferential flotation," used by Horwood.

Ramage described the process by the use of three examples, which are decidedly interesting. The first example is of an ore containing iron pyrite and chalcopyrite, with a content of about 5% copper and 30 to 40% sulphur. The ore is roasted at about a red heat long enough to decompose the pyrite slightly and not affect the chalcopyrite. "The burnt ore is then crushed to at least 15 mesh and passed through a solution of acid sulphate of soda and nitric acid (the solution being formed by adding nitric acid to sulphate of soda), which solution is kept near the boiling point. The copper sulphide immediately rises to the top of the bath and can be skimmed off." The copper dissolved in the bath can be recovered in known ways. This method of flotation (hot acid bath) is not new, having been patented by De Bavay, Potter, Delprat, and others. The fractional roasting had been previously patented by Wentworth and so the only thing that seems new is the combination of methods.

A second example is that of an ore containing pyrite, chalcopyrite, and zinc-blende in quantity. The ore is roasted at a temperature of not over 600°C., so that only the iron pyrite is deadened. The roasted ore is then subjected to the acid sulphate of soda solution for flotation of the unchanged sulphides of zinc and of copper. This product is then roasted at about 700° C. until all of the zinc sulphide is decomposed and the copper sulphide unchanged. This mixture is treated with a solution of dilute sulphuric acid for the dissolution of the zinc to be recovered from solution by any familiar process, such as electrolysis, and the copper sulphides sent to the copper smelter. There are certainly most interesting facts disclosed in this patent. The great resistance of copper sulphides to the roasting process, as compared to the sulphides of zinc is something new and will be a most valuable characteristic, if true.

The third example is that of the ores of the Cobalt district, Canada, where cobaltite, niccolite, chalcopyrite, pyrite, and native silver occur. All the sulphide and sulph-arsenide minerals are floated, leaving the silver in the gangue. The sulphides are roasted at about 800°C. and everything is decomposed except the copper sulphide, which can be floated from the calcine. Again we have mention of the almost incredible property of copper sulphides to resist roasting.

The next patent was that of H. A. Wentworth, amplyfying on his former patent in claiming the superficial chemical change of minerals as a method of separating them preferentially by flotation. He had in mind particularly the treatment of the ore with chlorine, which would act superficially on some of the minerals so that they would sink when subjected to a film-flotation process, while others would have their flotative properties enhanced. As an example, a mixture of zinc and iron sulphides when treated with chlorine gas in a slightly damp state, is so altered that the zinc sulphide will float on a film-flotation machine much better than before treatment, while the pyrite has a coating formed over its surface, which is much more easily wetted, so that it will sink. Still a further example is the application to the separation of pyrite and chalcopyrite. Chalcopyrite is attacked much slower than pyrite; hence it can be floated in its presence. A similar behavior of the minerals is observed when they are suspended in water containing dissolved chlorine in the proper concentration, but the best work seems to be done with minerals fed onto one of the film-flotation machines, such as that of H. E. Wood of Denver, although Wentworth gives the design of one of his own in the specification. It is easy to see that with chlorine-water and one of the mechanical frothing methods of flotation the soluble coatings that are formed on the surfaces of the minerals would be simply washed off and the preferential part of the flotation lost. Tests in our laboratory seem to show this. So far as is known to me, this process is not being used.

HORWOOD. This process of preferential flotation is practically the same as that described under Wentworth and Ramage. It has been worked for some years in Australia and received careful testing by the Zinc Corporation. It depends upon the 'deadening' of galena and pyrite in a short roast at 300 to 500°C., whereby the galena is coated with lead sulphate and the pyrite with iron oxide, while the sphalerite is unaltered. This allows a separation of the undesirable zinc from the lead-iron-

silver product and allows their separate marketing. This process has received more careful attention than any other process and reference to original articles is best.† According to the data given in some of this literature, it appears that it is possible to take a flotation concentrate containing 36% Zn, 15% Pb, and 22 oz. Ag per ton, and divide it into a zinc product running as high as 50% Zn, 7% Pb, and 15 oz. Ag, and a lead product containing 38% Pb, 8% Zn, and 42 oz. Ag per ton. This is of great interest to all producers of 'complex sulphide' ores, as the milling of coarsely crystalline material has presented much difficulty in the past for the reason that some finely divided material (slime) is bound to form in crushing, and while the combined lead and zinc sulphides can be floated nowadays without much difficulty, the mixture is of far less value than the two minerals separated. This is important enough, not to speak of the possibility of treating the microcrystalline sulphide ores and those containing gangue of high specific gravity, such as barite. While flotation has been a boon to the concentration of all sulphide slimes, preferential flotation is much more important for the ores containing undesirable combinations of sulphides. Hence Horwood's work should receive the highest praise.

Another detail, as regards this process, is that 35 lb. of sulphuric acid per ton of ore is necessary and 2 to 3 lb. of oleic acid for the flotation of the unaltered zinc. All of this appeared in Horwood's first patent, No. 1,020,353, of 1912, and he later came out with improvements on the process in Patent No. 1,108,440, of 1914. In this later patent he stated that he had found there was a tendency for the silver to follow the zinc, which is undesirable, but that this could be prevented by simply washing away all soluble salts on the concentrate before it was subjected to the deadening roast. This reduces the amount of oxidized zinc formed, and lost by solution in the dilute acid in the mill-water, as well as allowing the silver to become deadened to a greater extent. He also found that the most successful flotation took place with the pulp at a temperature of about 120°F.

It will be seen that the Horwood process has been applied only to concentrates from previous flotation or from other concentration processes. This is the logical place to apply it, as there is no object in leaving a non-flotative galena or other sulphide mixed with gangue, by using the process on crude ore. The same remark applies to many of the other processes. To be sure, there has been some success in the Australian mills as well as in the United States in the treatment of mixed galena-sphalerite concentrates from flotation machines on concentrating tables. As an example, the Timber Butte mill is treating the flotation concentrate of a zinc ore containing some lead on James tables, removing the lead, and obtaining a zinc concentrate carrying 53% Zn, 1.5% Pb, and 4% insoluble. However, this method has not always met with the best results, and where the proportions of lead and zinc in ordinary complex sulphide concentrates are about equal it is quite hard to get two products that are sufficiently pure. Where it can be done, it is certainly more desirable than the more complex fractional roasting and preferential flotation processes of Horwood, Wentworth, and Ramage.

LYSTER. This is another process that has received consideration by the Zinc Corporation for the year or two preceding the European war. Lyster's process is carried on in neutral or alkaline solutions (never acid) of the sulphates, chlorides, or nitrates of calcium, magnesium, sodium, potassium, or of their mixtures, or solutions of manganese, zinc, iron, acid sodium, or sodium-potassium sulphates. Using eucalyptus oil or a similar frothing agent, the agitation of the pulp takes place in centrifugal pumps, throttled to give further agitation, and discharging into spitzkasten with constricted tops. It is said that a galena froth can be collected carrying 55 to 60% lead and that by sending the tailing to a second machine with further addition of oil, the sphalerite can be floated.

It will be noticed that this, with the possible exception of Wentworth's second patent, is one of the first proposals to give a true 'preferential' flotation to a mixture of sulphides, as the roasting methods above mentioned involve an actual conversion of some of the minerals, so that sulphide surfaces are no longer presented to the oils and air bubbles in the flotation operation. Lyster's process, however, involves the actual flotation of one mineral in preference to another, unless the chemicals used are chemically altering certain of the sulphides so that they cannot float. Anyone who has worked with mixtures of sulphides has doubtless noticed that greater care is necessary in the flotation of zinc sulphide than in floating galena; in fact, galena is one of the most easily floated minerals outside of molybdenite, and zinc sulphide is considerably more difficult to float. The fact that a froth running so high in lead as the Lyster process is reported to give would also tend to make one suspicious that rather poor flotation conditions are maintained, so that only the most easily floated material (galena), and only the purest of that, is coming up in the first product. This takes place even in the presence of considerable oil, whenever flotation conditions are poor on almost any type of machine, and while the grade of froth that is obtained is high, the extraction is poor on account of the fact that only the best mineral is floating. It is possible that some such combination of results as this has caused the process not to be considered unfavorably.

NUTTER AND LAVERS. Perhaps the most important disclosure of a process for preferential flotation of minerals is contained in the patent specifications taken out by E. H. Nutter and H. Lavers, U. S. Patent No. 1,067,485 of 1913. This patent was assigned to the Minerals Separation Co., as the patentees are engineers in the employ of that company. The wording of the patent shows more actual contact with flotation work on the part of the patentees than perhaps any other single patent that has been granted. They have observed that while controlling conditions in a flotation plant, the vary-

†T. J. Hoover, 'Concentrating Ores by Flotation,' *Eng. & Min. World*, July 18, 1914, p. 96; *Eng. & Min. Jour.* (1914) 97, p. 1208; *Mining & Scientific Press*, April 18, 1914, p. 657; *Metal. & Chem. Eng.* (1914), No. 12, p. 350 and 592.

ing of certain of these conditions has been accompanied by changes in the character of the froth coming off their machines, the metals coming off in various ratios to each other at different times, and for definite causes. Thus there is considerable difference in the sizes of the different minerals separated under various conditions. It is no uncommon experience while developing the machinery of a flotation mill to float all of the fine part of the gangue as well as the sulphide minerals. In like manner, the more easily flotative minerals are liable to come off in the first froth that issues from a machine accompanied by the more finely divided portions of the less easily flotative minerals. "This tendency is dependent upon several factors, such as the amount and character of the agitation and aeration, or of each singly, the chemical constitution of the solution employed as mill-water, the degree of dilution, the temperature and the amount and nature of the different frothing agents." "The word aeration is used in this specification to mean the supplying of air or other gas or gases." By sufficiently controlling all of these factors it is possible to obtain effective separation of galena and sphalerite as well as other sulphides and metals. By taking the various froths obtained by subjecting the pulp to varying conditions, and classifying on apparatus such as concentrating tables it is often possible to get good separation of the minerals contained.

One example cited is that of an ore containing sulphides of lead, copper, and zinc. From this can be obtained a froth containing most of the chalcopyrite, and not much of the galena or the sphalerite, by the use of cresylic acid (cresol) without the addition of mineral acid to the pulp. This froth can be re-treated under varying conditions to purify it. To the mill-pulp that has been depleted of its copper can be added sulphuric acid as well as the frothing agent, to obtain the major portion of the lead, and, finally, by the addition of such an oil as oleic acid, it is possible to float all of the zinc mineral, as well as any coarse particles of chalcopyrite and galena. The re-treatment of these froths by further flotation, or on tables, makes it possible to get good products of the grade demanded by smelters.

When using an ore containing only copper and zinc sulphides they state that with the use of cresylic acid or eucalyptus oil, without the addition of any mineral acid, it is possible to get a froth containing a proportion of the copper minerals, some fine zinc, and some still finer gangue. They also state that if the remaining pulp is heated and treated with a small amount of sulphuric acid, the froth obtained will contain an additional amount of more coarse zinc and copper minerals and that the zinc minerals are finer than the copper minerals. If oleic acid is added to clean the tailing, the froth obtained will carry much gangue, but most of the sphalerite and chalcopyrite are very coarse-grained. The treatment of these froths on vanning machines or tables gives the desired products.

Consciously or unconsciously, a number of operators have applied methods more or less like those claimed in this patent. By restricting the amount of oil used, it seems to be possible to float galena in the presence of sphalerite, though the lead product obtained always carries a good deal of zinc, and it is impossible to get all of the lead out before the sphalerite is floated by the addition of further oil. This is practically an application of Lyster's process, except that pure water is used instead of the solutions recommended by him. However, there can be no doubt that the addition of certain substances to the mill water does help in this type of flotation. In another plant where an ore containing pyrite and chalcopyrite is being treated, the first froth contains most of the chalcopyrite in a finely divided form, while only a small amount of the pyrite, in large pieces, comes to the surface. The property of chalcopyrite to disintegrate into very fine flakes on crushing has bothered mill-men in the old days when the production of slime was kept down to a minimum. Now it seems to be an advantage. These two instances of "controlling flotation" conditions are somewhat different from the ones implied in the Nutter and Lavers patent, and it is doubtful if it could be held to cover these cases, at least more than in part. However, too much attention cannot be given to their patent, as it discloses the methods by which preferential flotation will be first developed successfully, as far as I am able to see.

Greenway and Lowry. A further development of the idea of using a solution of some chemical that will permit true preferential flotation of one mineral in the presence of another flotative mineral is contained in the patent of H. H. Greenway and A. H. P. Lowry, No. 1,102,738 of 1914. They discovered that "if a salt of chromium (such as sodium bichromate or potassium bichromate) is introduced in solution into the circuit liquors, or if the material to be treated is subjected to the action of such chromium salt solution by digestion or otherwise, that the sulphides are affected in such a way as to leave certain of them amenable to flotation, whereby products are obtained relatively high in certain sulphides on the one hand, and relatively high in the other sulphides on the other."

Three examples are cited: (1) A molybdenum ore containing 15% molybdenite and 25% iron pyrite was crushed to pass 100-mesh screen and treated in a froth-flotation apparatus with four times its weight of water containing 0.25% sodium bichromate, and heated to 120° F. One pound of eucalyptus oil per ton of slime was used and the flotation product consisted of 93% MoS_2 and 4.9% iron pyrite. Attention should be called to the fact that this example does not tell as much as it would seem to say, for the reason that molybdenite is one of the most easily floated minerals. I believe that work of a character more nearly comparable with this result could be obtained without the use of chromates.

The second example cited is of a copper ore containing 6.5% copper and 35% iron. This, likewise, was crushed to pass a 100-mesh screen and digested in a hot solution of 1% sodium chromate for about 30 minutes, the liquor decanted and the mineral treated in a flotation machine with one pound of eucalyptus oil per ton of dry slime. The flotation product contained 19% copper and 30.2%

iron, while the residue contained 0.7% copper and 36.2% iron. When we remember the case cited above of separating the chalcopyrite from the pyrite by virtue of the fact that fine grinding takes the copper down to a much finer product than it does the iron, we are led to wonder if this process is really necessary for this kind of ore. It may be that a better grade of product and a higher extraction can be obtained by this method than without the addition of bichromate, but otherwise it is doubtless possible in most cases to do the same work with proper control of ordinary conditions.

Their third example is of a lead-zinc slime containing 18.6% lead and 32.3% zinc, which was digested for 30 minutes in warm solution of 1% sodium bichromate. The solution was decanted and the material subjected to froth-flotation with one pound of eucalyptus oil per ton of slime. The flotation product contained 47.2% zinc and 6% lead, while the residue contained 31.6% lead and 16.3% zinc. The solution was heated to 120°C. These are interesting figures, but there is too much zinc in the lead concentrate. Here again I feel that the work is not much better than it would be without the aid of bichromates. By taking advantage of the fact that galena floats more easily than blende, it is possible to get a galena froth from an ore that will contain 54% lead and 15% zinc, while the blende-froth that follows will contain 37% zinc and 20% lead. This type of work errs in the other direction, that is, in having too much lead in the zinc product, but the point is that the addition of bichromates does not make a separation which is any more advantageous than does preferential flotation by other methods. However, the fact that the galena can be deadened by treatment with a weak solution of sodium bichromate is most interesting in that it shows that a true preferential flotation is possible. It is assumed that the action of the bichromate solution must be that of oxidation of the surfaces of the galena to insoluble sulphate while such an action on the sphalerite could not be possible, as the zinc sulphate would dissolve. The treatment of the high lead-zinc product of this last mentioned preferential flotation product by the bichromate process might be a useful method of cleaning this kind of concentrate. It is probable that successful preferential flotation will develop along such lines, though bichromates are not the only chemical that will be used. While the results obtained by this process have been shown to be capable of duplication otherwise than by the use of bichromates, this fact of the peculiar action of weak bichromate solutions is thankfully accepted and further work is urged to discover if it can have a field of application peculiarly its own.

Bradford. Another process along these lines is that revealed in British Patent No. 21,104 of 1913, by L. Bradford of Broken Hill. He claims the use of a solution that will wet one of the sulphides which it is desired to separate from the other preferentially without chemically altering the same. A medium which will wet galena particles and allow sphalerite and pyrite to float unaffected is a solution of one or more of the alkaline chlorides, slightly acidulated and heated to about 120 to 160°F. On account of its low cost a solution of sodium chloride is used, and Bradford states that there are no definite requirements as to how concentrated the solution shall be, but suggests a 10% NaCl solution as about the right strength to use.

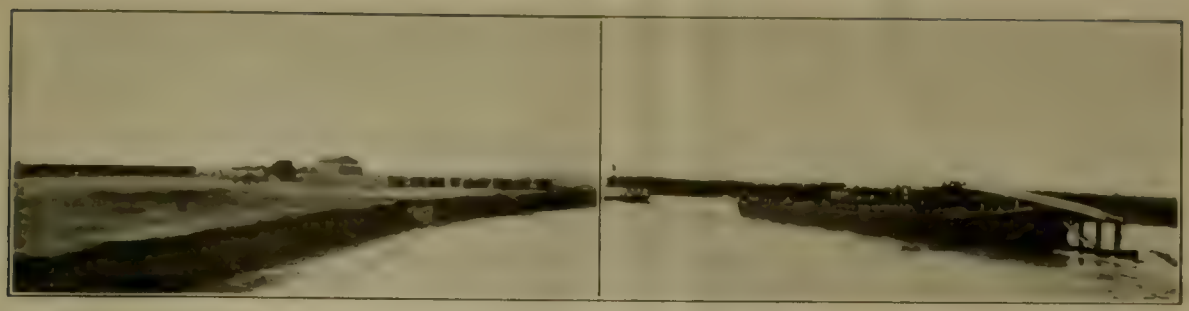
The acidity should be about 0.1 to 0.2%, for a higher amount than 1% will cause the flotation of galena on account of the formation of hydrogen sulphide bubbles on its surface. He states that if the process is applied directly to crude ores the use of a frothing agent is not necessary, although it will cause no harm if added. Any well-known apparatus can be used for the flotation.

The invention may be applied either to the crude ore or to the mixed flotation concentrate from the ordinary method of flotation. Where the plant is used on crude ore the tailings from the flotation of the sphalerite and the pyrite are agitated again in pure water with a frothing agent in order to float the galena. On account of this requirement it is thought better to make a mixed concentrate first by ordinary flotation and then separate preferentially as above described. This latter method, however, makes a higher-grade zinc concentrate.

When treating ordinary mixed flotation concentrate, it is best to remove the oil on the surfaces by the use of an alkaline or other alkaline carbonate solution, or by either. Further, finely ground material is liable to agglomerate too quickly, so that some of the galena will be entrained mechanically with the agglomerated sphalerite and decrease its value. In these cases it is desirable to add an agent that will retard flotation. Substances suitable for this purpose are sulphites or thiosulphites of alkalies or sulphur dioxide, but they must be used sparingly and with care or they will entirely spoil all flotation. He thought so much of this latter step that he later incorporated it in a separate patent (Brit. Pat. No. 19,844 of 1914). No further description of this patent is necessary.

There are many other proposed methods in the patent literature of England, Germany, France, and the United States, concerning which I am not fully informed, but it is believed that most of the important ones have been reviewed. Many interesting facts are disclosed, such as the fact that galena and sphalerite will not float in a solution containing zinc chloride of the right concentration and acidified by hydrochloric acid (German patent, No. 282,234). Aniline compounds are said to allow flotation of galena in preference to sphalerite, etc.

It will doubtless be noticed that little mention is made of the kinds of machinery used in the above methods of preferential flotation and there will doubtless be some question as to whether or not these principles can be applied equally well in the mechanically-agitated and in the pneumatic-agitation machines. Most of the above processes, where not specifically stated, have been worked out with the aid of mechanically-agitated machines, but it is possible to apply most of them to the pneumatically-agitated machines, such as the Callow or the Towne. Such machines, due to the economy of power in making froth, and the ease of control of flotation conditions, will doubtless materially assist in the development of preferential flotation.



EBMAK, THE RAILWAY TERMINAL. BARGE ON THE IRTYSH.

The Altai Region, Siberia

By H. W. TURNER

INTRODUCTORY. The following description of the Altai is based on observations made and data obtained in 1914 for the Russian Mining Corporation of London, to whose courtesy I am indebted for permission to publish them. The writings of Bernhard von Cotta, J. Hergenreder, and others have been freely utilized. The statistics of past production are mostly taken from the official records at Barnaul by courtesy of E. D. McDermott.

Southwestern Siberia, where traversed by the Trans-Siberian railway between Cheliabinsk in the Urals and Krasnoyarsk on the Yenesei river, is a vast plain, or steppe, and nearly level. This area as a whole is devoid of metalliferous deposits. It may at one time have been covered by a sheet of water, as will be noted later in this description. At many places the steppe is dotted with lakes, both salt and fresh; it extends far north of the railway; it is bordered on the west by the Ural mountains, while on the southwest it merges into the Kirghese steppe and south is limited by the Altai and other ranges.

The Russian side of the Altai mountains comprises that portion of the Siberian-Mongolian frontier ranges that are drained by the Ob river and its branches, the Irtysh and Tom. In the southern part of the Russian Altai, there are high peaks covered with snow even in the summer, one of which, Mt. Beluka, is credited with an elevation of 12,790 ft. above sea-level. While in general the region shows no evidence of glaciation, it is quite probable that local glaciers at one time existed in the highest part of the Altai, as suggested not only by the existence of summer snow at the present time, but also by the topography as seen in photographs. The known mining district of the Altai lies entirely in the foot-hill region and chiefly on the western side of the Russian Altai to the east of the Irtysh river.

THE GREAT STEPPE. Extending west and north of the Altai is the great Siberian steppe, already mentioned, a portion of which, bordering on the mining region, is shown on the accompanying geological map (Fig. 1). This map shows the limit of the metalliferous formations to the northwest of Zmeinogorsk and a steppe topography characterized by streams and strings of lakes lying in NW-SE troughs. At first glance it might seem that these troughs were due to NW-SE flexures of the flat-lying sediments or to faults. Von Cotta considers these troughs due to rows of sand dunes formed on the shore of a former shallow sea, the dunes lying parallel with the ancient shore-lines. This, in a measure, is confirmed by the geological map of von Petz (Fig. 1), which indicates that sand dunes border the troughs. Most of the lakes are salt or bitter, and there exists in this district extensive deposits of salt, which supply the inhabitants of the Irtysh basin. This saline portion of the plain is said to be called the "hungry" steppe. Some of the streams flow north-east into the Ob and others south-west into the Irtysh. The peculiar topography just described extends at least 130 miles north-west of the Alei river.

The Great Steppe, according to von Cotta and others, was a land surface from after the Carboniferous until Post-Pliocene time. During this dry period, the older rocks were much decomposed and disintegrated by the sun, wind, rain, and frost, forming a great mantle of loose material —the dust from which was no doubt shifted about by the wind, causing loess deposits. In Post-Pliocene time the region was submerged and these loose materials were spread over the basin by water action, forming the horizontally bedded deposits as seen today and loess (fine dust-like material showing little evidence of bedding), which may have been laid down in periods of low water by wind action. Von Cotta thought that the basin was covered by an arm of the sea but Adiassewich† notes that Dr. Martens of Berlin determined six kinds of fresh-water shells of species still living in Siberia from a collection contributed by the Post-Pliocene beds of the Irtysh basin.

Thomas Belt regarded the sediments of the Great Steppe as being formed in an enormous lake, which was caused by an ice-sheet damming back the north-flowing

†Trans. Inst. Min. and Met., London, Vol. XVII, p. 516.

rivers. However, neither von Cotta nor more recently C. W. Purington and G. Frederick Wright, have seen any evidence of glacial action in this central and southern Siberian region. Glaciers, if they existed, were probably local and grouped about high peaks like those of the Altai near the Mongolian border.

Finally De Launay describes horizontally bedded deposits of Tertiary age underlying the Great Steppe, so that the details of its origin must still be considered an open question, and for the purposes of this paper, it is only necessary to look upon it as a vast plain barren of valuable deposits, unless there be lignite beds in the Tertiary strata. On the other hand, its value from an agricultural point of view is enormous, as outside limited areas the soil is very fertile and affords pasturage to many hundreds of thousands of cattle, horses, and sheep. Settlement is being rapidly effected by Russian immigrants, who are given every aid to establish themselves by the Imperial government. Already it is a great butter-producing region, supplying Russia, England, and Denmark.

The Kirghese Steppe. Far to the south of the Trans-Siberian railway and to the west of the Irtysh river chiefly in the Akmolinsk and Semipalatinsk provinces, is the Kirghese steppe, in which are numerous groups of hills composed of rocks older than the Tertiary. These older rocks, following the Russian geologists, are of Carboniferous, Devonian, and Silurian sediments with intrusions of granite, diabase, porphyry, etc. The Carboniferous beds contain valuable coal seams and in the series generally are numerous deposits of gold, copper, lead, and zinc ores. Two of the copper deposits, the Spassky and the Atbasar, have been opened up by English companies. The Spassky, which also controls the Atbasar, is an example of the successful operation of a base-metal deposit far removed from the railway (500 miles from Petropavlovsk) with only horse and camel transport for the movement of supplies and the copper product. Such an operation would hardly be possible were it not for the existence of coal beds in the vicinity to supply the smelter with fuel. In the Semipalatinsk province, the Ekibastus coal beds are being developed by the Irtysh Corporation of London.

The Altai Mountains comprise that portion of the Siberian-Mongolian frontier ranges that is drained by the Ob river and its branches the Irtysh and Tom. These mountains lie in both Russian and Chinese territory. The known mining district lies entirely in the foot-hill region and chiefly on the western side of the Russian Altai, east of the Irtysh river.

Notwithstanding the great distance from the sea (Semipalatinsk is about 1200 miles south of the head of the gulf of Ob and the distance following the windings of the river is much greater), the elevation above sea-level as given by the Government engineers is not great. Semipalatinsk is only 686 ft., Ust-Kamenogorsk, 804 ft., Ust-bukhtarminsk, 1309 ft., and Lake Zaisan, 1356 ft. above the level of the Baltic sea. The mines are mostly among the hills, which seldom attain an elevation of above 3000 ft., the highest elevation in the immediate neighborhood of important mines being those to the east of the Ridder group, where the summits reach to about 6000 ft. The mines themselves however are generally on the lower slopes at elevations of between 1000 and 2000 ft.

Prehistoric Mining. When the Russians in the middle of the 18th century first undertook the exploitation of the metalliferous deposits of the Altai, they found at many places evidences of ancient mining. Thus Pallas, who traveled through the district late in the 18th century, writes: "The traces of former mining, which were observed at Zmeinogorsk are much too notable to be passed over in silence. The surface ores as well as those in the deeper part of the hill (Schlangenberg) were known to the ancient miners whose industry in working the Altai deposits was so remarkable. They extracted not only the rich surface and soft oxidized ores but also sank shafts to the depth of five or more fathoms. In the hard ores they generally failed to penetrate far, from lack of means and tools. Yet one can see in one of their open-cuts a caved excavation where they appear to have attempted to extract the hard spathic ore, and really sank in the hard rock a funnel-shaped pit. In recent operations tools used by these ancient miners have been found under broken ore. A pick and other mining implements, made of copper, were uncovered at a depth of 10 fathoms. From this it appears that iron was unknown to them; as is also indicated by the copper daggers, arrow-points, etc., found in their oldest graves in the mountains and on the steppes. Instead of hammers, they used hard rounded oblong stones in which a groove was cut, probably for fastening a strap with which the stones were held. At any rate, such stones are found in their graves. Moreover, a few years ago, under ore in a caved shaft, an entire skeleton, half mineralized, was found and by it a leathern sack full of rich ore."

Evidence was still extant, at the time of the visit of Pallas, of the former washing of the Zmeinogorsk ores for gold, in heaps of tailing situated along the neighboring stream.

These ancient workings, evidence of which was found at many of the important mines, are generally ascribed to a race called the Chuds (meaning, in Russian, queer or odd people) and Pallas was of the opinion that this race was not of Mongolian or Tartar origin, since those tribes in ancient times, and later, knew well how to smelt iron, but did not understand the winning and smelting of either copper or the precious metals. Convincing evidence of the existence of a former race is furnished by the graves or tumuli that are scattered all over the Irtysh basin but are said to be best developed along the Yenesei. Repeated investigation has shown these mounds to be burial places of an ancient race now entirely gone. The mounds contain not only skeletons but ornaments and implements made of copper and gold, as well as stone images.

Besides Russians, the present inhabitants of the Irtysh basin are chiefly the Kirghese, who are mostly a nomadic and pastoral people with herds of cattle and horses and flocks of sheep. It is an interesting fact that hunting

with falcons is still practised by them. They are an ignorant but useful people, good horsemen and drivers; and they make good servants and are in evidence as cabdrivers in all the large towns of the Irtysh basin. There are also all throughout the region, from Lake Zaisan north, numerous Cossack reservations, made in former years when there were frequent incursions of hostile tribes from Mongolia. My information is to the effect that the Cossacks own the reservation lands in perpetuity, it being required in return that they give their services for military duty immediately on being called and they also have charge of post-stations on their reservations. They are brought up with the idea of becoming cavalrymen, which explains why they are so independent and reckless in their demeanor. Many from this district are now in the great European conflict. The Cossacks not only own the reservation lands in perpetuity but also the mineral deposits that they may contain.

FIG. 1. GEOLOGICAL MAP OF COUNTRY NORTHWEST OF THE ALTAI.

THE RUSSIAN ALTAI. We return now to the Russian Altai, which lies chiefly in the Tomsk province. No reliable information is at hand regarding the geological formations and ore deposits, if there be any, of the higher Altai mountains. The mining region lies in the foothills. Here the formations, following the Russian geologists, comprise chiefly Carboniferous and Devonian sediments, mostly tilted and more or less metamorphosed, with intrusions and flows of igneous rocks: granite, diabase, porphyry, and numerous greenstone dikes. The Carboniferous strata contain beds of coal as in the Koosnetsk basin and at Kalchugina to the north and east of Barnaul, while the Devonian strata, chiefly graywacke, clay slate with lenses of limestone and beds of tuff, contain many of the important lead-zinc deposits. In the porphyries are many copper deposits, a few of which have been quite productive. There are also important deposits of copper, lead, and zinc in schist of igneous origin. In general the granitic areas are barren of metalliferous deposits. The general distribution of these formations is much the same over the entire mining district, but the geology is complex, as may be seen from the geological map of the neighborhood of Zmeinogorsk. Nevertheless a study of the district as a whole shows

two important NW-SE lines of mineralization. The eastern belt, although broken and displaced by granitic intrusions, is the more important and in it are found the Zmeinogorsk, the Ridder, and the Zyrianovsk groups of mines; from these has come the chief production of lead and silver, the zinc not having been recovered. Separating the eastern group from the western there is a broken belt of granite. The western belt lies along the lower foot-hills and has to date been most productive in copper, although there is some lead and zinc in nearly all of the deposits.

From the data at hand it would appear that the first serious mining in the Altai was undertaken about the middle of the 18th century under Demidoff with serf or convict labor. Records of production as early as 1747 are to be found at Barnaul. Later the best mining areas were taken over by the Czar as his private domain, and these areas have since been administered by the Cabinet, the name given to the group of officials having charge of the private Imperial lands. The headquarters of the Cabinet are at Petrograd and the local headquarters for the western Altai district are at Barnaul, whither one must go to get any reliable information as to past operaitons and production. Incomplete statistics from the records at Barnaul show the Barnaul district to have produced 45,550,000 ounces of silver and 30,000 long tons of copper. There was also a notable production of lead, probably in excess of 500,000 tons. The above statistics do not include the important output of the Zyrianovsk mine nor of the Salair, and of many prospects, the data for which are not at hand. The gold yield is not given. By far the larger part of the silver, lead, and copper was produced prior to 1866, about which time the production began to decline.

It may have been for this reason that in 1868 Bernhard von Cotta of the Freiberg Mining Academy was commissioned by the Czar to visit the Altai, where he spent about two months, returning home with extensive collections. Von Cotta made the following observations and recommendations:

1. To search for new orebodies and exploit the existing mines more thoroughly.

2. Since the forests had disappeared from the vicinity of the mines and smelters, to re-forest the devastated areas.

3. On account of the lack of fuel, to search in the Altai for beds of commercial coal or to connect the known coal basin of Koosnetsk with the smelters by a railroad.

4. To improve the method of transport of ores; for then as now, the ore was hauled in open carts and sleds of rude construction and small size, resulting in considerable losses as long distances were frequently traveled, up to 150 miles or more.

5. To endeavor to recover the zinc. Since many of the Altai ore deposits contain not only zinc-blende but also *galmei* (an old name for oxidized zinc ores) in large quantity, which are not used, so he pressed the question whether this metal content could not be used. With the winning of the zinc, one must naturally go further and manufacture zinc products in order to make the zinc useful and desirable to the people. Von Cotta suggests the making of sheet zinc for roofing houses and churches, zinc pipes for water-conveyance and zinc castings in the form of ornaments as well as brass for buckles and harness ornaments, which in this region of a plenitude of horses should find a ready market.

It would appear that only the first of these recommendations was heeded. There was vigorous prospecting after the date of von Cotta's visit, but no re-foresting was done, no coal mines were opened up, no improvements in transportation were made, the production and beneficiation of zinc apparently was not attempted, and certainly not accomplished. So far as known, von Cotta was the first to call attention to the importance of the Altai as a field for zinc production and it remained for English mining companies 45 years later to begin seriously the mining and beneficiation of zinc ore. The smelter of the Irtysh Corporation is now being built, and spelter or zinc products will no doubt be on the market in 1917, while the Russian Mining Corporation, which began operations later, will also be a producer in the near future. This delay in the production of zinc was due to the lack of knowledge of zinc smelting as well as to the difficulty of separating the zinc from the other constituents by the then known methods of concentration. It is evident from the report of von Cotta that the existence of large amounts of zinc in the Zyrianovsk mine was well known, but the great size and high zinc-content of the Ridder deposit remained to be proved by the Russo-Asiatic Corporation. As a matter of fact, zinc is the most abundant metallic constitiuent of the Ridder ore (14.7% on average), moreover its assay-value at Russian prices equals 42% of the total gross value of the average Ridder ore. The same is true of the ore of the Zyrianovsk mine, where zinc is present in somewhat greater quantity. That we have in the western Altai a new and important zinc-mining district is further shown in the finding of zinc, often in commercial quantity, in the old workings and on the dumps of nearly all the prospects and mines that were worked for copper and lead by the Russians. Mixed sulphide ores are thus the rule in this portion of the Altai.

Recent Operations. Early in the present century, a concession was granted to Prince Thurn and Taxis of Vienna. This comprised the three most prolific districts of the western Altai, the Zmeinogorsk, the Ridder, and the Zyrianovsk. (See Fig. 2). The Ridder district later passed to the Russo-Asiatic Corporation and the Zmeinogorsk and Zyrianovsk to the Russian Mining Corporation. Both of these companies have developed large and valuable bodies of complex ores by drilling.

A general geological map of the Altai will require first a topographic base and then some years of careful fieldwork. Such work is ordinarily undertaken by the general government. A survey has already been initiated and many of the hills of the mining region are surmounted by triangulation stations, indicating the considerable triangulation work that has been done. Maps of the entire Irtysh basin have been issued, but these will require revision before accurate geological maps can be con-

structed. Geological work has also been started and G. von Petz, a Russian geologist, constructed a geological map of the quadrangle in which Zmeinogorsk is situated. From a copy of this map, scale, one inch to 10 versts, as yet unpublished, I prepared the map shown in Fig. 1. Such maps would be valuable for general reconnaissance, but what is needed for mining purposes are maps on a more detailed scale of the known mining belts, which comprise but a portion of the mining region, as the granitic areas appear to be devoid of valuable mineral deposits. But little work has as yet been done and that chiefly by the English companies. During the year 1914, the chief work of my own party was necessarily the investigation and sampling of the old mines, the study of the mine-plans and the collection of statistics of past production, for the purpose of determining the best

THE FOOT-HILLS.

THE ZMEINOGORSK MILL.

places for drilling under the old workings and elsewhere, so that only the formations immediately adjacent to the known ore deposits were examined.

A considerable number of the silver-lead-zinc mines are found in bedded and schistose rocks. Frequently on one wall or other of the deposits there are lenses of a fine grained flinty rock, locally called 'hornstone.' This hornstone is pretty certainly a silicified limestone, and von Cotta records the finding of impressions of fossil shells in this flinty rock, which often contains gold and silver. The silicification of this rock presumably occurred at the time of the formation of the ore deposits themselves, although evidence of subsequent mineralization is seen in some of the mines. In places there are clear indications of fissuring and faulting of the beds preceding the deposition of the sulphides, but the great mass of the ores are replacement deposits and are without doubt of epigenetic origin. At nearly all of the mines there are greenstones dikes, which sometimes carry chalcopyrite. Whether or not this chalcopyrite is of magmatic origin or was introduced later by solutions has not been determined. Accepting old analyses as correct, these dikes have in some cases approximately the chemical composition of diabase. These greenstone dikes cut all the other formations, both sedimentary and igneous, and even the ore deposits themselves in some cases. They represent presumably the last indication of igneous activity in this mining region, there being no evidence of Tertiary volcanic action.

In the Zmeinogorsk mineral belt, there are zones of chlorite-schist underlying the Devonian slate and graywacke. This schist is presumed to be the product of metamorphism of clay slate by the magma of the adjoining intrusive granite.

In the Zyrianovsk concession, there are extensive belts of schistose quartz-porphyry and of greenstone-schist. These probably represent surface flows of lava of Devonian time folded and compressed within the Devonian sediments. In the western and central part of Zmeinogorsk mineral belt, however, the porphyries show no such compression and metamorphism, and are plainly intrusive in the Devonian sediments.

THE ZMEINOGORSK BELT. The main product of this belt has been silver and lead, but the small mines in igneous schist in the east portion of the belt, like the Lazursky, produced chiefly copper.

The Zmeinogorsk lode and the enclosing formations, taken as a whole, dip northerly at about 60° with numerous irregularities due to porphyry intrusions and faulting. The formations in brief are as follows, beginning at the south with the foot-wall formations: Chlorite-schist, clay-slate, hornstone, then the barite lead-silver lode, with clay-slate penetrated extensively by porphyry for the hanging wall. The hornstone lens thus forms the direct foot-wall of the baritic lode, which was the source of the chief ore-supply of former times. Cutting all of these formations, including the baritic vein, there are greenstone dikes. The hornstone forms a huge mass, presumably wedging out in depth; and for some years it has been mined for gold and silver, the ore being treated in a stamp-mill and the tailing cyanided. This lens of hornstone probably contains 7,000,000 tons of rock, all of which contains some gold and silver, but the amount of commercial ore is as yet undetermined. For some years the chief supply of gold ore has been taken from the surface along two greenstone dikes, as the ore is here of higher grade and if the old records are correct the main ore-shoot of the baritic vein pitched with one of these dikes, suggesting that this intrusion was followed by a renewed circulation of heated waters causing a concentration of valuable mineral along the dikes or an additional deposition of the precious metals, for the baritic vein itself was certainly formed before the intrusion of these dikes. The Zmeinogorsk mine is credited with a production of 30,000,000 oz. silver and a large tonnage

of lead up to 1855. The gold production is not given in the records available.

The geological formations at the Karamishevsk, Petrovsk, and other mines of the western part of the Zmeinogorsk belt do not differ greatly from those at Zmeinogorsk.

The Ridder Mine. Following the published description of this deposit by H. H. Knox, the Ridder lead-zinc deposit dips steeply in the old upper workings, flattening in depth as shown by the bore-holes. The hanging wall consists of clay-slate and ancient tuffs. At the date of his report, Mr. Knox estimated that a total of 2,448,000 long tons of ore had been developed containing gold 0.54 oz., silver 4.46 oz., copper 0.7%, lead 8.21%, and zinc 14.7%. Since that date additional drilling is reported to have largely increased the tonnage of the complex ore, and sampling in the old workings has revealed 100,000 tons of oxidized gold ore containing 18 dwt. per ton. On this concession the old Sokolni and Krukovsky also look promising for development.

The Ridder mine is under a 72-year lease to the Irtysh Corporation, a subsidiary of the Russo-Asiatic. The Ridder complex ore will be separated into two products at the mine by water-concentration, yielding a zinc-copper and a lead product. The concentrates will be shipped by railway to Ust-Kamenogorsk on the Irtysh; thence by barges to Ermak; thence by railway to Ekibastus, about 75 miles west of the Irtysh river, where the smelters are now being erected. It is expected that the first units of the zinc-smelting plant will be in operation in 1916.

The Zyrianovsk Mine of the Russian Mining Corporation lies about 50 miles south-east of the Ridder, to which it is in many respects similar. The croppings occur on a low hill at the west end of the lode. This hill consists chiefly of clay-slate and other sedimentary material with nearly vertical dip, with layers or intrusions of quartz-porphyry and numerous greenstone dikes with some quartz veins. The central and eastern parts of the lode are buried under alluvium. The strike of the lode is approximately east-west. Bore-holes from the north side show that the country on the hanging-wall side is composed of two layers of a fine grained micaceous silicious tuff with intervening bands of quartz-porphyry schist.

The ore deposits consist of a series of lenses of complex sulphides. Many of the lenses, as indicated on the old charts, fork upward, downward, and horizontally, and some are apparently otherwise irregular, while on the whole they conform in strike and dip with the enclosing schist. These lenses are grouped into two series or zones, which for the purposes of description may be called the north and south ore-zones. The two series unite at the west end of the mine and diverge going easterly on the strike and to some extent going down on the dip, the north zone dipping northerly at about 60° and the south zone southerly although irregular (see cross-section of deposit through the Staro-Vostochny and Severny shafts. See insert within Fig. 3). The south zone up to date has produced the most ore, but the north zone has been followed to a greater depth and been recently penetrated by two bores showing material extension of the previously known orebodies, one bore passing through 70 ft. of complex sulphide ore at a depth of about 120 ft. below the lowest level of the old mine or about 870 ft. vertically below the collar of the Severny shaft (see Fig. 3). There is also a zone of impregnation near the bottom of the bore. About 30,000 tons of ore is accumulated on the dump and according to the report of R. A. Varden made some years ago there are exposed in the mine about 133,000 tons of commercial ore. Repeated series of assays of the different exposures of ore indicate the following contents:

Ore on dump:	Ore, long tons.	Gold, Oz.	Silver, Oz.	Copper, %	Lead, %	Zinc, %
Sorted	10,700	0.65	15	2.5	13	23
Unsorted	19,400	0.3	8	2.0	10	18
Ore in mine.....	133,000	0.35	19	2.6	11	23
70 ft. of ore in bore No. 2....		0.023	8	1.9	10	18

Numerous other old mines on the Zyrianovsk concession merit attention; one of these, the Zavodinsky, produced lead ore high in silver with a limited amount of telluride ore. In this connection it is interesting to note that Fritzsche found the rare metal indium in the sphalerite of Zyrianovsk.

The Copper Belt of the Zmeinogorsk concession stretches along the western edge of the foot-hills of the Altai for a distance of 90 miles in a north-westerly direction, begining with the Belousovsk mine near the Irtysh river. The belt in addition to copper contains silver-lead and zinc ores. The records show that this belt has produced over 3,100,000 oz. silver, 7000 tons of lead, and 25,500 tons of copper. It thus forms an important line of mineralization.

While the various mines of the belt are nearly in a line, they do not occur in a definite lode or shear-zone like the Broken Hill lode in Australia or even the Mother Lode in California. The different mines are in different formations and no fissures or shear-zones continue even approximately from one to the other. The Belousovsk copper mine is in a belt of clay-slate and igneous schist: the Berezovsk lead mine is in clay-slate and igneous schist: the Titovsk copper-lead mine is in slate, quartzite, and graywacke; the Gerichovsk lead-silver prospect is in slate and limestone; the Nikolaevsk silver mine is in porphyry, so far as can be told from fragments on the old dumps; and the Chudak, Sugatovsk, Zolotushinsk, and Loktevsk copper mines are in porphyry and felsite.

The Kalbinsky Mountains. Between lake Zaisan, near the head of the Irtysh, and Ust-Kamenogorsk the Irtysh river has cut a rugged canyon through the south-western Altai foothills. The ragged ranges situated to the west of the Irtysh are known as the Kalbinsky mountains. According to J. Hergenreder, these mountains consist of Devonian and Carboniferous beds with intrusions of granite. The Carboniferous formation prevails and is composed of clay-slate, sandstone, limestone, and conglomerate. The sedimentary beds show evidence of contact-metamorphism near the granite, showing the granite to be intrusive. Gold placers were formerly worked in these mountains and more recently some gold-quartz mines, some of which are indicated on the map,

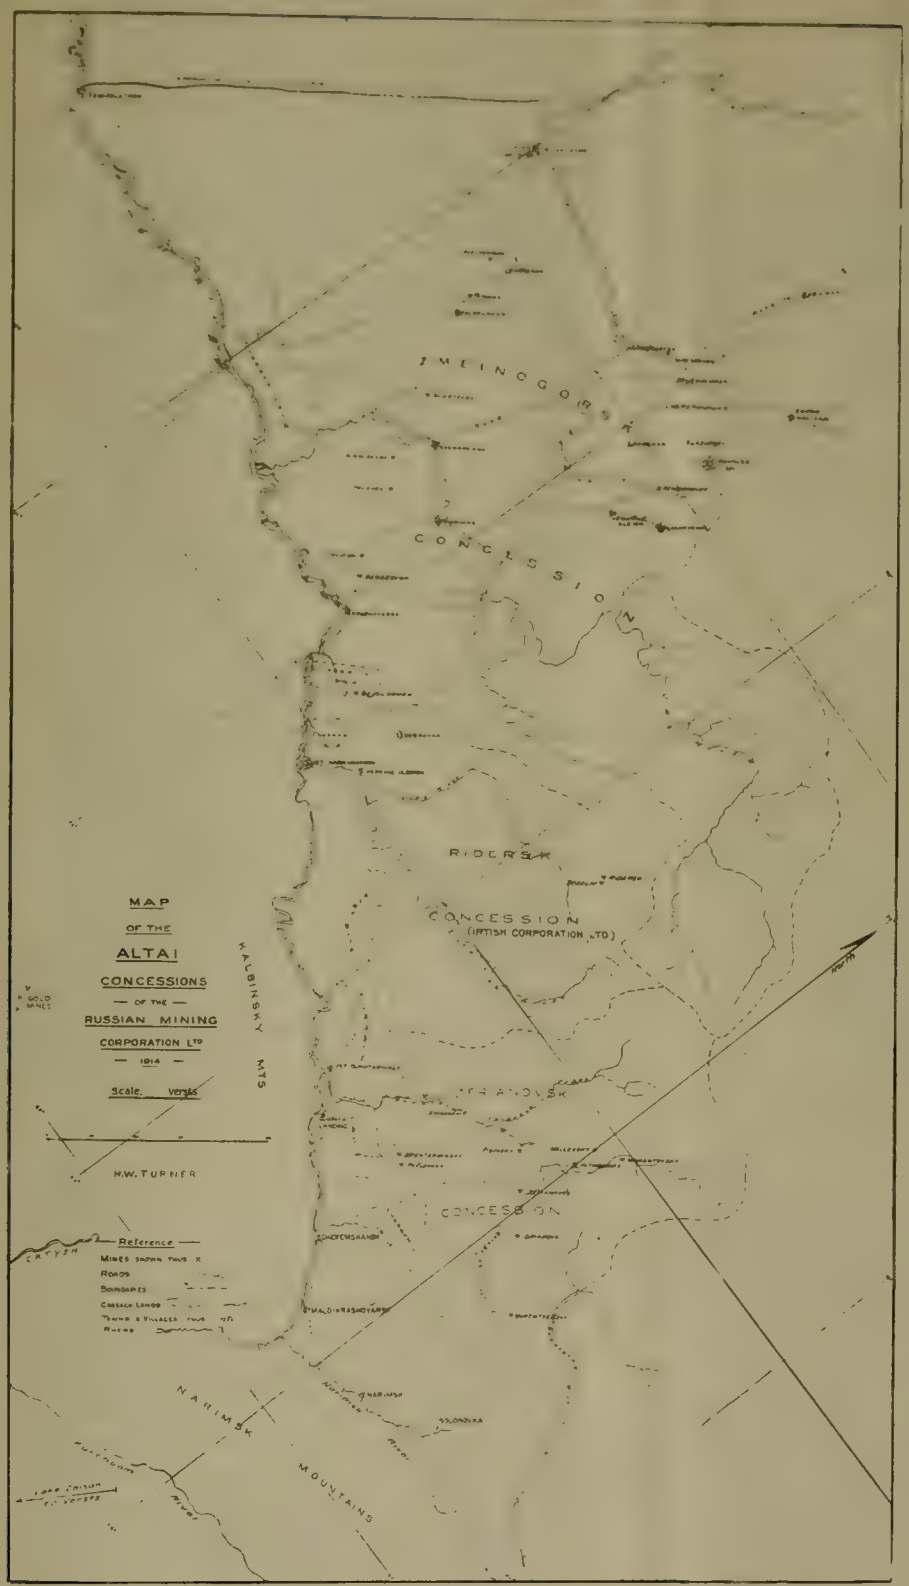


FIG. 2.

Fig. 2, have been opened up by the Russians with some success. There are also iron and manganese deposits in this district.

TRANSPORTATION. The western Altai is most easily reached by going to Omsk on the railway and there taking a comfortable Irtysh river-steamer to Semipalatinsk, Ust-Kamenogorsk, or other convenient point. The same steamer runs to Lake Zaisan, near the Mongolian frontier.

The Irtysh river is open for navigation, between Omsk and Ust-Kamenogorsk, from May to the middle of October. In the autumn the freezing of the smaller tributaries lessens the quantity of water in the main river and it is due to this rather than to the freezing of the Irtysh itself that navigation usually closes down in October. This, however, can be remedied by dredging at the shallow places. Both bucket and hydraulic dredges are now in use, although thus far only for deepening the water at landings. Navigation on the Irtysh should be practicable in most years until the middle of November when proper channels have been excavated.

The new 5-ft. gauge Government railway from Novo-Nikolaevsk to Semipalatinsk is now nearly finished and will presumably be open for traffic as soon as the bridge over the Ob river at Barnaul is completed. A railroad paralleling the Irtysh from Semipalatinsk to Omsk is also projected by the Government.

The private railway of the Irtysh Corporation from Ermak to Ekibastus is now available and the line from the Ridder mine

to Ust-Kamenogorsk will probably be finished in 1916.

At the present time most of the land transport is done on small four-wheeled carts in the summer and on sleds in the winter, at a cost of 10 kopecks (5 cents) per ton-mile, the price depending on the quantity of freight and the season of the year. Formerly much ore was transported 150 miles or more by this method.

Labor. Considerable portions of the mining region are under cultivation and Russian labor is cheap and plentiful, except during the planting and harvest season. The men now employed at the operating mines, both for surface and underground work, are chiefly Russians. There are lignitic deposits along the Irtysh and this coal is now being used by the Irtysh steamers. Near Lake Zaisan also lignite beds are said to abound.

The main coal-fields, however, lie to the north and east of Barnaul, of which the Koosnetsk basin and the mines at Kalchugina are the most important for mining purposes since they are near. These coal formations are said to be of Carboniferous age and to include fine coking and anthracite seams. A French company is opening up the Kalchugina mine, which will be connected with the Semipalatinsk and Novo-Nikolaevsk railroad.

Food-Supplies. Nearly all kinds of vegetables and

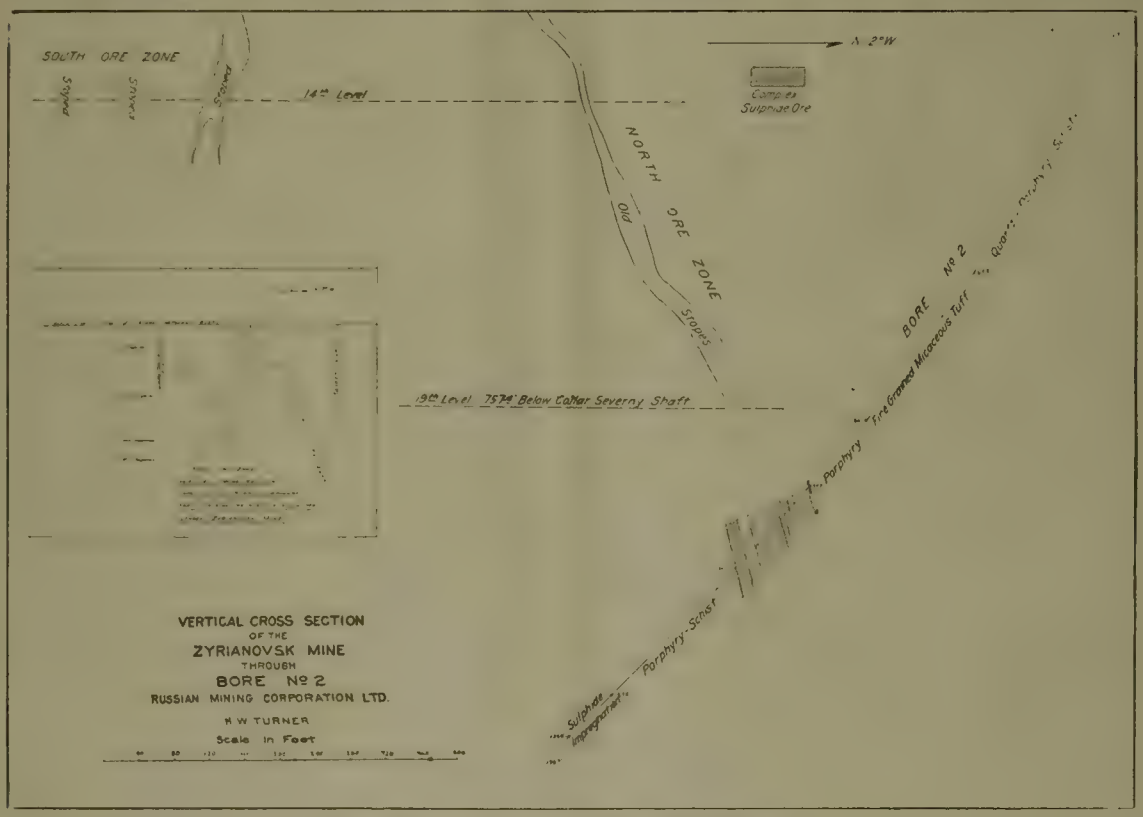

Fig. 3. Cross-section of the Zyrianovsk mine.

but when extensive underground operations are undertaken it will be found better, as at Kyshtim in the Urals, to use Tartars or other Russian or Siberian natives for this work. The average pay of a Russian miner at present is about one ruble (51.5 cents) per day.

Fuel Supply. The smelting of former years was done chiefly with charcoal; this, with the extravagant use of timber in underground works, for building houses and for domestic fuel, has decimated the forests that formerly covered the hills near the mines.

In those districts where wood-fuel is now too expensive the peasants use manure, which is cut into bricks and dried in the summer.

The fuel of the future will be coal and coke. The extensive deposits of Ekibastus are being opened up by the Irtysh Corporation not only with the object of supplying their own needs but for placing coke on the market.

some kinds of fruits are grown in the Irtysh basin. Cattle, sheep, and hogs being plentiful, fresh meat is cheap, as well as poultry, eggs, butter and milk. Fresh fish likewise is available. North-east of Pavlodar, there are large deposits of rock-salt. An increasing quantity of grain is grown and hay is cut to an enormous tonnage.

Mining Supplies and Machinery. While nearly all mining supplies and machinery must be imported, considerable stocks of iron and steel are kept at Ust-Kamenogorsk, where there are likewise machine-shops, a foundry, and small saw-mills. This town is rapidly growing in importance. Along the Irtysh, the traveler will note the oil-tanks of the Russian petroleum companies.

Conclusion. While the Russian laws require that certain examinations be passed before a man is qualified to take direct charge of any given mine, there are no difficulties interposed by the Government to prevent the

actual control and direction of operations from being in the hands of foreigners.

Some of the requirements seem foolish and such will in time no doubt be abolished, but even these are not difficult of fulfilment. In the promotion of a mining property, a Russian company must be formed; but the entire shares of such a company may be owned, and all operations controlled, by foreigners. There are many old prospects and mines in different parts of Siberia that deserve further exploitation and no doubt many ore deposits that are as yet totally unknown. In the Urals the English copper companies have been particularly successful in opening up deposits of pyritic copper ore that previously were not known to be valuable for copper or were not known at all.

The higher price of the base metals in Russia makes this a very attractive field for this branch of mining. Thus copper is worth over 5 cents per pound more in Russia than in London, and lead and zinc also obtain higher prices. The higher prices of the base metals is caused by import duties and the fact that, up to the present time, the domestic supply does not equal the demand.

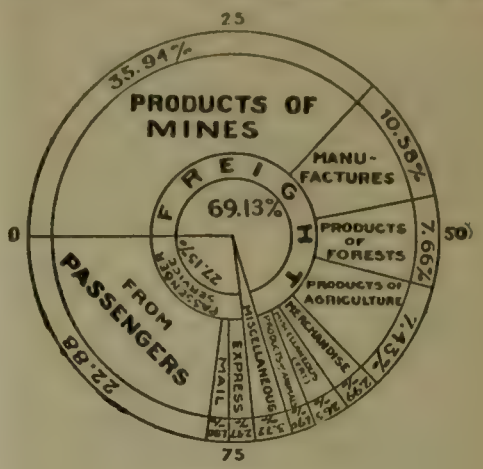
EXPERIMENTS on the treatment of Elm Orlu ores, Butte, Montana, covered a period of seven months. The ultimate aim was to make at the least expense the following marketable products: (1) A product for the copper smelter, containing, as nearly as possible all the copper, with some iron and a minimum amount of lead, zinc, and insolubles. (2) A product for the lead smelter, containing, as nearly as possible, all the lead, with some iron and a minimum amount of copper, zinc, and insolubles. (3) A product for the zinc smelter, containing, as nearly as possible all the zinc, with a minimum amount of copper, lead, iron, and insolubles. The gold and silver contents of the original ore were permitted to go with each of the above products in varying quantities. Treating about 450 tons per day, the average analysis of crude ore, concentrates, and tailing is as follows:

Product.	Copper, per cent.	Silver, oz. per ton.	Gold, oz. per ton.	Iron, per cent.	Zinc, per cent.	Lead, per cent.	Insoluble, per cent.
Original ore	0.73	6.23	0.013	3.29	18.52	0.75	62.23
Copper-iron conc.	2.25	21.01	0.04	19.78	22.78	13.01	2.30
Lead-iron conc...	1.13	18.91	0.04	9.99	9.15	50.60	5.05
Coarse-zinc conc.	1.96	14.74	0.035	9.15	47.77	1.88	3.47
Fine-zinc conc...	2.22	16.84	0.036	4.45	52.44	1.72	5.05
Tailing	0.07	0.60	0.0017	0.44	1.20	0.05	95.42

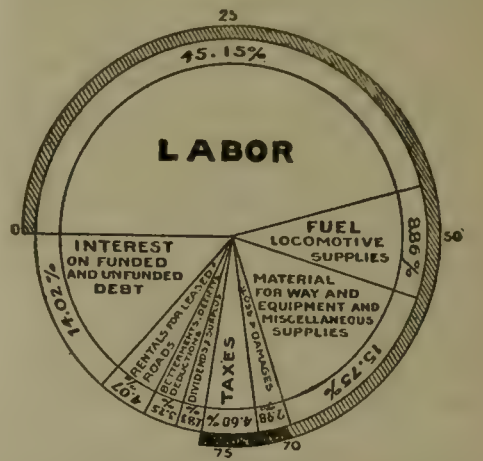
A comparison of the tonnage of concentrates and their analysis with the tonnage and analysis of the crude ore milled, shows an extraction of about 96% of the zinc and about 92.6% of the silver content of the original ore. The copper-iron concentrate goes to the Washoe works at Anaconda, Montana; the lead concentrate to the lead smelter of the United States Smelting Co. at Midvale, Utah; and the zinc concentrate to the zinc smelters at Bartlesville, Oklahoma, and Argentine, Kansas.

The Railway Dollar

WHERE IT CAME FROM IN THE YEAR ENDED JUNE 30, 1914



AND WHERE IT WENT,



AS COMPILED BY SLASON THOMPSON OF THE BUREAU OF RAILWAY NEWS AND STATISTICS.

In the period represented by the above chart the total revenue of railroads (225,486 miles) in the United States was $2,991,398,735. Freight contributed $2,061,262,870. In 1912, the aggregate capacity of 2,215,549 freight-cars was 82,965,418 tons, or 37 tons each. The railroads in 1912 moved products of mines totaling 566,538,387 tons. Of this, 315,581,446 tons was in the Eastern, 97,535,577 tons in the Southern, and 153,421,364 tons in the Western districts.

OILS from various regions are so well distinguishable by odor that it is frequently possible to detect their origin in this way. California oil has a smell somewhat like that of coal-tar oils; Pennsylvania oils have a gasoline odor; Texas and Russian products are similar; in the East Indies oil, an odor like that of cedar is detected; while Indiana, Ohio, and Ontario oils have a distinct sulphur smell.

Degree of Crushing to Free the Economic Minerals

By D. P. HYNES

MINERALS PRESENT. As a preliminary, all the important metallic and non-metallic minerals should be determined. A list can then be prepared showing the properties and the relative abundance of the minerals. Analyses are helpful. Qualitative and micro-chemical tests and petrographic investigation aid in identifying the species.

DEGREE OF CRUSHING. The crushing must be carried to the stage where no important quantity of the economic minerals remains included in grains of material from which the economic minerals are to be separated. Of course, the particular problem must fix the limit of the important quantity. In common practice, the stage at which the middling product disappears is taken as the degree of crushing necessary. When middling is composed of grains that include particles of economic minerals not freed, then the vanishing point of the middling is the degree of crushing. In many cases the middling is not composed of such grains, and this is usually true of fine material.

SCREEN-ANALYSIS. The first step is a screen-analysis of a sample of the ore crushed to a size somewhat larger than that which is likely to be the limit adopted. A set of screens having known openings should be used, and it is much preferable to use screens having a constant relation between the successive sizes, such as the Tyler standard testing-sieves.

CONCENTRATION TESTS. By making a series of concentration tests on a small scale by means of a little hand-jig and a pan, taking the products of the screen-analysis one at a time, with the object of making a tailing, a middling, and a concentrate for each size, the point of disappearance of the middling may be fixed. This may or may not correspond with the degree of crushing required, depending on the size and on the material.

SORTING TESTS. A method that will yield definite results in all cases consists in sorting the dried products of the screen-analysis, taking them one at a time. On material too fine to be sorted rapidly, a microscope is used for counting the grains of different classes.

For sorting, the apparatus required is a square of plate-glass six or eight inches on a side and a reading-glass mounted on a ring stand or other support. The method of procedure is as follows: Weighed samples are taken, decreasing the weights of the samples as the size becomes smaller. A sample is placed a little at a time on a glass plate and sorted into the several desired classes, which are accumulated in piles on separate pieces of paper or in receptacles distributed around the edges of the plate. From a small pile on one corner of the plate a number of grains are moved under the magnifying glass and examined rapidly. As the grains are determined, they are slid by the finger into the proper piles. When all the sample has been sorted, the classes are weighed. By this method, the waste obtained is clean waste, the concentrate is clean, and the middling consists only of included or mixed grains. By separating carefully a pile of each important mineral, and making a specific-gravity determination of each, useful information may be obtained.

When samples of all the sizes it is thought necessary to investigate have been sorted, the percentage of included grain material should be calculated for each size, and the results plotted to make a curve.

Sorting in this manner can be done on sizes down to 0.589 mm. or 28 mesh. Beyond this point counting is resorted to. A small sample is carefully prepared from each size. It is well mixed and small portions are spread on microscopic slides, one layer deep and not too crowded. A slide is placed under the microscope and examined with appropriate magnification. Taking a restricted portion of the field, say a quadrant defined by the cross-hairs, the total number of grains is counted and a note made; then the included grains are counted and the number recorded. The slide is moved and another field studied. When one slide has been finished others are examined in the same way. The work is trying, and the observer will have to rest at intervals, during which he will find it convenient to add the numbers set down for each class. The percentage of included grains may be calculated by number; and as only relative results are needed, the error introduced by considering numbers of grains instead of weights will not be serious. Counting should cover a sufficiently large number of grains to make the error of observation reasonably small. This may be checked by comparing the first half of the 'score' with the second half from time to time. When the results correspond within limits considered reasonable, work on that particular sample is stopped.

When the microscope is equipped with a mechanical stage, this may be used to advantage in counting the grains. The stage should be set so that its movements will be parallel with the cross-hairs. A slide is set on the stage and moved slowly parallel with the horizontal cross-hair. Only the grains that touch the cross-hair are counted. Several classes may be counted at once and the numbers recorded by scoring at the end of travel of the stage. The slide is then shifted by the other movement of the stage one or two millimetres and again moved parallel with the horizontal cross-hair.

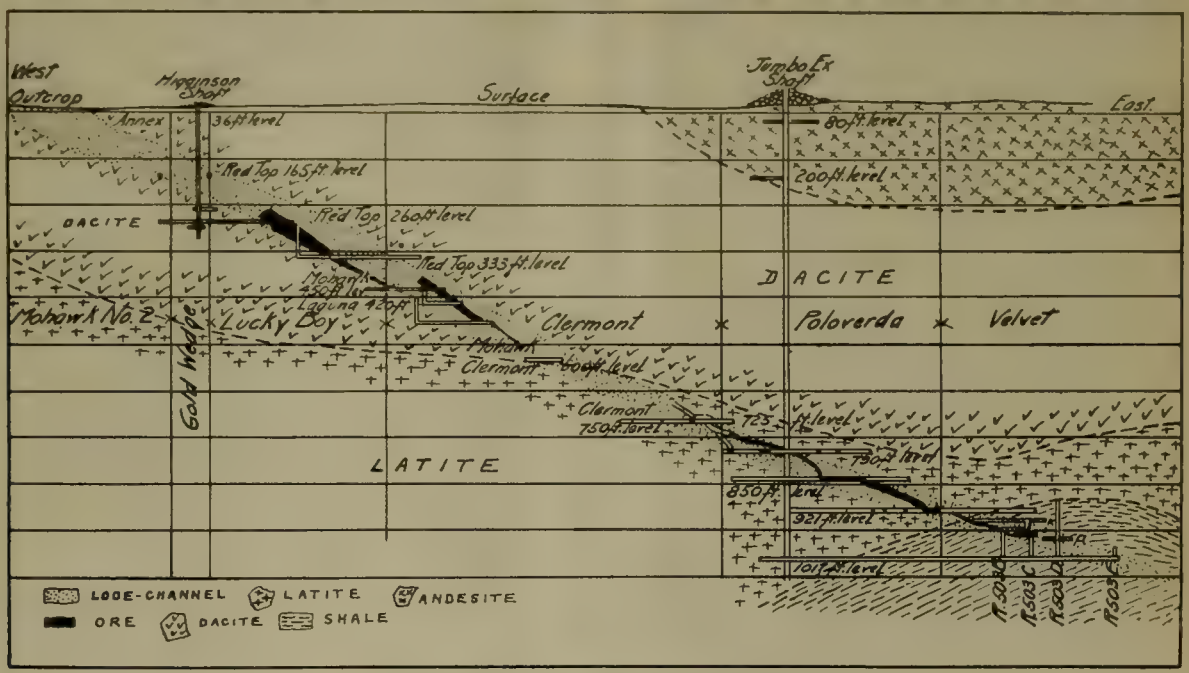
In making the sorting and counting tests, no work need be done on sizes that are far from the size likely to be fixed as that to which crushing must be done. It is, however, essential to draw conclusions from curves and not from isolated observations. I have used these methods, and find they yield very useful information.

Mining in the Shale at Goldfield

By J. K. TURNER

The discovery of pay ore in the contact-zone between the shale and latite has opened a new field for exploration in the Goldfield district, since the conditions revealed at the contact during the past few months were not heretofore known to exist. This condition, no less than the more recently ascertained fissuring of the shale, is likely to have an important bearing upon future operations in the district. Whereas until late in 1914 only one or two instances of fissuring extending into the shale, or below the shale surface, had become known here and no fissuring of the shale had been observed, more recent development has shown fault-action displacing the shale at varying angles, together with wide fissures of ore-bearing material extending far within the shale. Apparently, however, there is no essential analogy between the fault-plane and the fissuring of vein-matter, though an exception is found in the case of what has been described as the fold-fault in the Jumbo Extension mine, where the fissure has the dip into the shale of only 20 to 30 degrees.

Shale is found throughout the Goldfield district at varying depth overlying the basic alaskite or granite. On Vindicator mountain, in the north-central area, both the shale and alaskite are found outcropping near the peak of the mountain. In the southern part of the district the surface of the shale is found at a depth of 1750 ft. The shale, a sedimentary deposit, has offered a surface impermeable to mineralizing solutions, except where fissuring has taken place, although some silicification is apparent, for a negligible thickness, where the shale surface is in contact with vein-matter. Here silicification gives the shale the appearance of quartzite, and it is so classified by some authorities. There is no well-grounded supposition that the shale-latite zone will be found to contain pay-ore over the entire district, but developments up to the present time encourage the belief that valuable deposits will be found at many points in this zone where even low-grade lodes or ore-channels come in contact with the shale or extend within the shale.



CROSS-SECTION OF THE MOHAWK-JUMBO LODE.

The overlying volcanic flows, latite, dacite, andesite, and rhyolite, this being the order of their effusion, are more extensively fractured and show a considerable degree of fault disturbance, while the shale, being more compact in structure and apparently fractured only at wide intervals, offers, with its impermeable surface and comparatively flat bedding-planes, a condition favorable to the greater concentration of the metals.

The lode itself, with a dip of about 30°, follows, for varying distances, the contact-planes between the andesite and dacite, between the dacite and latite, and between the latite and shale, finally breaking through each in turn, but continuing for a greater distance along the shale-latite contact. This bears out the theory of greater resistance to solution and therefore a higher degree of concentration of the metals, in the sedimentary than in

the igneous formations of this and other districts.

Throughout the enriched area in the shale-latite zone, where it has been explored in the Jumbo Extension mine, the rich ore is found on the hanging-wall side. Between the rich ore and the shale is a mass of silicified latite, varying in width from 2 ft. to over 30 ft. A large part of this material is ore of commercial grade. Foot-wall seams of the rich ore have been found at a number of places in the mine, near the shale. Judging from the results of development work thus far in the contact-zone, it is apparent that the ore-channel upon coming in contact with the shale, seeks the deeper depressions or ravines in the shale's surface. The contour of this surface is most irregular and is marked by hills, ridges, and gullies, entailing a complex system of development.

In the Jumbo Extension mine the condition is presented of two distinct ore-channels, one overlying the other; the first extending along the contact-zone between the latite and shale, and the second in the form of a wide fissure, within the shale. The dip of this fissure is so nearly that of the bedding-plane of the contact that raises are driven from the workings in the fissure to develop the ore in the contact-zone, and this dip is so nearly flat that it is necessary to drive raises at frequent intervals to secure economy in stoping.

Further opportunities for interesting developments are offered at the contact of the shale and granite, the latter having been exposed at a depth of 1750 ft. in the St. Ives claim of the Merger Mines Co. Owing to its exceeding density it seems reasonable to expect an even greater concentration at the surface of the granite than upon the shale or in the other contact-zone near the surface.

AIR COOLING AND DRYING, whether the object be temperature or humidity control, has passed through the stages of free water contact, which in most important cases has been abandoned in favor of mechanical refrigeration. Numerous systems are in use where this cooling and drying has been performed by surface, city, or well water, and because the results have not been uniformly satisfactory either in obtaining the desired temperature or in reducing the humidity in the air to the proper degree for all seasons and weather conditions, they have been replaced by refrigerating equipment. All uncertainties and variations are removed by the substitution of mechanical refrigeration and yet its use is far from being as universal as it should and could be. In some classes of factory operation it has been found that the amount of labor performed by the workmen, especially in the summer months, was increased so much by mechanically-cooled breathing air that the expense of this cooling is more than offset by the greater output of the operators. For humidity control, by far the largest example of air-cooling by mechanical refrigeration is the Gayley process equipment for steel furnaces, the success of which is beyond question, and yet the application of similar equipment to other industries where humidity control is necessary or desirable is painfully slow.—*C. E. Lucke.*

Apex Litigation at Goldfield

As our readers are aware, the claim of the Booth against the Jumbo Extension has been compromised in an amicable spirit, which does credit to the two principals, Messrs. George Wingfield and Charles S. Sprague. In his geological report to the Jumbo Extension Mining Co., Mr. Horace V. Winchell summarizes the main facts in an interesting manner. We quote him as follows:

The principal veins of the productive portion of the Goldfield district occur about as shown on the above mentioned map.* Some of these veins have been large producers near the surface, and to the depth of about three hundred feet. The main vein is mineralized in lenses or shoots and has been followed downward upon its dip to the eastward for a horizontal distance of about two thousand feet and to a vertical depth of about thirteen hundred feet, thus indicating roughly an average dip of thirty-five degrees. The minor or subsidiary features, such as the old Jumbo vein, are about vertical and either die out or unite on dip with main dip. This main vein has a curved and irregular line of outcrop which is on the whole crescent shaped, and lies in the ground something like a saucer. In the case of such a vein it might be possible to start on the rim at more than one point and follow on the vein downward to the same orebody in depth. Legal rights depend upon the existence of a vein or lode and not upon the existence and position of shoots of high-grade ore within it. The vein may dip northeasterly and the ore shoots rake or pitch to the southeast within it, or the outcrop upon which the location made may have quite a different direction from that of the true strike of the vein; but the claim may still have extra-lateral rights so long as the vein can be followed generally downward between its end-line planes.

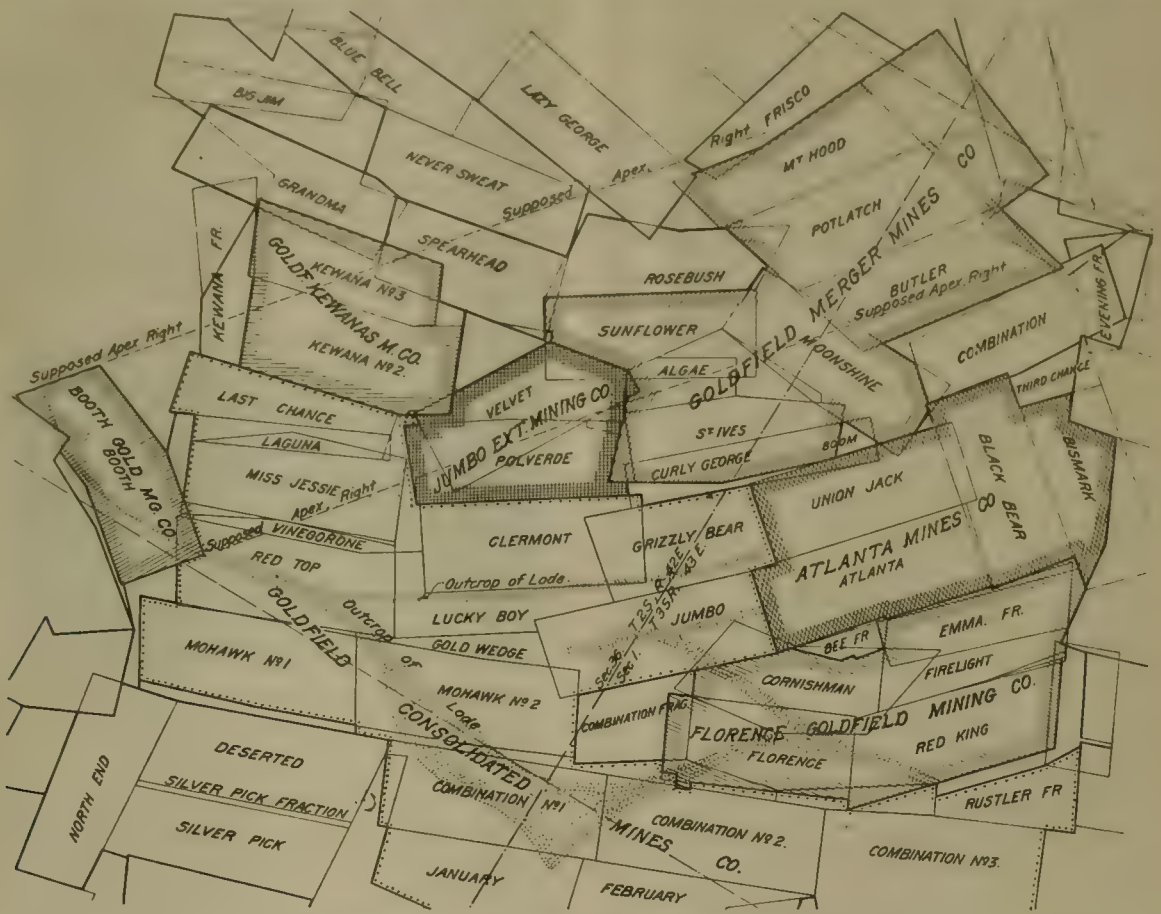
The horizontal distance from the outcrop of the vein on the Booth claim to the stopes in the Jumbo Extension ground is between 2000 and 2500 ft.; and the vertical difference in elevation is from 800 to 1200 ft., indicating (if we have the same vein in both) either a dip as low as 22 degrees or else that the vein is being followed downward on a course which is neither dip nor strike, but between the two. Observations in the ground show that the latter is the true situation. It is possible to pass downward through the Booth workings, to see the vein on the surface and on the various levels (not always well connected by raises on the vein) and to follow it along the strike with occasional interruptions due to faulting, through the workings of the Goldfield Consolidated by a devious and extended line of travel, to a connection on the vein with the Jumbo Extension mine. Absolute continuity has not been proved, and perhaps does not exist. Moreover, we travel for more than 1500 feet substantially on the strike of the vein, and pass out from the stretch of ground included within the extended Booth end lines, and yet our average course is downward; we arrive at stopes which are

*See next page.

within the Booth end lines extended, and we cannot doubt that we are on the same vein as that which outcrops on the Booth where we started. Throughout all this long belt of territory much time, money, and labor must be expended by the Booth in order to make its case positive, but it can probably be done.

Decisions in similar cases in Idaho which have repeatedly allowed extra-lateral rights more on the strike than on the dip, and have been affirmed by the higher courts, do not offer you much encouragement for contesting on that ground; and the uncertainly both as to the extent of the vertical displacement of the vein where it is seen to be faulted and as to the vein which the courts would take even if such faults were proved to be of considerable magnitude does not justify you in resting heavily on that hypothesis.

From the map it will be seen that an indefinite number of locations could have been made on the outcrop of the main vein in such a way as to include orebodies beneath the surface of the Jumbo Extension claims. As a matter of fact, such locations were made in the Mohawk No. 2 and Combination No. 1 claims, as well as in the Booth; and slight change in the direction of the east lines of the Florence, Combination Fraction, Red Top and other locations on the outcrop might have pointed them all, like the leaves of a fan, to one common centre or axis. In such cases it is held by the courts that seniority governs the oldest location has unquestioned right of way through all the others. Here the Booth has the advantage, for it was located on May 10, 1903, at least ten days before any other on the outcrop, and nearly four months before the Velvet (located Sept. 1, 1903) and more than five months before the Poloverda (located Oct. 17, 1903).



MAP OF THE CENTRAL PORTION OF THE GOLDFIELD DISTRICT.

DAKOTA SAND, on account of its uniform character and thickness over wide areas in North America, is not considered a prospect horizon of the first class for the finding of oil, except in some limited districts, according to L. G. Huntley in Bulletin 102 of the A. I. M. E. Where structural and other conditions are favorable for concentration of oil, the relatively more lenticular bodies of sand above the Dakota, particularly in the Benton and Niobrara, are more promising for the development of production than is the Dakota sand itself, save in several regions in Canada, where the most favorable areas are in the region underlain by the sand where it begins to play out and become lenticular.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Petroleum is from the Latin, meaning rock-oil.

Pine-tar oil is the most efficient flotation medium for Bisbee copper and Cobalt silver ores.

Normal faults are those in which the country-rock has moved downward on the hanging-wall side.

In the use of leather belting, the soft flesh side should be run against the pulley, giving a more pliable grip.

Casings of starting-rheostats for motors in gassy mines must be explosion-proof, as well as the motors.

Simultaneous blasting is estimated to be 25% more effective in breaking rock than the firing of holes consecutively.

The efficiency of a rock-breaker decreases rapidly when a reduction exceeding 4 to 1 is attempted, and the same holds true for rolls.

The simplest form of ore-dryer is a series of cast-iron plates over a flue, so that they can be heated by the hot gases from the fire-place.

Platinum is not used in tungsten filament incandescent bulbs, but its decreased use for this purpose has been more than compensated for by its use in jewelry.

Stope engineering covers the work of efficiency in underground mining, and in making reports and suggestions from time to time for betterment in operation.

Heavier wire, as a general rule, is better in screens when treating coarse gritty ore, but in the crushing of soft clayey ore it is advisable to employ screens having fine wire.

Nitroglycerin is a powerful heart stimulant; that is why the fumes cause a severe and prolonged headache when inhaled. The same effect is produced by handling dynamite cartridges with bare hands in hot weather.

Removal of rust from iron products is frequently necessary. Experiments in England prove that all chemicals tried for this purpose failed, as none would remove the rust without also dissolving some of the iron.

The terms 'drilled in' and 'completed,' when applied to oil-wells, are synonymous, and refer to a well that has been drilled through all the oil-bearing layers of sand so as to demonstrate that it is either a producer or a dry hole.

The cost of excavating earth with pick and shovel, and loading it, is about 40 cents per cubic yard for hard-pan; 20c. for tough clay; 15c. for ordinary clay, gravel, or loam; and 12c. per yard for light sandy soil—wages being reckoned at 15c. per hour in each case.

Water-pipes in cold regions should be laid in deep trenches to prevent freezing. In Nye county, Nevada, the Round Mountain company has just completed 45,336 ft. of 30 to 15-in. rivetted and lap-welded pipe for its gravel area. This was laid in a trench 42 inches deep.

Shovelers in the zinc mines of Missouri are paid by the number of cans filled. A can holds 1000 lb. The shoveler is paid about 10c. per can. At present some men are making $60 per week. One last week received $75. He must have handled about 375 tons of ore to 'can' this amount.

Geology was only taught in this country in 1830 at Yale, where Benjamin Silliman was professor, and at Columbia, South Carolina, where Lardner Vanuxem was appointed in 1821. The only textbooks available were reprints of Bakewell's geologies, annotated by Silliman, which appeared in 1829.

When employees wear proper clothing they feel comfortable and can work at their best. Many workmen readily recognize the common sense of thus adding to their efficiency while protecting themselves from injury. Others, however, will need to have these advantages pointed out to them in a friendly way; in some cases the foreman must use more forcible measures.

Asbestos is a potential life-saver. We do not realize, perhaps, that the fire-proof theatre curtain is made of asbestos, which is rock matter, but nevertheless almost as soft and pliable as cotton or woolen fabric. Asbestos has, of course, many other uses. Its incombustibility and its fibrous structure make it one of the most useful minerals for many and various structural purposes. It is used in making lumber, roofing, plaster, and stucco. Houses that are built largely of asbestos afford their occupants not only complete protection from fire because it is a non-conductor, but assure them also the comfort of freedom from extreme heat and cold. The asbestos-producing industry of the United States is growing. Some good mineral was discovered in Arizona last year.

Sub-level system of mining is only applicable in sections of a mine in which the orebody covers a considerable area, and has a height exceeding 100 ft. The development of the stope-laterals is necessarily expensive; the timbering is costly; and considerable expense is incurred in equipping and maintaining the drifts for motor-haulage. Unless the orebody is of sufficient area and height to repay the cost of the initial large expenditure, the sub-level system should be abandoned in favor of the hand-tramming system. The great advantage of the motor-haulage system is that it is capable of producing a comparatively large tonnage, not only in the operation of putting up the active stopes in the section, but more especially when reserve-drawing operations are started.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

WEAVERVILLE, CALIFORNIA

Dredging and Prospecting Gravel.—Golden Jubilee.—Asbestos Mining.—East Fork District.—Other Mines.

The Marysville Dredging Co. is testing the Valdor placer claims, below Junction City, with two Keystone drills. Several parts of the channel have given encouraging results. If the main deposit is worth it a dredge will be constructed before next winter. A. M. Elliott is in charge of the work.

The Trinity Dredging Co., operating the largest dredge north of Oroville, is digging good gravel near Lewiston. It is reported that new ground yields a higher average. H. E. Chesebro is manager.

Ten men are working in the Golden Jubilee quartz mine, at

CARRYING TIMBER TO THE GLOBE MINE, TRINITY COUNTY, CALIFORNIA.

Coffee. Ore is being extracted preparatory to a mill run. This mine was formerly a good producer. It is equipped with a good plant.

The Trinity Asbestos Co. is shipping material to its mines near the old centre of Cinnabar. It expects to start the sawmill soon. A large plant is contemplated. The company expects to start shipment of asbestos to San Francisco before the end of October. Seventy-five men are building a wagon-road from the mines to Castells, on the Southern Pacific railroad. It is officially stated that a large reserve of high-quality asbestos is blocked out. The company is largely composed of Oakland people. H. A. Mecum is manager.

The East Fork district, tributary to Helena, is attracting more interest with the arrival of warm weather. The Enterprise continues to produce well, and the 10-stamp mill is running on ore of excellent grade. The vein is about eight feet wide. Arrangements are being made to open promising ground below the main workings. Water-power facilities have been improved. R. A. Skinner is manager.

Developments are proceeding at the Bonanza, Oversight, Yellow Jacket, Hoodoo, and other properties. Most of the new work is designed to intersect at fair depth rich shoots exposed near the surface. Large quantities of mill ore are developed at several mines. A custom mill is being urged by operators.

The Marysville Dredging Co. has started another Keystone drill at work prospecting the ground of the Valor Gold Mining Co. below Junction City.

CRIPPLE CREEK, COLORADO

District Quiet but Sound.—Dump Mining.—Sharpe, Ajax, and School Lessees.—Milling.—Dividend.—Split-Check Leasing.

During the past 10 days the Cripple Creek district has been quiet. Nothing new has occurred in the way of mergers and the regular producers have been operating without making any new discoveries. The warm weather has brought out a great number of surface and dump lessees, so that the tonnage is undoubtedly increasing, though the average value of the ore shipped will be lower for June than it was in May.

The old Gold Coin dump, the site of the old Economic mill, has been fitted up with a loading device and 100 tons per day is being shipped to the Copeland sampler. This material is averaging about $5 per ton, so that unless the indirect advantage of keeping the sampler busy is calculated, it is hardly profitable at the minimum freight and treatment charge of $4 per ton.

The Sharpe lease on the Elkton mine dumps is doing well, the sorted ore averaging nearly $20 per ton. This is probably the best dump lease here.

Lessees on the School Section No. 8, at Cameron, are shipping steadily from the 400 and 500-ft. levels a good tonnage of medium-grade ore. This property has been a consistent producer for the past five years. Judging from present conditions it will continue to do so for some time to come.

On June 10 the Golden Cycle Reduction & Mining Co. paid its regular dividend of $30,000 from May earnings. This is the promised 2% per month. It is hinted that from the present volume of business this earning may be increased in the near future.

Lessees on the 1200-ft. level of the Ajax mine have cut a body of ore two feet wide, assaying $60 per ton. This is greatly encouraging to the management, as the property was recently opened to lessees after the company had ceased work. A number of lessees are now at work in various parts of the mine and good earnings are expected.

Lessees on the Blue Bird are doing well, a good production is being maintained. Here an interesting variation of the 'split-check' system is being tried out. The mine is leased from the owners at a flat royalty of 20%. The lessees then sub-lease on the split-check basis. On the net returns, then, to any certain sub-lessee, 20% is first deducted for the owners, then the balance of the check is divided equally between the lessees and the sub-lessee. The lessee furnishes all supplies, while the sub furnishes labor only. It is fairly obvious that a good grade of ore must be produced to stand such a charge.

LEADVILLE, COLORADO

Dredging Near Leadville.—Possibilities of Prospect Mountain, the Valley Adit.

It is officially stated that the Derry Ranch Gold Dredging Co. was incorporated here a few weeks ago to operate the first dredge in Lake county and in the Leadville district. The company is composed of A. C. Ludlum of New York, R. F. Lafferty, general manager, O. M. Lafferty, John Nisbet, and Frank E. Purple. The capital is $100,000. The property includes the old Derry ranch, south of Leadville. A dredge has been under construction for some time, and is now nearly complete. The

boat is patterned after those in California. The hull is 107 ft. long and 42 ft. wide. The buckets are of 5½-cu. ft. capacity, 22 dumping per minute. Great interest is being taken in the results of this dredge. The ground has been well tested, and those interested consider the area in the Arkansas and Lake Creek valleys will prove to be the richest in Colorado. Dredging is expected to commence at the end of August.

The Valley adit that is being driven into the foot of Prospect mountain by Warren F. Page is an important work for the district. The course of the adit is toward an immense and unprospected area lying immediately north of Big Evans gulch, comprising a territory about six miles square in what appears to be the richest mineralized portion of the camp. The portal of the adit is on the famous Valley claim which has produced a good deal of money within the past few years, and continues to add materially to the output of the district. The ground immediately south of the adit includes such mines as Silver Spoon, New Monarch, and Cleveland. Mr. Page who is one of the best known mining men of the Leadville district has been active in the Big Evans region for many years, and recently had charge of the operations on the Valley and Silver Spoon. From these mines he had diamond-drill holes driven into the formations to the north, which lie under Prospect mountain and the upper reaches of Canterbury hill. In these holes ore was cut in several places. He immediately started driving the Valley adit along the course of the drill-holes. The adit is now in 1150 ft., in the porphyry and mineralized formations of the district.

Ore is expected almost any day now. Work in the adit is being done in a modern and efficient manner. Electric power will be installed and all of the transporting of material will be done with locomotives. Mr. Page is especially careful about timbering, stating that he wants every stick of timber that is erected to be in good condition 10 years hence. If this work discovers important orebodies, the effect on the mining situation in the Leadville district will be considerable. Something new is wanted. Prospect mountain is full of possibilities. It lies in a direct line with the ore-shoots mined on Fryer hill, Evans gulch, and on Jonny hill. What veins are found will of course be deeper.

AUSTIN, TEXAS

NON-METALLIC MINERALS, GRAPHITE, SOAPSTONE, IRON OXIDE.—STATE MINERAL PRODUCTION.

Development of the mineral deposits that are known to exist in the Llano region, north of Austin, is being urged by William B. Phillips, director of the Bureau of Economic Geology and Technology of the University of Texas. He directs particular attention to the possible commercial importance of the graphite deposits. These deposits occur along the line of the Austin & Northwestern railway from Austin to Llano, between Kingsland and Llano. Good graphite also occurs in Burnet county a few miles west of the town of Burnet. At neither locality has anything been done, although some of the material is flake graphite, a variety that always commands a ready and profitable market. Another mineral in Llano county is soapstone. This is suitable for stationary wash-tubs, laboratory and chemical desk-tops, stones for fireless cookers, etc. One of these deposits is north of the town of Llano and east of Valley Springs. The other is east of Llano about seven miles and near the Llano river. Some of these stones have been under examination. They saw easily, have close and dense structures, and a crushing strength of 3000 lb. per square inch, with a weight of 169 lb. per cubic foot. They are practically fireproof.

Beautiful purplish red oxide of iron occurs in Mason county. This makes good paint. It grinds to an impalpable powder, has a soft and greasy feel, takes oil well, and has a fine appearance.

The total value of the mineral products of Texas from 1882 to the end of 1914 is nearly $300,000,000. Of this, petroleum accounts for about 36%, clay products 16%, and stone 4%. No other mineral amounts to 4%.

MIAMI, ARIZONA

INSPIRATION NEW MILL.—MIAMI ALTERATIONS.—OLD DOMINION MINES, MILL, AND SMELTER.—IRON CAP AND COLE.—FERRY ON SALT RIVER.

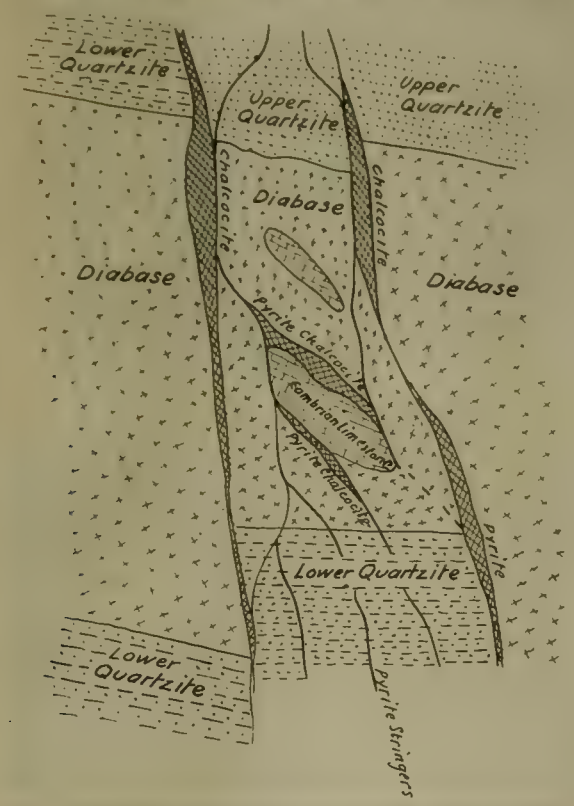
Probably before the end of June three of the eighteen units of the Inspiration concentrating plant should be treating about 850 tons each per day. The other units will be started as they are finished. It is reasonable to assume that the operation of the first units will have a decided influence on parts of the treatment scheme and equipment in the units to be put into commission later, so it is likely that there will not be the same rush in starting the last ones that has characterized those nearly ready. The 600-ton test mill that has been in steady operation for the past 17 months has admirably fulfilled the purpose of its erection and operation, namely, determination of the most economical flow-sheet it was possible to install in the main concentrating plant. Yet this can be made with greater accuracy by operation of one of the units of the mill proper.

A parallel case can be noted in late reports as to the part remodeling of certain units of the Miami Copper Co.'s mill. In No. 6, as a result of modifications of the flow-sheet, it has been found that a better recovery of copper can be made than is possible in any other units, with all working on the same class of ore; consequently the others are to be made to conform to the flow-sheet of No. 6. Considering the high recovery anticipated at the Inspiration mill, the flow-sheet may be regarded as extremely simple compared with those of the porphyry copper mills that have been erected in recent years. Apparently oil flotation and improved grinding methods have been the potent factors in developing this simplicity.

The Old Dominion company had two furnaces in blast up to June 10. A third was then started. Copper production of the plant has been averaging over 40 tons per day. Most of the smelting ore has been from the Old Dominion and United Globe mines. This is hoisted through the A shaft. There is an ever-increasing tonnage from custom ores and from lessees. The basic converter-shell, if it remains in blast for the remainder of the month, will have completed a campaign of two years without having been off the stand. In the concentrating plant over 600 tons of ore per day has been treated through June. Most of this is from the A shaft. There is also some concentrating ore being received from the Arizona Commercial. During the present week a new type of shaking-screen will be installed below the trommels at the head of the mills. In the near future extra compartments will be added to the Woodbury jigs. Recent changes made in the flotation machine have allowed of a considerably larger tonnage being treated. In the mine department the tonnage hoisted this month has averaged between 900 and 1000 tons per day. The flow of water in No. 12 level has decreased to about 6,500,000 gal. per day. This decrease has enabled the shutting down of the Prescott pump on the No. 10 level, so that all of the water is now being handled on No. 12. Considerable increased exploration work has been started since the first of June. The 10th level east is being driven to connect with the Gray shaft. The 14th east foot-wall drift is also being advanced east as rapidly as possible to explore new country. The haulage shaft off the Buffalo cross-cut has been connected from the 12th level of the Old Dominion to the 7th level of the Gray, thereby greatly improving ventilation and expediting the handling of ore and waste in that territory. The work on the pocket below No. 16 level is progressing well, the steel pocket is now being put in. It is expected to have this work completed and ready for use early in July. All waste is now being hoisted in skips and the new installation is working satisfactorily. A

small churn drill is putting down a hole from No. 16 to No. 18 level for ventilation. It is expected to commence unwatering the 18th level at the A shaft within the next two weeks. As soon as the electric pumps are working again the extraction drift going west on No. 18, which is already over 400 ft. from the shaft, will be started. A drift will also be started toward the centre orebody. A sump below the shaft on No. 18 level still remains to be cut. The Buffalo mine is maintaining its normal output. Advantage is being taken of higher copper prices to sort over and ship any ore still remaining in the old surface dumps. On the surface the water-well west of Pinal creek is nearing completion, and an air-lift will be installed in the near future to test the capacity of the hole. The necessary air-line has already been laid to it. A new slime-pond, for settling slime from the mill, is nearing completion west of Pinal creek, below the Miami road.

The Iron Cap is shipping 200 tons of 10% ore per week to



IDEAL CROSS-SECTION THROUGH THE OLD DOMINION IN THE LOWER LEVELS OF THE CENTRAL PART OF THE MINE.

the smelter at El Paso. On June 14, shipments of high-grade ore to that place was begun with a carload that averaged 25% copper, 25 oz. silver, and a small amount of gold. The mine's force numbers about the same, but development work now beginning will probably result in employment of more miners in the near future. A winze is being started down from No. 8 level for the purpose of prospecting that level. If the winze remains in ore the shaft will be sunk to that level and the property opened thoroughly at the latter depth. Between the winze and the end-line (identical with the west end-line of the Arizona Commercial) the ground opened has an excellent appearance. In one place the high-grade ore averages six feet in width. The stope on the 8th level looks good.

At the Cole Development a few men are employed at present, their work being devoted wholly to extracting shipping ore. Work is being done on No. 1 and 4 levels. Fine chalcopyrite ore is being taken from the lower level.

Supplies for a cable-ferry that he will install across the Salt river to Camp Sunset, at the mouth of Buckhorn canyon, about 4½ miles below the Roosevelt dam, have been secured in Miami by Mr. Baker. The ferry will consist of a flat-bottom boat, 20 ft. long and pointed at both ends. As its work increases, a scow-ferry will be used that will carry a team and wagon across the river. A 900-ft. cable will be used. It will be arranged in such a manner that the current will carry the boat and its burden across in either direction. Excavation and leveling for the new campsite has been completed. A site for a blacksmith shop has also been provided for. Sufficient room for a small planing-mill also has been arranged. Work at Camp Sunset to date has been mostly of a preparatory nature, but after the ferry has been completed regular development of the gold and copper claims owned by Baker and Ferryman will be advanced steadily. The gold prospects owned by them in Buckhorn canyon have encouraging surface showing. They have been worked over an extensive area in a superficial manner by early miners. Some of the free gold brought in from the district resulted in many locations of claims there by Globe and Miami people.

TORONTO, ONTARIO

PROSPECTING AND DEVELOPMENT CURTAILED BY FINANCIAL DEPRESSION.—HOLLINGER, MCINTYRE, AND PORCUPINE IMPERIAL.

The effect of the War and financial depression on the mining industry has been very noticeable in connection with the recording of claims in the mining areas in the West, under the jurisdiction of the Department of Mines at Ottawa. Prospecting has fallen off greatly. Last year it was active. Experienced prospectors had no difficulty in getting grubstaked. During the year ended May last 12,000 oil claims, and over 2000 mineral claims were filed with the Department. These were all for discoveries made before the War, and there is now a marked decrease. Another indication of how the industry is being retarded for want of capital, is the large number of applications which are being received for an extension of time for the work on claims required to be done during the first year. Important discoveries of oil have been made around Great Slave lake, but for want of capital the claims remain undeveloped.

The earnings of the Hollinger for the four weeks ended May 20 show a considerable falling off from the average, due to the shortage of power in April, which retarded development at that time. Since then, the endeavor to keep up development has resulted in the extraction of considerable quantities of low-grade ore, reducing the average value of the ore treated. Gross profits for the period were $139,187, from the treatment of 23,821 tons that averaged $9.56 per ton. Working costs were $3.54 per ton. In addition to this tonnage the Hollinger mill treated 10,291 tons for the Acme.

Directors of the McIntyre recently visited the mine. They returned well satisfied with its prospects. At the 600-ft. level from No. 4 shaft, the orebody is 26 ft. wide. It is reported to average $10 per ton. On the north side of the property No. 5 shaft is down 400 ft. The vein, which has been opened up for 150 ft., is 30 ft. wide in some places. The diamond-drill has proved the vein to a further depth of 100 ft. The shaft is being sunk deeper. Production during May was approximately $59,000.——At the Porcupine Imperial the vein on the 100-ft. level has been opened for 25 ft. from the old workings. It shows an average width of 5 ft., assaying about $13 gold per ton. The orebody will be prospected at depth by diamond-drilling. Thomas Sloan, formerly of Nevada, is mine manager. ——The vein of the Porcupine Crown has been found beyond the second fault on the 200 and 300-ft. levels. Driving is under way in high-grade ore. The vein has also been cut on the 500-ft. level.——The Chambers-Ferland has made connection with the northern workings of the Nipissing at 350 ft. This will give ventilation to the drifts of both companies.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Though it is the purpose of the U. S. Geological Survey to extend its investigations to all parts of Alaska, it sometimes happens that it is impossible to do geologic work in advance of actual mineral discoveries by the prospector. The Survey, however, attempts to follow up the reported new discoveries of valuable minerals by surveys and investigations as soon as means permit. A report on work inspired by the discovery of gold in the Innoko district in 1906 has been issued as Bulletin 578, entitled 'The Iditarod-Ruby Region, Alaska,' by Henry M. Eakin. The investigation seems to have developed the fact that geologic conditions favorable to the occurrence of auriferous deposits are repeated in many places in this part of Alaska. This augurs well for the future of the mining industry in this region, notwithstanding that the workable gold placers so far developed are limited to comparatively few small areas.

Chisana

There are about 250 men at Chisana. New deposits of gravel have been found to encourage them, especially the deep ground on Dry creek. It is said that Dawson will get the Chisana business this season, as freight can be hauled cheaper than from Cordova.

Juneau

On June 11 the 2500-ft. adit for the Alaska Gold Belt company, in the upper Sheep Creek basin, was started. Thirty-five men will be needed. Arthur Riendeau is in charge. The general manager, A. B. Dodd, will have from 40 to 50 men at work prospecting and constructing.

On June 15 a large cave-in occurred at the Alaska Treadwell mine. The bottom of the old 750-ft. level dropped to the level below. Waste that had been dumped into the old open-cut for 10 years went through into the old workings. Over 100,000 tons of ground fell, resulting in a decided shock to the district. Not much damage was done. Pumps at 750 ft. were put out of commission.

Seward

The geology and mineral resources of Kenai peninsula have been investigated by expeditions of the U. S. Geological Survey since 1898, and results have been made public in several reports. All this information has now been co-ordinated and summarized in a new publication entitled 'Geology and Mineral Resources of Kenai Peninsula, Alaska,' by George C. Martin, B. L. Johnson, and U. S. Grant, issued as Bulletin 587. Kenai peninsula contains auriferous lode-bearing areas of some promise, though deep mining has so far been done on only a small scale. Auriferous gravels are widely distributed in the northeastern part of the peninsula and have been mined in a small way for 20 years. The future of placer mining on the peninsula depends on the exploitation of many large bodies of gravel containing too little gold to permit development by the simple methods thus far chiefly used. On the Cook inlet side of the peninsula there are very large deposits of lignitic coal which, though now almost entirely unused, are a possible source of power, and hydro-electric developments are also possible at several places on the peninsula. Seward, the principal town on the peninsula, has been chosen for the coastal terminal of the Federal Government railroad which is to be built to Fairbanks.

Valdez

The valley from Keystone canyon to the head of Lowe river has been staked by prospectors. A Keystone drill is to be used. Good prospects are expected.

ARIZONA

Cochise County

The Copper Queen company is to concrete the Sacramento central hoisting shaft from the 1700-ft. level to the surface. Hoisting will not be interfered with. The compressed-air system of laying the concrete will be used. Work will be aided by skips and cages, no platforms being necessary. George Meyers, master mechanic, will be in charge. At the Uncle Sam shaft the new steel head-frame is complete. An engine-house is under construction.

Mohave County

Dividends paid by the Tom Reed company in the year ended March 31, 1915, totaled $554,828, or 61c. per share. Since September 1910, the company has paid 57 dividends, totaling $2,401,311, or $2.61 per share issued. This sum represents approximately 4½c. per share per month for a period of nearly five years.

The Orion Mining & Milling Co. has acquired the Victor-Virgin property. Over 3500 ft. of work has been done. The main shaft 550 ft. deep, is to be unwatered. Several other deep shafts have been sunk.

CALIFORNIA

Nevada County

The new steel head-frame at the Central shaft of the North Star mine is being erected. It will be 100 ft. high. Foundations for the hoist are being prepared. It will haul 4-ton skips. Steel bins and a sorting plant are included in the new structures.——Work is to be resumed at the Columbia mine where three men were killed two weeks ago.——Vigorous development of the Cassidy continues. The veins in this property are parallel with those in the Empire and Pennsylvania.

Placer County

Development at the Mayflower near Forest Hill is encouraging.——The Rossi, in the Iowa Hill district, is being examined for sale.——Canada Hill claims are being investigated by Grass Valley people.——The old Black Oak near Weimar is being re-opened.——Placer miners continue washing on the American and Bear rivers.——Some rich gravel has been opened by the Federal Drift Mining Co., operating near Dutch Flat.

Plumas County

A nugget worth nearly $600 was unearthed by B. Turney on Squirrel creek last week. The same claim yielded good nuggets last year.

Shasta County

On June 19 the Noble Electric Steel Co. shipped 60 tons of ferro-manganese from its smelter at Heroult. Seventy-five men are employed.——It is reported that the Bully Hill company will soon be ready to produce a fair quantity of zinc.

Tuolumne County

(Special Correspondence.)—Development of the Knox and Boyle, Miller and Holmes, and Gray Eagle and Nyman claims of the Nyman Consolidated Mines Co. is very encouraging. The Knox and Boyle vein was recently leased for development. Ore from the 300 and 400-ft. levels has been mined and milled. As a result of the first mill-run in May $8.52 per ton was recovered by amalgamation. Work extended to the 600-ft. level has opened a vein showing good ore across the full face of the drift. A stope has been started south of the

shaft where the work is being done on two shifts, and ore is sent to the mill. The unwatering of the main three-compartment shaft was begun last week. The Nyman or west vein will be developed from the 600-ft. level, thereby opening two additional orebodies. C. E. Shafer is in charge.

Jamestown, June 18.

YUBA COUNTY

The Yuba Construction Co. at Marysville has secured a contract from the Yuba Consolidated Gold Fields Co. to construct a dredge. It will be larger than No. 14 now operating on the Yuba river.

BUCKET-LINE OF YUBA NO. 14 DREDGE.

COLORADO

CLEAR CREEK COUNTY

A large number of miners and lessees are busy at the Capital mine. Bruce & Co. has 18 in. of galena, 13 tons from which netted $100 per ton. DeMasters & Co. had 150 tons treated at the Capital mill. Hummer & Son continues to ship $25 ore to the Salida smelter. Connection between the Kane adit and Capital adit is an event in which all are interested. It will improve ventilation and open new ground.

The Terrible-Dunderberg Mining & Power Co. has outlined a big development scheme for the season at Silver Plume. The mill is being overhauled for 100-ton capacity.

The mill at the Mineral Chief on Democrat mountain is nearly ready to start.

DOLORES COUNTY

In May the Rico Wellington company shipped 42 cars of ore. The profit was about $5000. The Rico Consolidated marketed 14 cars.

GUNNISON COUNTY

There is considerable mining activity in this county.——At Ohio City the Carter Mining Co. is employing 55 men. Some leases have been let, and good ore is being extracted.——The Anaconda company, near Spencer, is shipping regularly.——Arrangements are under way to resume work at the Vulcan and Good Hope at Vulcan.——The shoot in the Carbonate King above Ohio City is producing 40% zinc ore.——A large body of zinc carbonate has been opened in the Doctor mine, 20 miles north of Gunnison.

LAKE COUNTY (LEADVILLE)

On June 13 pumps in the Penrose shaft were down 380 ft. They are lowering the water 5 ft. per day of 24 hours. The flow is about 2500 gal. each per minute. Everything is working well.

Owing to the pipe from the furnaces of the Western Zinc Oxide Co. to the bag house becoming nearly choked with oxide, the plant has been closed for a clean-up. Twelve tons of oxide was saved.

Lessees at the Ponsardin are endeavoring to find a market for the ore from their new shoot. Samples were sent to several smelting interests.

SAN JUAN COUNTY

The Silverton district shows the following activities: at a meeting of county mining men it was decided to organize a cyaniding company with a capital of $50,000. Of this, $10,000 would be raised to purchase machinery to be installed in one of the plants in the district. For a start the capacity would be 40 tons per day.——Lessees at the Silver Lake are ready for a busy summer. The mill has been started.——At the Bagley, above Animas Forks, lessees have a good deal of ore ready for the mill.——The Peerless San Juan company's property was examined last week by G. T. Milliken.——Work is encouraging at the Queen City, Bandora, Golden Fleece, and Pride of the West.

IDAHO

SHOSHONE COUNTY (COEUR D'ALENE)

Lead, zinc, and copper mines around Mullan are in good condition. Included are the Morning, Hunter, Snowstorm, National, Reindeer-Queen, and Carbonate Hill, all properties with excellent futures.——The Hercules-A. S. & R. smelter contract dispute is still unsettled, and the mine and mill remains closed.——Lead and zinc ores are being mined in the Terrible-Edith near Murray.——The Frisco is shipping a carload of zinc concentrate daily.——Good progress is made with the H. E. M. mill building near Wallace.——After paying its June dividend the Success company had $61,492 cash on hand. The main shaft is down to 1200 ft.——In the Pandora-Snowstorm dispute, the former company was allowed to inspect the latter's mine without an order from the district court, as was asked. The 600-ft. level of the Snowstorm was found to be 180 ft. into Pandora, with north and south cross-cuts 50 ft. each way.

MICHIGAN

HOUGHTON COUNTY (THE COPPER COUNTRY)

On June 12 the Calumet & Hecla distributed its promised bonus to employees of $500,000. Over 8000 people were recipients. It was also pay-day, and about $1,000,000 was circulated.

Isle Royale is shipping 2500 tons of ore per day to one head of its own mill, and at the Tamarack, Franklin, and Allouez-Centennial plants.

At the Osceola the power-plant at No. 3 North Kearsarge shaft has been re-constructed. The shaft is being repaired.

The Hancock mine is producing 300 tons of ore per day. Shipments to the Franklin mill have been doubled since the beginning of June.——Another large lot of mineral (60% copper) has been sent from the White Pine mill to the C. & H. smelter at Hubbell.

MISSOURI

JASPER COUNTY

The record output of ore from the Missouri-Kansas-Oklahoma district was during the week ended June 12. The total was

$1,048,349. A year ago this week's yield was worth $259,703. Average per week for 16 years is $238,863. As high as $135 was paid for zinc concentrate assaying 60% metal, $82 for calamine, and $75 for lead. The output was as follows:

District.	Blende, pounds.	Calamine, pounds.	Lead, pounds.	Total value.
Webb City-Carterville	6,557,350	63,090	838,260	$442,318
Miami	2,697,280	.....	721,330	153,260
Joplin	1,894,090	65,000	181,800	122,680
Duenweg	1,098,760	52,280	.....	70,757
Galena	1,156,700	.....	11,510	66,830
Granby	1,248,220	295,690	.....	59,900
Alba-Neck City-Purcell	626,830	.....	.....	37,320
Oronogo	649,820	.....	.....	31,812
Lawton	523,910	.....	.....	24,246
Belville-Klondike	356,870	.....	.....	19,580
Aurora	.....	249,100	.....	7,440
Spring City-Spurgeon-Saginaw	13,720	125,000	.....	5,310
Cave Springs	65,460	.....	.....	3,520
Wentworth	56,840	.....	.....	2,800
Peoria	.....	.....	16,900	576
Totals	16,945,850	850,160	1,769,800	$1,048,349

For the first 24 weeks of 1915 the total value is $10,086,668.

On June 10 the Longacre-Chapman mine at Neck City was flooded with water and mud. Seven men were working. One escaped the rush. A large number of miners worked to rescue the others. Four of them spent 120 hours in a small drift nearly full of water. They were saved. The other two were in the mine up to last reports.

Last week three miners were killed and two injured in the Little Martha company's mine at Joplin. Above the 160-ft. level a huge slab of lime and flint fell, with the above result. Eleven others had narrow escapes.

Owing to the tremendous activity in new and old mines in the district, underground work is likely to become more carlessly done in the effort to extract zinc ore for the high market. The mine inspectors will therefore be busy for some time keeping workings up to the mark.

MONTANA

Silverbow County

The Western Federation of Miners is entitled to control the property of the Butte Miners' Union No. 1, but is restrained from disposing of any of the property, money, or records belonging to the union, according to a decision of district Judge J. B. McClernan made at Butte on June 12. The decision defeats the attempt of local union officials to oust the officials of the Federation from any participation in the affairs of the Butte organization.

While the Poulin shaft of the Anaconda company is being sunk and development done, hoisting of ore will be suspended. This shaft is 1500 ft. deep, and has supplied 250 tons per day.

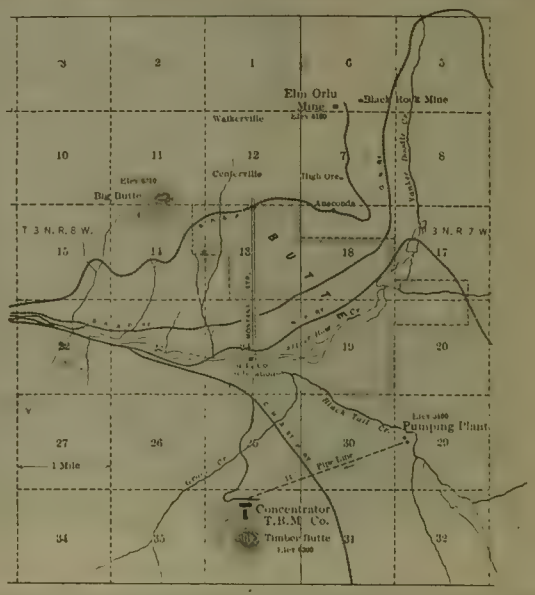
In its statement to the County Assessor for the year ended June 1, 1915, of the Anaconda Copper Mining Co. the following is included: ore extracted, 3,311,488 tons; gross value, $8.941 per ton; operating costs, $6.137; net profit, $6,468,439. Out of the total revenue of $29,608,185, employees received $11,779,233.

The North Butte companies statement shows that 262,815 tons of $9.828 ore gave a profit of $333,740.

It is planned to start work again at the Tuolumne. Butte people, headed by the mayor of the city, have acquired the Bonanza claims in the Walkerville district. Some good ore was opened in the property a few weeks ago. The shaft will be sunk 200 ft. deeper.——The Lexington mine is to be re-opened. ——Lessees in the district are busy.

The concentrating plant at the Timber Butte Milling Co., is described in Bulletin 102 of the A. I. M. E. by Theodore Simons of Butte. The mill was erected to treat ore mined at the Elm Orlu mine of the Elm Orlu Mining Co. This ore contains zinc and lead in sphalerite and galena; copper in bornite, chalcocite, tennantite, and tetrahedrite; and gold and silver either free or chemically combined with the sulphides of the base metals. The gangue is chiefly quartz, barite, fluorite, rhodonite, and rhodochrosite. The iron in the ore occurs as iron pyrites.

The Elm Orlu mine is situated near the northern border of what is locally known as the Butte sulphide-copper belt, about one mile north of the Anaconda mine, and adjoining the Black Rock zinc mine of the Butte & Superior company on the southwest. The mill is on the northern slope of Timber Butte, a



MAP OF BUTTE AND SURROUNDING AREA, SHOWING PLANT OF TIMBER BUTTE MILLING CO. AND ORE AND WATER-SUPPLY.

prominent topographical landmark in the Butte district. This site permits to a large extent the gravity system of ore flow; it presents a convenient and extensive area for a tailing-pond; and it is comparatively near to the source of water-supply and to existing railroads.

The mill is 4.5 miles from the mine in an air-line, or 13 miles by rail. The ore is loaded on railroad-cars at the mine, taken over the B., A. & R. Ry. high line to Rocker, and thence by the Chicago, Milwaukee & St. Paul railroad to the Timber Butte exchange, a siding on the Milwaukee line where it crosses Montana street, a distance of 11 miles. From this siding the cars are hauled, two at a time, to the mill by an electric 400-hp. Baldwin locomotive, a distance of two miles. The concentrate is taken from the mill to the sidings of the Milwaukee or the Northern Pacific line where the respective railroad companies receive it for transportation to the smelters. A description of the mill covers 20 pages, and is of great interest.

NEVADA

The report of the Nevada-California Power Co. for 1914 has been published. Power is generated at Bishop, California, and transmitted to Goldfield, Tonopah, and other Nevada districts. The revenue was $960,431; operating expenses, $515,897; surplus after adding other income and deducting interest, $319,964; dividends, $200,000; surplus at end of 1914, $1,504,784; and surplus at end of 1913, $1,451,263.

Churchill County

At Job's Peak, 35 miles from Fallon, Cirac Bros. have discovered ore. The ground is encouraging. A number of claims have been staked.

Esmeralda County

(Special Correspondence.)—The Jumbo Extension mine is

shipping 100 tons per day to the local sampler of the Western Ore Purchasing Co. Thirty 50-ton cars had been shipped in June on the 21st, mine assays giving an average value of $58 per ton. Up to that time the controls were $5000 above the mine assay value of production for the month.

In the main stope of the Atlanta mine, at an approximate depth of 1620 ft., ore averaging $30 per ton is being broken across 15 ft., with an additional 15 ft. exposed that assays from $10 to $20 per ton. Shipments are made at the rate of 50 tons per day.

The Merger M. company is driving east at a depth of 1175 ft. in the northern part of the St. Ives claim, following the shale contact in quest of the southern projection of the Jumbo Extension ore-channel. Work is advancing rapidly at this point. Better assays are being obtained in the drift.

Goldfield, June 20.

At 300 ft. in the Black Butte at Goldfield, a cross-cut has entered the vein for 12 ft. in dacite formation. The ore assays $2 to $5 per ton. Faulting displaced the vein at 100 ft.

At the Pioneer Consolidated, 56 miles south of Goldfield, the outcrop of a good lode has been found 500 ft. from the main shaft. The mill will be ready in a week or so.

Humboldt County

The report of the Seven Troughs Coalition Mining Co. for the term ended June 15, 1915, has been issued. The income from gold was $362,540, other revenue made a total of $364,904. Mining cost $136,186, milling, $13,435, and all charges $199,749. Deducting administration and general expenses, etc., the net profit was $145,036. The surplus at the end of March, 1914, was $7554. Deducting dividend No. 2 of 2½%, or $36,076, and discount and brokerage $45,300, the surplus at April 30, 1915, was $71,629. The general manager, L. A. Freidman, states that the physical condition of the mine has never been excelled.

Lander County

Placer mining is yielding profitable results at Copper basin, Willow creek, and Copper canyon. A number of men are working, some getting rich returns. Up to June 1 the Rochester Mines Co.'s property has yielded 33,492 tons of ore valued at $826,944. This is from lessees and on company account.

Lyon County

In the suit of F. May *v.* the Nevada-Douglas Copper Co. for $40,000 for injuries received, the plaintiff was awarded $3000.

Nye County

Six mines and lessees (215 tons) at Tonopah last week produced 10,387 tons of ore valued at $212,926. Some May returns were as follows:

Mine.	Tons.	Ounces.	Profit.
Belmont	15,582	288,009	$92,587
Jim Butler	4,882	.....	48,793
Tonopah	12,300	216,300	62,175

The Jim Butler profits are a record for the mine. On June 21, Judge Averill heard a motion for a new trial in the Jim Butler-West End suit.——A new compressor has been installed at the Midway. Sinking has been resumed. Lessees (90 men) produced 130 tons last week.——Three sets of lessees are at the Montana. They shipped 190 tons last week.

The report of the Montana-Tonopah Mines Co. for the term September 1, 1913, to December 31, 1914, contains the following abstract from the superintendent's, A. H. Lowry, report: Work was continued at full time until November 15, 1914, when the mine and mill were closed, save for development. This was the result of the low price of silver and the grade of the ore mined. An agreement was made with the Midway company to enable work to be carried on in the old workings of the east part of the Midway ground. Development of the period totaled 11,793 ft., 1228 ft. being done in the Midway. The mill treated 63,755 tons of ore averaging $8.991 per ton. The revenue was $545,459 and net profit, $47,737, or 74.6c. per ton. Total costs were $7.784 per ton. Cash, silver advances, investments, and supplies were worth $338,431 at the end of 1914.

At Manhattan the organization meeting of the company to take over the Dexter White Caps Mining Co. has been held. At 270 ft. depth in the Little Grey claim the Nevada Mining & Development Co. lessees have opened the orebody for 100 ft. long and 30 ft. wide. The Manhattan Milling & Ore Co.'s 10-stamp mill is crushing the ore mined. New machinery for the Big Pine mill is arriving. When all is installed the daily output of ore will be increased to about 500 tons, of which 40% will be treated. The coarse material is screened and discarded, only the fine being tube-milled and amalgamated. The open-cut is 300 ft. long, 200 ft. deep, and 70 ft. wide. Recent developments have proved the ore-shoot to be 900 ft., averaging 40 ft. wide, and 200 ft. deep. The Big Four mine is to be re-opened. Kendall and Bragg of Goldfield have secured a lease on it. Prospects seem fair. The equipment includes a 10-stamp mill.

Storey County

At Gold Hill, on the Comstock lode, the Jacket-Crown Point Belcher Mines Co. has changed over its pumping plant from the Jacket incline to the joint incline in Belcher ground. This was well done, the water only rising a little. The pump is working smoothly at its new location and the water stands at about the 1500-ft. station. Considerable debris and muck remains to be removed at this point, after which the station will be timbered. When this is completed, the water will be lowered in the joint incline to a point below the 1600-ft. level, and the pumps recovered that have been submerged since the fire of last year. This work will make possible soon the starting of work again on the 1600-ft. of the Belcher, where an extensive body of quartz had been opened, and a large tonnage was being extracted daily.

White Pine County

According to the president of the Consolidated Copper Mines Co., C. H. Boynton, it is proposed to raise about $1,000,000 by sales of bonds, etc. Shipments of ore are being made to the Nevada Con. An experimental plant is to be installed in the old Giroux mill.

There were more accidents than usual at the Nevada Consolidated company's works in May. At Copper Flat were five disabling accidents in steam-shovel mining. Some were due to flying rock during blasting. Four men were injured at the mill, and ten at the smelter.

OREGON

Jackson County

(Special Correspondence.)—At Gold Hill the new Hardinge conical mill, with a capacity of 250 tons daily is working at the Braden mine. This is the only pebble-mill in southern Oregon. Its operation is creating considerable interest in the district. So far the machine has worked admirably. There is a large ore reserve in the Braden, and the new mill will be kept busy in the future. The old stamp-mill had a capacity of 150 tons. In addition to the new crushing-plant, much other machinery has been installed, including concentrators and cyanide plant.

Most of the Gold Hill placers have cleaned-up for the season. Though the run was short this year, the ground washed was unusually rich, giving as large a return as in former seasons. Among the larger hydraulic properties still in operation is the old Sterling, of Forest creek. This mine will have water till the middle of July. The Sterling has now been operated 50 years. The clean-up this season will be up to the usual value.

The French syndicate that owns the Bill Nye and adjoining claims is doing little development or other work this year, owing to the War.

The success of the Beaver Cement Co., operating the limestone quarries at Gold Hill, in the manufacture of lime and cement, together with the reports of the State Bureau of Mines on Jackson County limestones, has created an additional

interest in this industry. Practically all the cement used in the extensive hard-surface road building under way in southern Oregon comes from local manufacturers. This product had formerly to be shipped from distant points. The large quantity of limestone and marble in southern Oregon assures a big future for this industry.

Upper Applegate properties, in the vicinity of the Blue Ledge camp, are being given more attention this season than for the past five years. A number of claims that were abandoned two or three years ago, are again in the hands of original owners, and are being developed. Renewed activity in the Blue Ledge district, just over the line in California, has been largely responsible for this renewed interest. Most of these properties are low grade, the ores containing copper and gold.

Attention is again being given the cinnabar properties on the upper Rogue, near Trail. These veins contain commercial quantities of mercury. A difficulty has been a suitable method of reduction. The Butte Creek company was obliged to close on this account. Owners of upper Rogue cinnabar properties hope to solve the problem and ultimately operate the mines at a profit.

Gold Hill, June 20.

UTAH

The following dividends will be paid in July: on 1st, Daly-Judge (with extra) $75,000; Silver King Coalition, $187,000; Silver King Consolidated, $63,000; and Utah Copper, $1,648,000; and on the 26th, Utah Consolidated, $150,000. The total is $2,123,000.

Juab County

The Tintic district produced 142 cars of ore last week.

An electric hoist has been ordered for the Eagle & Blue Bell at Tintic. It is similar to that at the Daly West at Park City. The capacity is 50 tons per hour from 2500 ft. depth. Developments at 1750 ft. are excellent.

The May Day company has arranged another zinc contract. Zinc and lead-silver ore is being mined. The output in May was about $22,000, including lessees. The financial situation is satisfactory.

A cave about 30 ft. wide has been found in the Iron Blossom at 600 ft. It contains some lead and copper ores.

Piute County

For the $200,000 potash plant at Marysvale, Westinghouse, Church, and Kerr have secured a contract from the Mineral Products Co. Tenders have been received for a 7½-mile tramway from the mine to the mill. The F. C. Richmond Machinery Co. was given an order for three oil-driven air-compressors of 292-cu. ft. capacity each. They are made by the Chicago Pneumatic Tool Co.

Salt Lake County

With the flotation plant being installed, the Utah Apex company should increase its lead output from 30,000,000 to 40,000,000 lb. per year.——With the 50c. dividend to be paid on July 26 by the Utah Con., equal to $150,000, makes a total of $9,960,000.

The Cardiff mine is producing 100 tons of ore per day. Development continues highly satisfactory.——The Tar Baby adit is in 1716 ft. The advance is at the rate of 80 ft. per month through a quartzite formation. Copper stains are visible in the face. The quartzite-limestone contact is expected at any time.

Summit County

On July 1 the Daly-Judge will pay an extra dividend of $20,000. With the regular quarterly the total distributed will be $75,000. From 300 to 1400 ft. stoping is being done on the Daly vein. The mill is working two shifts. As high as $150 per ton was paid for the best zinc concentrate made.

Ore assaying up to 229.6 oz. silver, 56.4% lead, and $1.20 gold has been opened in the Revelator mine, in the Snake Creek district, south of Park City. The shoot occurs at a quartzite-limestone contact.

WASHINGTON

Spokane County

Dividends paid by companies operating in what is called the Inland Empire region of British Columbia, Idaho, and Washington, totaled $3,905,584 for the first half of 1915. They are as follows: Idaho—Bunker Hill & Sullivan, $490,000, Caledonia, $312,600, Federal, $240,000, Hecla, $90,000, Hercules, $1,000,000, Interstate-Callahan, $690,000, Stewart, $371,508, and Success, $105,000, a total of $3,299,608. British Columbia—Canadian Consolidated $232,176, Granby, $225,000, Hedley, $120,000, and Le Roi No. 2, $28,800, a total of $605,976.

Stevens County

The Copper King mine, near Chewelah, was put up for auction by the Receiver on June 12. J. W. Douglas bid $225,000, and Danson, Williams & Danson, $75,000. The mine has been well developed, has good equipment, and a 100-ton oil-burning smelter. The company has been in financial difficulties.

CANADA

British Columbia

A report of the Rambler-Cariboo Mines Co. for the year ended April 30, 1915, has been issued. Owing to the metal market situation it was decided to shut down in August 1914. The new superintendent, W. A. Cameron, reports that since January 1, 1915, 250 ft. of development has yielded good results. The mill is now working 20 hours per day, crushing about 2000 tons of ore per month. This yields 175 to 200 tons of lead concentrate, and about the same of zinc concentrate. Revenue during the period totaled $99,944, and all charges $94,619.

Spokane people with C. M. Smith have purchased the Portland-Lilly B. group of silver-lead claims at Slocan City, for $30,000. Development will commence in July, machinery being already installed for sinking to a depth of 1000 ft. The company is known as the Portland Silver-Lead Mines Co. It is authorized to issue capital stock to the amount of $250,000.

The British Columbia Copper Co. has started blowing-in its furnaces at Greenwood. The mine was closed just before the War started, but not on account of it, the reason being the low grade of the ore, and copper prices.

On June 30 the Hedley Gold Mining Co. will pay a dividend of 3%, and an additional one of 2%.

Ontario

A carload of ore weighing 43.58 tons, containing about 308,000 oz. silver, was shipped from the Temiskaming last week. This ore is from a new vein found during the winter.——The Nipissing company is to start hydraulic prospecting to the east side of Cart Lake. Work has been done on the west side of Peterson lake. In May the high and low-grade mills treated 177 tons and 7016 tons of ore respectively, yielding $175,522. The refinery shipped 553,007 oz. silver. Hydraulicking uncovered a narrow low-grade vein 50 ft. long, with a good deal of silver in the wall-rock.

The Tough-Oakes at Kirkland Lake is treating 80 tons of $20 ore per day. The May output was 2400 tons for over $55,000. Fourteen machines are working underground. Sinking to 400 ft. is underway.

In May the Alexo nickel mine shipped 982 tons of ore.

The Crown Reserve company will continue to negotiate for the property it had under option in Nicaragua. It contains large low-grade ore deposits.

For the year ended April 30, 1915, the Buffalo Mines Co. reports that the output was 822,791 oz. silver. The income was $460,657; surplus after dividends, $27,059; and total surplus, $379,969. Corresponding figures for 1913-1914 were $974,082, $270,219 (deficit), and $352,809.

YUKON

The Canadian Klondyke and Yukon companies have their dredges and hydraulic plants in full operation

KOREA

The Seoul Mining Co., operating the Suan concession in Whang Hai province, reports the following results for May

Ore treated, tons	7,020
Mill operating, days	29.25
Total recovery	$80,580
Operating expenses	27,500
Net earnings	53,080

The May clean-up of the Oriental Consolidated yielded $154,231. Details of April return are as follows ore treated, 22,564 tons; total bullion recovered, $139,298. Taracol cyanide-plant extraction, 92.1%; Maibong tube-mill plant, 95.2%; and there is still trouble with the freight bulls with the foot-and-mouth disease.

MEXICO

CHIHUAHUA

On September 7, 1914, the American staff of the Batopilas Mining Co. arrived at the property. Operations have been continuous since. Bullion shipments have been made regularly. Reports for the years 1913 and 1914 will soon be available.

SONORA

A number of small mining properties in this State, supplied by the Nacozari railway, are short of explosives. This line has been closed temporarily, and the Moctezuma Copper Co. will not sell any more powder until the road resumes. There is food in Nacozari for about a month. The United Mines Co., operating the North Tigre has closed.

It is reported in Douglas that two blast and one reverberatory-furnace at Cananea have been blown-in, after a stoppage of 10 months. L. D. Ricketts left Bisbee for the smelter on June 16. The concentrating plant is not in operation yet.

NICARAGUA

H. P. Henderson, F. H. Sistermans, and D. M. Munro were in Bluefields at the beginning of June, on their way to the Potosi mine. They will examine it for the Tonopah Belmont Development Co. of Nevada.

PHILIPPINE ISLANDS

In the Philippine *Journal of Science* for January, a preliminary check list of Philippine minerals is given. This was compiled by Warren D. Smith, F. T. Eddingfield, and Paul R. Fanning. There are 113 mineral species known to occur in the territory. The list briefly describes them and their occurrence.

Schools and Societies

PRINCETON UNIVERSITY held its 168th commencement on June 17.

The UNIVERSITY OF CALIFORNIA summer session commenced on June 21. About 4900 students are enrolled.

The UNIVERSITY OF WASHINGTON has issued a bulletin dealing with its College of Mines. The faculty of the department consists of 36 instructors and assistants. The summer session opens June 21 and ends July 31.

The UNITED ENGINEERING SOCIETY has established a Library Service Bureau which will furnish to engineers accurate abstracts and reliable translations of articles appearing in any language; to compile bibliographies on any engineering subject; to supply copies of articles, and to make photostatic prints of diagrams, maps, plates or printed pages. To save bookkeeping, engineers are invited to subscribe to the Bureau, and the subscription will be credited to service rendered. A list of charges will be sent in request, addressed to 29 West 39th St., New York.

PERSONAL

JOHN B. FARISH is here.

THOMAS T. READ is at Engels.

H. R. PLATT is at Stewart, B. C.

A. MCARTHUR JOHNSTON is in London.

W. S. NOYES has returned from Texas.

C. W. MERRILL has returned from New York.

T. WALTER BEAM, of Denver, is at Camp Hedley, B. C.

H. W. DUBOIS sails from Seattle for Alaska on June 30.

H. C. WILMOT is in New York city on professional work

W. J. ELMENDORF has left Fairbanks to go to Kantishna, Alaska.

JOHN B. HASTINGS has returned from Yellow Jacket, Idaho, to New York.

CHARLES JANIN will leave next week for an extended professional trip.

OSCAR H. HERSHEY is expected at Kellogg, Idaho, on his return from Alaska.

JAMES MACTEAR has resigned from the firm of W. R. Feldtmann & Co., London.

EDWARD A. CLARK and CHARLES HAYDEN, of Boston, are at the St. Francis hotel.

B. H. DUNSHEE has been spending a holiday at Berkeley and has gone to San Diego.

D'ARCY WEATHERBE sails from New York for Liverpool by the *Tuscania* on June 26.

A. D. MILES, president of the Canadian Copper Co., has been visiting San Mateo, California.

M. E. PURCELL, manager of the Centre Star and War Eagle mines, Rossland, visited the Exposition.

H. E. CRAWFORD, of the Cinco Minas, and WILLIAM HOWARD, of the Amparo mine, are in San Francisco.

GEORGE E. FARISH is on his way from New York to examine the Copper Basin group in southern California.

ROBERT I. KERR, of Jackson, has been appointed secretary-treasurer of the California Metal Producers Association.

E. C. KLINKER, manager for the Columbia Consolidated Mines Co., near Nevada City, was in San Francisco recently.

G. H. COX, in the department of geology, the Missouri School of Mines, is spending the summer in visiting the oilfields of California.

TAKESHI KAWAMURI, metallurgist for the Mitsu Bishi Co., passed through San Francisco on his way to visit steel plants in the Eastern United States and England.

SAMUEL W. COHEN has just returned to Cobalt from a three months' trip to Nicaragua, where he was engaged in the examination of gold mines under option to the Crown Reserve Mining Co. Assisting him in the examination were E. L. STEINDLER, A. BURNETT, H. BISCHOFF, and G. MILLER.

Obituary

J. G. PARMENTER, of Los Angeles, was assassinated at the El Favor mine, near Guadalajara, Mexico, on May 26.

WILLIAM C. HUNTER, who was examining the Columbia Consolidated in Nevada county, California, was killed two weeks ago by the explosion of a misfired hole.

JOHN A. FINCH, aged 61, well known in mining circles in Idaho, Washington, and British Columbia, died suddenly of apoplexy at Spokane on June 20. He was born in England, arriving in the United States when three years old. In 1881 he started in mining business at Denver and Leadville, going to Idaho six years later. His interests recently included the Gem mine and Federal company in the Coeur d'Alene, Standard, Enterprise, St. Eugene, and War Eagle in British Columbia, and the Kendall in Montana; also in several California properties. His wife survives him.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, June 24.

Antimony	—35¾
Electrolytic copper	20½—20¾
Pig lead	6.00— 6.95
Quicksilver (per flask)	$95
Spelter	25 —25¼
Tin	39½—41
Zinc-dust, 100-kg. zinc-lined cases	30

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, June 24.—Copper is quiet and waiting; lead consumers are now offering to sell; spelter has few buyers, but is firm.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date		Average week ending	
June 17	49.12	May 12	50.06
" 18	49.12	" 19	49.93
" 19	49.12	" 26	49.77
" 20 Sunday		June 2	49.40
" 21	49.00	" 9	49 35
" 22	48.87	" 16	49.31
" 23	48.62	" 23	48.97

Monthly averages.

	1914.	1915.		1914.	1915.
Jan.	67.58	48.85	July	54.90	....
Feb.	67.53	48.45	Aug.	54 35	....
Mch.	58.01	50.61	Sept.	53.75	....
Apr.	58 52	50.25	Oct.	51.12	....
May	58.21	49.87	Nov.	49.12	....
June	56.43	....	Dec.	49.27	....

The above quotations indicate a decided weakness. London advises that the market has had a relapse into dullness. It would seem as if the bullish activity in the Indian Bazaars has not acquired as yet much staying power, more especially as it has had to absorb not only the ordinary volume of sales in London, but also an amount of selling from China as well. On some purchases for China the price rallied recently, but as inquiries were not maintained, prices receded. Up to June 3 exports of silver from London to the East were approximately 11,500,000 oz. less than in the same period of 1914. On June 19 there was about 40,000 oz. sent from San Francisco to China. The feature of the market has been the small amount offering at the present level. If continued, this may have some effect upon the price, for Continental demand is not absent—though certainly slight just now—and in these circumstances, there is not much available for other quarters.

TIN

Prices in New York, in cents per pound.

The Copper Range Consolidated has sold 1,000,000 lb. at 20.5c. and 2,000,000 lb at 20.25c. Anaconda has declared a dividend of 50c. per share, an increase of 25c. Osceola will distribute $3 per share.

Exports of copper during the week ended June 5 totaled 13,180,318 lb., valued at $2,396,030. Of this, 6,251,444 lb. went to France, 4,318,068 lb. to Italy, 2,232,933 lb. to England, and 224,036 lb. to Switzerland. Imports of ore, matte, pigs, bars, etc., amounted to 9,161,398 lb., valued at $1,329,421.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
May 27	75.00	June 9	90.00
June 2	80.00	" 16	90.00
		" 23	95 00

June	38.60	....	Dec.	53.10	....

Exports of mercury from San Francisco during May totaled 220 flasks, against 240 in that month of 1914. Of the former quantity, 200 went to New York, 14 to Korea, 3 to Nicaragua, 2 to Mexico, and 1 to Canada. London price is now £14, equal to $67.20 per flask.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

On the next page it is mentioned that the U. S. Steel Corporation will erect a zinc smelter near Pittsburg. This concern uses about 75,000 tons of spelter in a normal year.

In May the Butte & Superior mine had the following return: ore treated, 42,380 tons; average zinc content, 16.58%; concentrate saved, 11,870 tons; average assay, 52.11% zinc; contents of concentrate, 12,371,000 lb. of spelter; and recovery, 88.03%.

The United States consul at Yokohama reports that the Mitsui Bussan Kaisha has arranged for supplies of zinc ore and will erect a smelter. Two plants are in operation at present.

ANTIMONY

Consular advice from Hankow, China, states that shipments of antimony regulus and crude antimony during the first three months of 1915 were 1067 and 2560 tons respectively. In 1914 the district totaled 25,413 tons, valued at $768,935.

Eastern Metal Market

New York, June 18.

The week brought surprises in the steady decline of spelter, and in the collapse of the lead market. There are now more offerings of spelter than there are buyers, and the same is true, only to a more marked extent, in lead. In the latter, consumers who had heavily over-bought while in a state bordering on panic, were later almost as frantic in their efforts to sell. Brokers were loaded with commissions to sell at the best price they could get. The situation in both metals savors of artificiality. The United States Steel Corporation announces that it will build a smelter at Pittsburg, to be ready for operation at the end of this year. The course of copper, which has softened a little in a dull market, is the most sane of any of the metals. In the opinion of careful observers, those interested in the metals should remember that fulfillment of the tremendous orders which have been placed in this country for shrapnel, explosive shells, and other munitions of war is only just beginning to get into full swing. Some of the big plants to be devoted to that form of work are not yet completed, while others are not yet organized. Of course, much depends, so far as the metal markets are concerned, on how far contracts have been made for the copper, lead, and spelter, also antimony, which will be required.

The makers of hand and automatic screw-machines, much used in making small parts, including shrapnel fuse-timers, from brass bar-stock, are sold up for months to come, and turning business away. Firms which do a jobbing business with such machines are reaping a harvest. Collections were never better with the machinery trade, with the war order substantial amounts are paid cheerfully in advance. It is satisfactory to note that the war business is steadily extending to other lines. More interest in equipment and supplies is being shown by railroads.

COPPER

Buying to fill war requirements was fairly active in the latter part of last week, but since then an admitted lull has settled over the market. With the better activity prices of electrolytic advanced until 19.87½c., cash, was reached June 10 and the quotation exceeded 20c. cash New York, two days later. When buying ceased there still was a large amount of inquiry in the market, and presumably it represents demand that yet must be satisfied. The lack of interest brought about lower quotations both here and abroad, but offerings of re-sale lots at concessions did not tempt buyers to any appreciable degree. The quotations for prompt delivery June 18 were 19.87½ to 20c., cash, New York. Good brands of Lake were quoted June 18 at 20.25c. Very choice grades, which are out of the market, are nominally quoted up to 23c., and even 24c. While copper shows some temporary weakness it is unquestionably in a better position than spelter or lead. The exports this month total 11,700 tons.

LEAD

On Monday of this week the lead market collapsed. The American Smelting & Refining Co. was holding, on that day, to its price of 7c. New York, which had been established June 12. Up to this day the outside market was extremely strong, and up to 7.75c. was asked by independents. On June 14, all kinds of holders of lead—producers, retailers, jobbers, and even consumers—took it into their heads to sell, and the numerous offerings caused the price to decline. The metal could easily be bought at 6.25c., June 16, and the following day the largest interest reduced its New York quotation to that figure; while outsiders came down to 6c. On June 18, the quotation of the largest interest was 6c. and those of independents, 5.75 to 6c. For days the New York price was above St. Louis parity. Despite the curious trend of prices it is still insisted that surplus stocks have been greatly reduced, and that current consumption will be henceforth drawn upon to a greater degree to meet demand. Again that statement is challenged. Whatever the causes of the market's course, old observers say they have not seen its like in 40 years. The excitement was started by heavy European buying followed by a rush on the part of domestic consumers. Many of the latter over-bought and so were eager to sell when the tide turned. The exports up to June 19 totaled 5088 tons.

SPELTER

E. H. Gary, chairman of the board of directors of the U. S. Steel Corporation, issued the following statement June 18: "We have decided to build near Pittsburg, probably at Donora, a new plant for the manufacture of zinc and by-products, including sulphuric acid, at a cost of from $2,500,000 to $3,000,000. We have, for some years, been considering the building of such a plant in order to supply materials for our own use. We have been buying of other manufacturers but as there has been some difficulty or, at least, delay in supplying our necessities, we have reached the conclusion to proceed at this time.

"The market for the products of the plant is largely in the Pittsburg district, and for this reason and the further reason that it is a good point for the assembly of raw materials, we have selected this location. We hope to be able to start operations on or before the first of next January."

For the present, at least, the tide has turned in the spelter market, and since June 9 the trend of prices has been steadily downward. The producers have shown no anxiety to sell, but second-hands and consumers have made offerings at lower and lower prices, until yesterday 19.50c. was quoted. The entire situation is one where buyers, in a state of panic bid the market up on themselves, then turned round and offered the metal at successively lower prices. First there were many buyers and few sellers, then many sellers and few buyers. It is interesting to note that on June 14 an English buyer offered 23c. for 100 tons of September and October delivery, but a producer to whom the offer was made was willing to sell but 50 tons on that basis. Sales for July delivery were made early in the week at 21c. Despite the decline in the market the makers of galvanized sheets seem to have found no relief. On June 17 they advanced their quotations $5 per ton, making the total increase of $10 within a week. Meanwhile more plants are withdrawing from the galvanizing trade. The prevailing price of 5c. for No. 28 galvanized sheets is prohibitive for many uses. An advance in galvanized pipe is predicted. With the decline in spelter, sheet zinc was reduced June 14 from 33 to 30c. The exports of spelter, up to June 19 totaled 1021 tons.

TIN

The feature in tin at this writing is the scarcity of spot stocks, which caused the quotation for prompt delivery metal to advance to 24.25c., June 15. Late last week there was a good business in early shipment from London and from the Straits. Immediately after interest subsided and prices declined. The quotation June 14 was 41.25c., and yesterday it was 41c. The market is irregular because of the variations in the value which different holders place on the metal. There are not many sellers at this time. Few arrivals of importance are promised for this month. The aggregate up to today is 1530 tons. There is afloat 6182 tons.

ALUMINUM

Quotations range from 30 to 32c., but it must be understood that large consumers got their supply at lower figures, probably around 20 cents.

MINING DECISIONS

Mining Partnership—Termination

Where joint owners of an oil and gas lease unite in operating the demised premises thereunder without any special agreement as to the character of their relation to each other, they constitute a mining partnership, and such partnership is not terminated by the execution by one partner of a deed of trust on his partnership interest to secure his co-partner in a loan based on a transaction outside of the firm business.

Wetzel v. Jones (West Virginia), 84 Southeastern, 951. April 20, 1915.

Oil Lease—Abandonment and Cancellation

Where, in a suit to compel defendants to drill an oil-well, or abandon the premises comprised in an oil and gas lease, it appeared that the lessee, after drilling one well, failed for 13 years to explore the premises further, and had no intention of drilling additional wells, even though the lessee was of the opinion that such wells would not be profitable, it was held that the lease should be cancelled as to all but a small area surrounding the drilled well.

Highfield Co. v. Kirk (Pennsylvania), 93 Atlantic, 815. January 11, 1915.

Mining Lease—Construction of Covenants

A covenant to explore and mine is not necessarily implied in a lease of property to be paid for in royalties. But even if such a covenant were implied and the lessee failed to perform, it does not follow that the right to forfeit the lease arises. The right of forfeiture is confined to the failure of the lessee respecting covenants and conditions which are 'expressed in the lease,' and does not arise upon the non-observance of an implied covenant or condition.

A covenant for 'thorough exploration' for iron ore does not require the lessee to operate the mine, but merely requires a complete search to determine whether the land contains ore, and if so, the boundaries and character of the deposits. The right to remove ore which has been mined may be implied from the terms of the lease providing for methods of weighing, payment of minimum royalties, etc.

De Grasse v. Verona Mining Co. (Michigan), 152 Northwestern, 242. April 19, 1915.

Assessment Work—Resumption Prior to Forfeiture Re-location Notice

Where the owner of several mining claims failed to perform assessment work thereon for the year 1912, but early in 1913 expended large sums in constructing trails and cable lines leading to the claims, the performance of this work sufficed to prevent a forfeiture to a subsequent re-locator, even though said trails and cable lines were also intended to be used in the construction of a railroad to carry the ore to market. The location notice posted by the would-be locator was fatally defective because it did not contain a statement that he was relocating forfeited or abandoned ground. It is insufficient if only the recorded notice contains this statement. The Federal law contains no provision for the recording of notices, but the State laws, placing additional requirements upon locators are to be construed as 'statutes of peace and repose intended to prevent disorder in claiming and holding mining claims,' and must be followed. Hence, owing to the resumption of work by the original locator prior to the alleged re-location, and to the insufficiency of the posted notice of re-location the re-location was held invalid.

Florence-Rae Copper Co. v. Kimbel (Washington), 147 Pacific, 881. April 17, 1915.

COMPANY REPORTS

DOME MINES CO., LTD.

Accompanied by plans and photographs of its property, the Dome Mines Co., Ltd., has issued a report for the year ended March 31, 1915. The statement of the general manager, C. D. Kaeding, includes the following: Development to No. 6 level amounted to 12,098 ft., including 5875 ft. of diamond-drilling. Stations, enlarging drifts, etc., totaled 85,000 cu. ft. This work cost $173,319, equal to 69.7c. per ton of ore treated. Development was distributed within a zone 400 ft. wide by 1500 ft. long. Ore reserves are estimated at 2,782,811 tons, averaging $4.15 per ton. There has been developed a body of better grade ore on No. 4 and 5 levels, similar to that originally milled from the so-called 'dome.' The apex is at No. 3 level, 260 ft. from the surface. On No. 4 level it is 120 by 330 ft., and on No. 5, is 60 by 160 ft. Drilling below this to No. 6 a vertical distance of 130 ft. indicates more ore. A system of shrinkage stopes has been prepared on No. 3 and 5 levels.

In August, additions to the mill were completed, and connected with the old units. The plant treated 248,550 tons averaging $4.68 per ton. The recovery was 90.6%, bullion extracted being $1,055,497. Costs were 99c. per ton, including some alterations, a reduction of 45c. per ton.

Mining, treatment, and other charges totaled $2.967 per ton, a decrease of $1.23 per ton. The operating profit was $315,179. Deducting depreciation, repairs and improvements, there was left $175,578. The surplus on April 1, 1914, was $486,520, and on that date of 1915, $665,099.

SEOUL MINING COMPANY

The 52 pages of the detailed and interesting report of this company for the year ended December 31, 1914, includes the directors' report, balance sheet and accounts, reports of the general manager, A. H. Collbran, electric-power by H. Maki, Tul Mi Chung mine by E. W. Mills, prospecting progress by E. W. Mills, and the Soctaire and other prospects by K. I. Yun.

To erect the mill at the Tul Mi Chung and for further development, the company borrowed $250,000 from shareholders. Dividends amounted to 50% of the capital, equal to $250,000. The year commenced with a balance of $188,412, and ended with one of $252,106.

Development at the Suan mine covered 7138 ft., making 35,701 ft. to date. A large flow of water was encountered on No. 6 level, making work impossible, so a new pump is being installed. It was also necessary to draw on the broken ore reserves, reducing them from 53,335 to 35,606 tons. Ore reserves are estimated at 236,536 tons having the following metal content: gold, $9.13 per ton; copper, 1.12%; and bismuth, 1.7 lb. per ton, the total value being $12.86 per ton at normal prices of these metals. The central orebody is worked out. The western shoot was reduced from 19,750 to 7670 tons. Mining cost $1.38 per ton, a decrease of 46c. per ton. The mill worked 338.6 days, or 92.77% of the possible time. It treated 74,550 tons of ore, yielding gold, copper, and bismuth worth $563,348, $91,859, and $35,974 respectively. Recovery of gold and copper was 85.98% and 56.24%. Flotation is now increasing this extraction. Treatment cost $1 per ton. All costs were $3.90, a reduction of 43c. per ton.

At the Tul Mi Chung mine development totaled 11,958 ft., making 22,172 ft. to date. Two new orebodies were developed, making seven. Reserves amount to 963,600 tons assaying $8.14 gold, 1.59% copper, and 0.8 oz. silver per ton, a total value of $11,904,645. Grading for the new 300-ton mill was finished in April 1915.

A considerable amount of work was done at many districts on gold-copper and silver-lead-zinc ores.

New Machines and Devices

Information based on letters and catalogues from manufacturers

Mining in the City of New York

The illustration below is not of open-cut operations on the Michigan iron ranges nor the starting of a shaft in a Western mining district, but shows mining going on within a few blocks of Wall Street. So far as mining operations, rather than products, is concerned, New York is one of the great districts of the world, for its water-supply system, now nearly completed, and the numerous subways now in course of construction involve an amount of underground work which for extent compares favorably with the largest mining operations, and introduces many complex problems through the necessity of carrying on work without interfering with the traffic of the city. The illustration above shows drilling in progress in an open-cut for the new subway system, and was furnished by the courtesy of the Ingersoll-Rand Company.

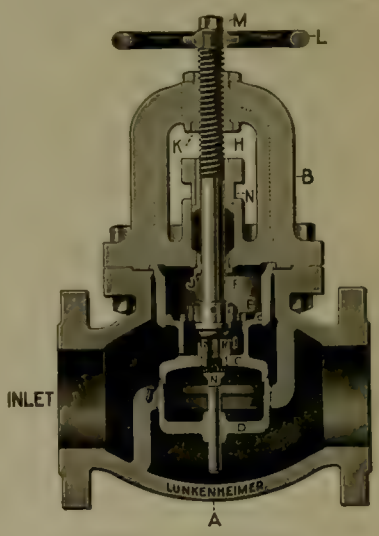
MINING IN NEW YORK CITY.

An Improved Balanced Throttle-Valve

A valve of exceptionally free and easy operation combined with efficiency is necessary for engine-throttle purposes. The valve illustrated was designed, with this important object in view, by the Lunkenheimer Co., Cincinnati. Its construction embraces all the essentials necessary for the highest type of engine throttle, and is claimed as being a most reliable valve of exceptional durability. An important factor of this valve is in the simplicity of its design. No small parts of uncertain reliability or strength are embodied in its construction. There are practically but three moving parts, the main disc, by-pass disc, and stem. These being of large proportion, will safely withstand the hardest service to which valves of this type are subjected. With ease of operation, follows lack of friction, and as practically no force is required to open or close the valve, wear on all moving parts is reduced to a minimum. This ease of operation is directly attributed to the improved by-pass construction, which equalizes the pressure on both sides of the disc.

The operation of the valve is as follows: assume that the valve is closed and under pressure. As pressure will enter the balancing cylinder, by passing the piston-ring and also entering through the small hole in the bottom of the disc-cylinder, the pressure above the disc is equal to that in the inlet of the valve. This pressure aids materially in holding the disc C tightly to its seat, but unless some provision was made to relieve this pressure, the valve would be extremely difficult to open.

The method of relief lies in the by-pass I, the opening through which is covered by the bottom of the stem H when the valve is closed. A slight turn of the hand-wheel, however, uncovers this opening and the steam above the piston will then pass through the holes in the retaining ring E, thence through the hole in the by-pass disc I and holes in the main disc guide stem N, immediately relieving the pressure above the piston. Any pressure that may escape past the piston ring or through the small hole in the bottom of the disc-cylinder, is also quickly relieved while the valve is being opened. There being practically no pressure above the disc, the operation of opening the valve is therefore an exceedingly easy one.



BALANCED THROTTLE-VALVE.

The main object of the small hole in the bottom of the disc-cylinder, is to drain water from condensation that may accumulate when the valve is connected in a horizontal position, with the hand-wheel up. When in a horizontal position, any water in the disc and balancing-cylinders will drain past the piston-ring.

Both the main and by-pass disc are operated simultaneously by one movement of a single hand-wheel, which not only facilitates the quick operation of the valve, but insures the opening of the by-pass valve at the proper time. Provision is made for re-grinding both the main and by-pass disc seating-surfaces, should they become worn. As all parts are renewable, the durability of the valve is increased. Expansion or strains may slightly distort the seat, but owing to the annular extensions

on both the seat and disc, which provide spring seating-surfaces, they will regularly accommodate themselves to any slight irregularity, and therefore a tight valve is at all times assured. The body may be tapped anywhere above the seat or inlet end for drain connection, so that any water from condensation can be removed before the valve is opened. For the lubrication of the engine-cylinder, the body can also be tapped on the inlet or outlet end, to which lubricator connection may be made.

This improved valve is made in sizes ranging from 4 to 10 in. inclusive. To suit various conditions of superheat and pressure and to meet the specifications of engineers who differ as to the materials used for the different parts, they are made in six combinations.

The manufacturers have issued an attractive booklet illustrating and describing the new valve.

Mining Machinery Exhibitors at the Exposition

In the Palace of Mines and Metallurgy the following firms are represented: Braun-Knecht-Heimann Co., San Francisco, assaying apparatus; Joshua Hendy Iron Works, San Francisco, safety mine-cage; Denver Engineering Works, head-frame and electric-hoist; Koehler Manufacturing Co., Marlboro, Massachusetts, safety-lamps; Byron Jackson Iron Works, San Francisco, centrifugal mine pump and winze pump; General Machinery & Supply Co., San Francisco, single-stage air-compressor and receiver; Goodyear Tire & Rubber Co., Akron, Ohio, air and water hose; Hendrie & Bolthoff Manufacturing & Supply Co., Denver, drill-column; Coast Manufacturing & Supply Co., Livermore, California, safety fuses; Hercules Powder Co., Wilmington, Delaware, explosives; Westinghouse Electric & Manufacturing Co., East Pittsburg, storage-battery mine locomotive and trolley-gathering locomotive, and motors; Baltimore Enamel & Novelty Co., Baltimore, enamel signs; Hockensmith Wheel & Mine Car Co., Penns Station, Pennsylvania, mine cars; Pyrene Manufacturing Co., New York, fire extinguishers; American Blower Co., Detroit, mine fans; American Mine Door Co., Canton, Ohio, automatic mine doors, manway doors, and plain swinging doors; Riverside Portland Cement Co., Los Angeles, cement for floor and walls; Ensign-Bickford Co., Simsbury, Connecticut, safety fuse; MINING AND SCIENTIFIC PRESS, San Francisco, technical publications; Western Electric Co., New York, portable electric mine telephone; Concordia Safety Lamp Co., Pittsburg, Pennsylvania, electric mine lamps; Life Saving Devices Co., Chicago, artificial respiratory apparatus; Jeffrey Manufacturing Co., Columbus, Ohio, breast turret coal mining machine, and truck and turret coal-cutting machine; Linde Air Products Co., New York, oxygen for rescue demonstrations; Superior Oxygen Co., Pittsburg; Dunham, Carrigan & Hayden Co., San Francisco, wheelbarrows, picks, and shovels; Cyclone Drill Co., Orrville, Ohio, working model; John Simmons Co., New York, carbide hand and cap lamps; Denver Rock Drill Co., Denver, stoping, sinking, and drift drills; Ingersoll-Rand Co., New York, Jackhamers, stoping-drills, water-feed hammer-drills, piston-drills, stretcher-bar hoist, drill-sharpener, and oil-fired forge; Draeger Oxygen Apparatus Co., Pittsburg, three sets artificial breathing equipment and oxygen pump; Gould Manufacturing Co., San Francisco, electric ditch pump; Mine Safety Appliances Co., Pittsburg, artificial breathing apparatus, safety-lamp testing and demonstrating box, recording volumeter, recording hydro air-pressure gauge for fan, and first-aid materials; The White Co., Cleveland, rescue auto-truck; H. R. Worthington, San Francisco, vertical direct-connected sump pump; Thos. A. Edison, West Orange, New Jersey, electric mine lamp, approved by the U. S. Bureau of Mines; Senn Concentrator Co., Oakland, California; Oliver Continuous Filter Co., San Francisco; Hardinge Conical Mill Co., New York; Dorr Cyanide Machinery Co., Denver; and Merrill Metallurgical Co., San Francisco; and the L. C. Trent Engineering Co. of Los Angeles, apparatus for ore-treatment. The Trent tanks are made by the Redwood Manufacturing Co. of San Francisco.

Boilers at the Exposition

One of the most prominent features of the exhibit of Babcock & Wilcox Co., in the Palace of Machinery at the Panama-Pacific Exposition, is a boiler exhibited by the company in 1876 at the Centennial Exposition at Philadelphia. The boiler thus forms an interesting link between the two expositions, showing the progress in methods of construction of water-tube boilers in the interval. The exhibit includes three boilers to represent the land type, all with brick settings according to approved practice, half the setting being removed to allow an examination of the boiler. One of these is the well-known water-tube boiler with vertical headers. It is fitted with an oil-burning furnace. Boilers of this type now in use in different parts of the world are capable of generating 10,000,000 horse-power. Less common, but nevertheless, widely used, is the Stirling boiler. The Rust boiler has also been found satisfactory under a variety of conditions.

Commercial Paragraphs

The YUBA CONSTRUCTION CO. at Marysville has secured a contract from the Yuba Consolidated Gold Fields Co. to construct a dredge. It will be larger than No. 14 now operating on the Yuba river.

The TERRY STEAM TURBINE CO., Hartford, Connecticut, announces the appointment of Joseph Battles as district sales manager for Denver, covering the states of New Mexico, Colorado, Wyoming, and the western portions of Nebraska. His address is 326 First National Bank building, Denver.

The ROBINS CONVEYING BELT CO. has issued a folder on its 'Durabelt,' 'Everwear, 'Supreme,' and 'Equator' belts. A 36-in. Durabelt carried over 6,000,000 tons of coal, a 44-in. over 4,000,000 tons of limestone, while an 18-in. carried coal for 17 years.

The HOLT MANUFACTURING CO., Stockton, California, announces that it has been awarded two grand prizes, five medals of honor, and two gold medals for its exhibit at the Exposition. The medals of honor indicate scorings of 95% or over. A grand prize was given on the 'Caterpillar' tractor, well-known to mining men.

The INGERSOLL-RAND CO., New York, announces that on July 1 it will open a branch office at 139 Townsend street, San Francisco. H. L. Terwilliger will be in charge, his duties covering this and the Los Angeles districts. On July 22 the agency contract of Harron, Rickard & McCone expires, but arrangements have been made whereby they co-operate in the sale of I.-R. machinery after that date.

The Case low-pressure oil-forge for heating drill-steel is described in a leaflet issued by the DENVER FIRE CLAY CO., Denver, Colorado. It is claimed for this furnace that it uses less ounces of air pressure thoroughly to atomize the oil than other burners require pounds of air pressure. The constant pressure is 6 oz. The fan to supply the air to atomize the oil within the Case burner is direct connected to a General Electric motor. Other claims are as follows: no sulphur on drill being heated, drill under observation, drill holds edge longer, practically no noise or smoke, and no scale forms on drills.

The CHICAGO PNEUMATIC TOOL CO., with offices in the Fisher building, Chicago, and 52 Vanderbilt St., New York, has issued Bulletin 34-X, dated May 1915, relating to its class A-G 'Giant' gas and gasoline engines. The publication illustrates these engines in six sizes, ranging from 16 to 130 hp. The engines are similar in general design to the well-known Giant fuel-oil driven engine manufactured by the same company, with the exception that they are designed for operation with manufactured or natural gas. The firm claims that the enclosed self-oiling features, extreme simplicity, and perfect automatic regulation should recommend them throughout the field where manufactured or natural gas is available for power purposes.
